THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XV.

FROM MAY 15 TO NOVEMBER 6, 1885.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1885.

May - Nov.
1885

INDEX TO VOL. XV.

A

Abney, Cap., Colour Mixtures, 162.
Adams, Prof. W. G., Electric Light and Atmospheric Absorption, 362, 331.
Alternating Currents, by T. H. Blakesley, 22, 58, 114, 164, 390.
Alternating Currents for Measuring Liquid Resistances, 450.
Aluminium by Electrolysis, 456.
Alums, Specific Refraction of, 161.
Ammeter, Cunynghame's, 295.
Ammeter, Dr. Aron's, 318.
Ammeter, Sir W. Thomson's Gravitational, 396.
Anderson, J., and A. E. Kennelly, Localising a Partial Earth in a Cable, 177.
Anglo-Continental Telephone Company, 478.
Arc and Incandescent Lamps in parallel, 296, 326.
Arc Lamps at Philadelphia, Report on, 104.
Armstrong, Prof. H. E., Address to Chemical Section B.A., Aberdeen Meeting, 398, 416.
Atlantic Cable, The Pioneer, 238.
Atmospheric Electricity, 63, 359.
Ayrton and Perry, Profs., on Voltmeters, 161.

B

Baines, A. E., The Insulation Test (*see* SUPPLEMENT for July 3).
Batteries, Primary :—
  Automatic Bichromate, 181.
  Bazin's Rotative, 200.
  Daniell's, Relation between E.M.F. and Zinc Solution, by H. S. Carhart, 69.
  Influence of External on Internal Resistance, by Dr. G. Gore, 279.
  Kauffer and Goldner's, 260.
  Modification of Daniell's, by J. J. Coleman, 410.
  Standard Form of Daniell's, by Dr. Fleming, 161, 232, 255.
  (*see* also VOLTAIC CELL & CORRESPONDENCE.)
Batteries, Secondary :—
  The Charging of, by W. H. Preece, 42.
  For Electric Lighting, 181, 200.
  Glaesener's, 200.
  By F. G. Howard, 99.
  Leading Article on Howard's Paper, 98.
Bazin's Rotative Battery, 200.
Berthon's Microphone, 212.
Bichromate Battery, Automatic, 181.
Bidwell, S., Action of Light on Selenium, 49.
Bidwell, S., Action of Light on Selenium and Sulphur Cells, 161, 162, 356.
Bidwell, S., Sulphur Cell with Solid Electrolyte, 355.
Bidwell, S., Variations in Length of Iron, &c., caused by Magnetisation, 49.
Blakesley, T. H., Alternating Currents, 22, 58, 114, 154, 390.
Blyth, Prof. J., New Form of Galvanometer, 413.
Bottomley, J. T., Contact Electricity, 377.
Bottomley, J. T., Cooling Wires in Air and Vacuum, 378.
Bottomley, J. T., Resistance of Platinoid, 125.
Bottomley, J. T., Unmagnetisable Steel, 378.
Bouty and Foussereau, Use of Alternate Currents for Measuring Liquid Resistances, 450.
Brake, Brauer's, 191.
Braun, E., Thermo-Electric Test of Molten Metals, 83.
Brazilian Submarine Telegraph Co., Re, 86.
British Association at Aberdeen, Leading Article), 330.
British Association Meeting (*see* SOCIETIES' MEETINGS).
"Britannia" cable ship, Inspection of, 121.
Buchanan, J., Thermo-Electric Position of Carbon, 162.
Bucharest Theatre, Electric Light at, 140.
Business Notices, 72, 128, 164, 300.

C

Cable, Localising Partial Earth in, by J. Anderson and A. E. Kennelly, 177.
Cable, The Pioneer, Dinner Given by Cyrus Field, 238.
Cable Stories Retold, by F. C. Webb, 65, 423.
Cables, The Insulation Test for, by A. E. Baines (*see* SUPPLEMENT for July 3).
Cables, Military, in the Far East (Leading Article), 62.
Cables Protection Bill, 156, 216, 233, 234.
Cables, Their Purchase by the Government (Leading Article), 292.
Cable ship, New, The "Britannia," 121.
Cantor Lectures (*see* FORBES).
Carbon Compounds, Conductivity of, 124.
Carbon, Thermo-Electric Position of, 162.
Carbons, Report on those Shown at Philadelphia, 124, 162.
Carhart, H. S., Relation Between E.M.F. of Daniell Cell and Zinc Solution, 69.
Cartridge Firing by Electricity, 23.
Chrystal, Prof., Address to Mathematical Section of British Association at Aberdeen, 350, 394.
City and Guilds Institute (Leading Article), 293.
City and Guilds Institute Examinations, List of Successful Candidates, 262.
City and Guilds Institute Exam. Papers, 70, 86.
Civil Engineers' Institution (*see* SOCIETIES' MEETINGS).
Clark, J. W., Electrolytic Decomposition, 49.
Colour Mixtures, by Capt. Abney, 162.
Commutator, A Mercury Contact, by Prof. J. V. Jones, 370.
Companies in Liquidation, 234, 384, 478.
Compasses and Iron Ships, 457.
Compound Winding Dispute (Leading Article), 422.
Conductors (*see* also MAINS).
Conductors, Determination of Currents and Resistance in a Network of, 448, 463, 483.
Conductivity of Metals and their Alloys, by L. Weiller, 435, 455.
Contact Electricity, by J. T. Bottomley, 377.
Conversazione at Finsbury College, 201.

COMPANIES' MEETINGS :—
  Anglo-American Brush, 244.
  Anglo-American Telegraph, 204, 239.
  Anglo-Continental Telephone, 478.
  Brazilian Submarine Telegraph, 86, 462, 477.
  Consolidated Telephone, 36, 50.
  Cuba Submarine, 204, 223.
  Direct United States Cable, 184, 219.
  Direct Spanish Telegraph, 462, 489.
  Eastern Extension, &c., Telegraph, 490.
  Eastern Telegraph, 164, 183, 202.
  Edison and Swan, 242.
  Electric News Telegraph, 384.
  Electric Sun Lamp, 333, 478.
  Electro-Amalgamator, 284.
  Globe Telegraph, 221.
  Great Northern Telegraph, 15.
  Hammond, 107.
  India Rubber, Gutta Percha, &c., 204.
  Jarman Electrical, 478.
  London Platino-Brazilian Telegraph, 14.
  National Telephone, 263.
  Provincial Brush, 87, 384.
  Pyramid Electric Light, 334.
  Railway and Electric Appliances, 223.
  South Eastern Brush, 68.
COMPANIES' MEETINGS (*continued*) :
  South of England Telephone, 51.
  Submarine Cables Trust, 15.
  Submarine Telegraph, 224, 242.
  United Telephone, 126.
  West Coast of America Telegraph, 108, 126.
  West India and Panama Telegraph, 16, 35.

CORRESPONDENCE :—
  Armature Winding, 81, 96.
  Baines, A. E., Electrical Condition of the Human Body, 376.
  Battery, Primary, A Useful Bichromate, 454, 472.
  Battery, Primary, Kauffer and Goldner's, 273.
  Batteries, Secondary, 119, 136, 157, 175, 293, 312, 329.
  Batteries, Secondary, Equalising the Charge of, 293, 312, 329.
  Bernstein, A., Incandescent Lamps, 471.
  Bichromate Battery, A Useful, 454, 472.
  Bottomley, W., jun, Non-magnetic Steel, 454.
  British Association, Sir L. Playfair's Address to, 376.
  Cable, Localising Earth Fault in, 195.
  Candle-power, Nominal, 120.
  Clark, Latimer, Nomenclature, 60.
  Clark, Latimer, The Pneumatic System, 395.
  Colliery Explosions, 159.
  Compasses and Ship Lighting, 472.
  Contact Pieces, 61.
  Copper *v.* Iron Wires, 454.
  Corrections, 177, 235, 253, 329.
  Current Induction, A Phenomenon of, 395, 413, 433, 453, 472, 484, 486.
  Day, R. E., Selenium Photometer, 396.
  Differences, 433.
  Drake, B., Secondary Batteries, 312.
  Dynamos, Armature Winding, 81, 96.
  Edison's Latest Invention, 96.
  Electric Lighting :—
    and Compasses on Ships, 472.
    Contract Jobbery, 155.
    Greatest Distance Current has been Transmitted for, 81, 97.
    for Liége, 159.
    in Milan, 45.
    for Mines and Houses, 158.
  Electrical Condition *v.* Recent Science, 9, 27, 46.
  Electrical Experiments, New, 45.
  Electrical Nomenclature, 60.
  Engine Governor, Richardson's, 253.
  Exhibitors at the Inventories, 176, 195, 213.
  Facsimile Telegraphy, 353.
  Fault in Cable, Localisation of, 195.
  Faure, C. A., Secondary Batteries, 157.
  FitzGerald, D. G., Kauffer and Goldner's Battery, 273.
  FitzGerald, D. G., Secondary Batteries, 136, 175.
  Fleming, J. A., Secondary Generators, 375.
  Galvanometer Readings, Unexpected Source of Error in, 121.
  Garratt, A. V., Kauffer and Goldner's Battery, 453.
  Gold Ores, Treatment of, 139.
  Governor, Richardson's, 253.
  Grundy, A., Life of Incandescent Lamps, 329.
  Heaviside, O., Electrostatic Capacity of Overground Wires, 375.
  Heaviside, O., Ideas, Words, &c., 311.
  Heaviside, O., Resistance of Voltaic Cells, 294.
  Hedges, K., Double-pole Switches, 312.
  Higgins, F., Copper *v.* Iron Wires, 454.
  Howard, F. G., Secondary Batteries, 136.
  Human Body, Electrical Condition of, 376.
  Ideas, Words, and Symbols, 311.

CORRESPONDENCE *(continued)*:
Incandescent Lamps, Life of, 329, 353, 376, 433.
Incandescent Lamps of Low Resistance, 471.
Induction—Copper *v.* Iron Wires, 454.
Induction, Current, a Phenomenon of, 395, 413, 433, 453, 472, 484, 486.
Information Wanted, &c., Hungarian Invention, 473.
Inventories Exhibitors at, 176, 195, 213.
Jamieson, A., Localising Fault in Cable, 195.
Johnstone, J., New Electrical Experiments, 45.
Kapp, G., Armature Winding, 96.
Kauffer and Goldner's Battery, 273, 453.
Mathematics, Blind, 61, 81, 121 (*see* also OHM's LAW).
More Light, 155.
Munro, J. M. M., New Testing Instrument, 329.
Munro, J. M. M., Unexpected Source of Error in Galvanometer Readings, 121.
Nomenclature, Electrical, 60, 311.
Nominal Candle-power, 120.
Ohm's Law and Potential Difference, 139, 157.
Philadelphia Exhibition, Report on Arc Lamps at, 120.
Photography and Electrical Measurements, 81.
Playfair, Sir Lyon, His Address to the B.A., 376.
Pneumatic System, The, 395.
Potential Difference (*see* OHM's LAW).
Pulley, New, for Dynamos, 329.
Reckenzaun, A., Secondary Batteries, 119.
Richardson's Governor, 253.
Salomons, Sir D., Application of Photography to Electrical Measurements, 81.
Salomons, Sir D., Equalising the Charge of Cells, 293, 329.
Secondary Generators, 375.
Selenium Photometer, 396.
Seleno-differential Recorder, 273.
Sellon, J. S., Secondary Batteries, 119.
Ship Lighting and Compasses, 472.
Sixpenny Telegrams, 195.
Smit, W., New Pulley for Dynamos, 329.
Smith, R. A., Ship Lighting and Compasses, 472.
Smith, Willoughby, Edison's Latest Invention, 96.
Sprague, J. T., Phenomenon of Current Induction, 413, 453.
Steel, Non-Magnetic, 454.
Swinburne, J., Secondary Batteries, 157.
Switches, Double-pole, 273, 312, 353.
Taund-Szyll, Von, Seleno-differential Recorder, 273.
Telephone in Cintra, 413, 433.
Telephone Wires and Rockets, 413, 433.
Testing Instrument, New, 312, 329.
Trains, Telegraphing between, 96.
Tribe, A., Secondary Batteries, 157.
Trotter, A. P., Nominal Candle-power, 120.
Vacuum Tubes, New Experiments with, 45.
Verity, J. B., Double-pole Switches, 273, 353.
Volk, Magnus, Testing Instrument, 312.
Voltaic Cells, Resistance of, 294.
Von Taund-Szyll (*see* TAUND-SZYLL).
Walker, S. F., Electric Lighting for Mines, 158.

Wilkinson, H. D., Blind Mathematics, 81, 121.
Wilkinson, H. D., Ohm's Law, 157.
Williams, E. A., Blind Mathematics, 61, 96.
Williams, E. A., Ohm's Law, 139.
Williams, E. A., Phenomenon of Current Induction, 395, 433, 453, 472.
Wires, Overground, Electrostatic Capacity of, 375.
Yorke, R. F., Bichromate Batteries, 472.

Correspondents, Answers to, 8, 156, 329.
Crawley, C. W. S., and Hawes, F.B.O., Recording Variations of a Current, 46, 63.
Current, Recording Variations of, by Crawley and Hawes, 46, 63.
Currents Alternating, by T. H. Blakesley, 22, 58, 114, 154, 390.
Currents, Peculiar Chemico-electric, by Dr. Gore, 199.
Currents and Resistance in a Network of Conductors, Determination of, 448, 468.

D

Daniell's Battery, a Modification of, by J. J. Coleman, 410.
Daniell's Cell, Relation between E.M.F. of, and Zinc Solution, by H. S. Carhart, 69.
Daniell's Cell, Standard form of, by Dr. Fleming, 161, 232, 255.

DEATHS:—
Heraghty, G. J., 9.
Jenkin, Prof. Fleeming, 97.
Muirhead, John, 393.

Décharme, C., Imitation of Electric Phenomena, 66, 95, 116.
Determination of Currents and Resistance in a Network of Conductors, 448, 468, 483.
Diamond Coal, 233.
Dinner Given by Cyrus Field, 238.
Dinner Given by Messrs. Paxman, 414.
Direct U.S. Cable Company *v.* Muirhead, 33.
Distribution of Electricity:—
Cantor Lectures, by Prof. G. Forbes, 414, 440, 457, 475, 486.
The Grouping System, by W. H. Snell, 196, 211 (*see* also MAINS).
An Unnoticed Danger in Apparatus for, by J. Hopkinson, 318.
Domestic Lighting, by W. H. Preece, 379.
Dumb-bell, Electric, 122.
Dynamos:—
Best Form of, by A. E. Sperry, 457.
Compound Winding Dispute (Leading Article), 432.
Design and Construction of, by G. Kapp, 23, 190, 250.
Regulation of, by W. B. Esson, 59, 82.
the Tecnomasio, 172.
Theory of, 210.
(*see* also EXHIBITION RECORD.)

E

Earth, Partial, in Cable, Localisation of, by J. Anderson and A. E. Kennelly, 177.
Earth's Magnetic Field, Intensity of H., by T. Gray, 433.
Education and Examination (Leading Article), 394.
Edward's Trade Mark Case, 219.
Electric Lighting:—
at Ashton Court, 281.
and Atmospheric Absorption, by Prof. W. G. Adams, 362, 381.
at Bucharest National Theatre, 140.
Domestic, by W. H. Preece, 379.
Examination Paper of City and Guilds Institute on, 70.
Experiments on the "Colossus," 71.
at Forth Bridge Works, by J. N. Shoolbred, 354.
at Greenock, 381.
at Her Majesty's Theatre, 272,
Installations, Recent (Leading Article), 80.
for Lighthouses, 297, 310.
in London, 43.
in Luxemburg Prison, 200.
Private Installations, by R. H. C. Neville, 235, 252.
by Means of Secondary Batteries, 181.
on Ships, by W. H. Snell, 275.
at Sir S. P. Grant's, Rothiemurhous, 473.
and Vegation, 200.
Electric Phenomena Imitated by Liquids, by C. Décharme, 66, 95, 116.
Electrical Engineering—A Lament, 474.
Electrical Instrument Making, Examination Paper of City and Guilds Institute, 86.
Electrical Prospects and the Crisis (Leading Article), 138.
Electricity:—
Distribution of—Cantor Lectures—by Prof. G. Forbes, 414, 440, 457, 475, 486.
Distribution of, the Grouping System, by W. H. Snell, 196, 211 (*see* also MAINS).
Distribution of, An Unnoticed Danger, by J. Hopkinson, 318.
and Magnetism, Mistakes in, by G. W. von Tunzelmann, 94.
as a Reviving Agent, 137.
Sources of, by Prof. Tyndall, 68.
Electrolier, Grundy and Ready's, 182.
Electrolytic Decomposition, by J. W. Clark, 49.
Electro-magnetic Induction, by O. Heaviside, 6, 78, 134, 170, 230, 270, 290, 306, 408.
Electro-magnetic Rotation of Electrolytes, Apparatus for Showing, by Dr. G. Gore, 215.
Electromotive Force of the Retina, 175.
Electromotive Force, Seat of, in a Voltaic Cell, by O. J. Lodge, 11, 27, 47.
Electromotive Forces in a Voltaic Cell, by O. J. Lodge, 437.
Electromotive Forces, Seat of, in a Voltaic Cell, by J. Hopkinson, 460.
Electro-optic Action of a Charged Franklin's Plate, by J. Kerr, 410.
Elwell, J. B., Thunderstorm at Albrighton, 434.
Engine Indicator, Steam, 9, 307.
Engines, Steam, at the Inventories (Leading Article), 485.
Errata, 431 (*see* also CORRECTIONS under CORRESPONDENCE).
Esson, W. B., Regulation of Dynamos, 59, 82.
Exhibition, the Inventions, Awards at, 261.
Exhibition at Philadelphia;—
Report on Underground Conduits shown at, 13, 33.
Report on Lamps shown at, 104.
Report on Carbons shown at, 124, 162.

The Exhibition Record, The Inventions (*see* SUPPLEMENTS of May 15, 29, June 12, July 10, 31, Aug. 28, Oct. 2, 30, Nov. 7).

[Note.—The paging given below is that of the Supplement.]

Allen's Engine, 23.
Andrew's Dynamo and Lamp, 33.
Bayley and Son's Exhibits, 10.
Browett, Lindley, and Co.'s Exhibits, 12.
Callender Company's Exhibits, 16.
Davey's Motor, 12.
Dynamos, by W. M. Mordey, 13, 21, 29.
Elwell-Parker Dynamo, 37.
Faraday's Exhibits, 7.
Forbes's Nonpolar Dynamo, 25.
Fountains, The, 28.
Garden Illuminations, 28.
Globe Electrical Company's Exhibits, 40.
Henley's Exhibits, 16.
Holmes and Co.'s ditto, 10.
Joel's Engine Dynamo, 5.
Kapp's Dynamos, 23.
Jones' Dynamo, 38.
Muirhead's Exhibits, 40.
Paterson and Cooper's Exhibits, 35.
Phœnix Dynamo, 35.
Pilsen Company's Exhibits, 11.
Robey's Engines, 14.
Scott and Company's Exhibits, 11.
Swan's Exhibits, 7.
Thomson, Dowsing, and Rew's Exhibits, 16.
Thomson-Houston System, 17, 21.
Trouvé's Exhibits, 9.

The EXHIBITION RECORD *forms a complete section, and will be continued from time to time.*

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XV. FRIDAY, MAY 15, 1885. Price 4d.

NOTES.

The Hipp Microphone.—A lengthy description of the Hipp microphone appears in the *Schweizerische Bauzeitung.*

Notices of Interruption.—Telegraphic communication with Venezuela is interrupted. The cable between Maranham and Para is interrupted.

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 8th inst. amounted to £3,115.

The Telephone in Spain.—Telephonic communication is about to be established between the Palace of the Mayor and the Hôtel de Ville at Barcelona.

The Eastern Telegraph Company.—This company notify the opening of a new branch West-End Station at 42, Parliament-street, Westminster.

Inventors' Institute, Lonsdale Chambers, Chancery-lane.—On Monday, 28th May, at 8 p.m., a Paper will be read "On Electric Tram Cars," by A. Reckenzaun, Esq.

An Electrical Sewing Machine.—The *Moniteur Industriel* announces the invention of an electrical sewing machine, in which the different parts are moved by electro-magnets.

The Telegraph to Merv.—The Tirpul correspondent of the *Daily Telegraph* is informed that the telegraph is completed to Sarakhs, and a branch is being laid from Kakraha to Merv.

The Electric Light in Milan.—Among projected installations we notice that the Ospedale Maggiore, the Palazzo, Marino, and the Galleria Vitt. Em. in Milan are to be lighted electrically.

Opening of a New Station in China.—The Eastern Telegraph Company notify the opening of a new telegraph station in China—Yamchow—the rate from Great Britain being 10s. per word.

The International Convention.—The International Convention for the protection of submarine telegraph cables, which was signed at Paris on March 14th, was issued on Saturday last as a Parliamentary paper.

The Force Exerted by an Electric Spark.—M. Gaston Planté has almost terminated a series of experiments demonstrating the nature of the mechanical force that the spark of a rheostatic machine is able to exercise.

The Electric Light in Berlin.—The Royal Library at Berlin is to be experimentally lighted by electricity, and kept open a couple of hours later nightly, to enable the public to form an opinion upon the innovation.

The Electric Light at the Opera House, Paris.—The electric light in the body of the hall at the Opera, Paris, which failed on a previous occasion, gave great satisfaction at the second performance of "Tabarin."

The Telephone in Marseilles.—The subscribers to the telephone exchange in Marseilles are now permitted to both send and receive their telegrams by telephone upon paying a supplementary tax of 50 francs per annum.

Change of Address.—The address of the Indo-European Telegraph Company in Manchester is changed to 60, Spring-gardens. Offices have also been opened at 9, East India-avenue, and at 10 and 11, Mincing-lane, E.C.

Development of Electricity in the Filtration of Mercury.—In filtering mercury by means of the Pfaundler apparatus M. J. Dechant has recognised that a sensible quantity of electricity is developed during the operation.

Dynamos for the War Department.—The Anglo-American Brush Electric Light Corporation has received orders to supply, by the first week in July, 23 of their compound wound slow-speed dynamos for use in submarine mining.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 8th May were £2,456, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Temporary Electric Lighting.—On the occasion of a dance given by Lady Mills, on the 6th inst., the reception and other rooms were lit by the electric light. The installation was carried out for Mr. F. G. Howard by the Electrical Power Storage Company.

The Electric Light in Ohio.—At Dayton, in the State of Ohio, in America, there are 515 subscribers to the telephone out of 50,000 inhabitants. The town is lighted by 200 Fuller arc lamps, and it is also proposed to construct a central station for incandescent lighting.

The Dream of Paris.—The discussion upon the project of MM. Bourdais and Sebillot of illuminating the whole world by means of 500,000 billions of arc lamps on the top of a big stick in Paris commenced last week at a meeting of the members of the Société des Ingénieurs Civils.

Electric Lighting at a Ball.—On the 6th inst. the Electrical Power Storage Company carried out a large temporary installation for Mr. S. Montague, of 12, Kensington Palace-gardens, the whole of the reception rooms, conservatories, and passages being lit by over 120 lamps of 20 candle-power.

Influence of Light on the Electrical Resistance of Metals.—From a series of elaborate experiments made in the Yale College Laboratory on plates of platinum, gold, and silver, it has been concluded that if light causes any diminu-

Digitized by Google

tion in the electrical resistance of metals, it probably does not exceed a few thousandths of 1 per cent.

THE LATE SIR W. SIEMENS.—A lecture was recently delivered in Firth College, under the auspices of the Literary and Philosophical Society, in reference to the career and inventions of the late Sir Charles William Siemens, by Mr. W. Carpenter, B.A., B.Sc., &c., Manager of the School of Submarine Telegraphy and Electrical Engineering, London.

TELEGRAMS.—Mr. Lefevre informed Mr. W. Lawrence that there was no intention to make any change in the present practice with regard to telegrams, which was that, when the message could not be delivered, an official message was sent to the office of origin ; and if the sender was not within the limits of that delivery, intimation was sent to him by first post.

ELECTRICITY AT LIMOGES.—The manufacturers and tradesmen of Limoges have nominated a committee to report upon the electric lighting of the town. The principal points to be established will be the price of each lamp of 10 candles according to whether 1,000, 2,000, or 3,000 lamps are used, and the nature of the guarantee for the regularity and fixity of the light.

PERSONAL.—At a special meeting of the Salford School Board held recently for the purpose of electing a member in the place of Alderman F. H. Walmsley, who has resigned, Mr. Walter T. Glover, electric cable manufacturer, Salford, was elected a member of the Board, and was placed upon the several committees of which Mr. Walmsley had been a member.

COMBINED ARC AND INCANDESCENT LIGHTING.—Some interesting experiments were recently made on an American steamboat in operating arc and incandescent lights from the same dynamo. An improved Edison dynamo was employed and resistance coils introduced to adjust the tension for the two systems. The experiments were said to have been successful.

ELECTRIC LIGHTING OF A FROZEN MEAT STORE.—The contract for the electric lighting of Messrs. Bell and Son's new premises in Charterhouse-street has been given to the Electrical Power Storage Company, of 4, Great Winchester-street. It will doubtless be remembered that this firm lit some time back the cold meat stores belonging to the East and West India Dock Company.

ELECTRICITY AND PHYLLOXERA. — A contemporary is informed that a curious phenomenon is reported from some of the Malaga vineyards, where plants, attacked by the phylloxera and given up as practically dead, have begun to show marked symptoms of vitality, due, it is believed, to the destruction of the insects by gases or "electrical conditions," consequent on the recent earthquakes in the locality.

THE TELEPHONE IN GERMANY.—The progress realised in Germany by the telephone during the last ten months of the year 1884 is as follows :—Additional exchanges 9, additional subscribers 1,953, increased mileage of wire 2,095. The principal exchanges are those of Berlin with 2,178 subscribers, Hamburg with 1,224 subscribers, Frankfort-on-Main with 366, Dresden with 354, Leipzig with 321, Mannheim 254, Cologne 223, Stettin 222, and Magdebourg 194.

THE BICHROMATE CELL.—M. Radiguet has invented a new form of the bichromate of potash cell, which permits of the zincs being lifted out and the two solutions of the battery isolated from each other by a single and simple operation. The Carpentier cell, working with a single solution of bichromate and generating a constant current of 1·5 ampere, is giving great satisfaction. This cell, as is well known, owes its constancy to the fact that circulation of the liquid is kept up.

THE INVENTORIES.—In connection with the lighting of the subway from the railway station to the Inventions Exhibition, we are informed that Messrs. Goolden and Trotter have been temporarily supplying the current to the batteries of the Consolidated Company, whose dynamo was not ready for running. The current has been generated by their Halifax machine, which, being run at 12 per cent. above its normal capacity for 16 hours daily, has had an excellent opportunity of proving its capabilities.

CONTRACT.—The contract for the sup ply of telegraph instruments and batteries, for the next twelve months, to the Manchester, Sheffield and Lincolnshire Railway Company, has been secured by Messrs. Blakey, Emmott and Co., of the Northern Telegraph Works, Halifax. This firm have just issued an illustrated catalogue in three parts—Part I. containing list of railway signal apparatus, resistance coils, and general testing apparatus ; Part II. electric bells, &c. ; and Part III. electric light machinery.

THE VOLUNTEER TELEGRAPHISTS.—One of the volunteer telegraphists for the Soudan, writing of Alexandria, says :—"The houses, as a rule, are very inferior from an architectural point of view ; but the buildings of the General Bank of Egypt, the Post Office, the office of the Eastern Telegraph Company, and others are magnificent, both externally and internally. The Soldiers' and Sailors' Home, too, is worth mentioning. There is at present an addition being made to it, and when completed it will be a grand place indeed."

THE ZANZIBAR-MOZAMBIQUE CABLE.—The duplication of this cable, which is part of the Eastern and South African Company's system, is being actively proceeded with, the ss. "Chiltern" having already arrived on the ground. It has been ascertained that the last fault in this section was due to one of the submarine landslips so common along the East African coast. It will be remembered by many of our readers that two of the three faults in the Mozambique-Delagoa Bay cable were due to the same cause. In order to ensure greater safety the new section will be laid in deep water, at a considerable distance from the dangerous locality.

CURE OF WRITER'S CRAMP.—A very interesting article on this subject by A. de Watteville, M.A., M.D., B.Sc., appears in a recent number of the *Lancet*, in which the author describes some very remarkable results obtained by Mr. Wolff, of Upper Berkeley-street, London, by a combined application of massage, gymnastics, and caligraphic exercises. A very singular cure of writer's cramp in the case of a Liverpool merchant, and another in the case of a lady, are described at length, and in each instance the aggravated character of the disorder and the progress of cure are illustrated by specimens of handwriting.

OVERHEAD WIRES AT BRIGHTON.—After having for a long time declined to allow the Post Office to erect overhead wires in the streets, the Brighton Town Council have given permission to the department to do so. The present permission relates to the crossing of five streets, and the municipal authority stipulate that the wires shall be placed at a distance of not less than 40ft. from the road at the lowest part of the span, and that in the event of any improved method coming into general use for fixing telegraph or telephone wires, for strengthening the lines, or allowing them to be worked underground, or lessening the danger to the public, the Post Office shall adopt it, after six months' notice from the Corporation.

Digitized by Google

A SAVING CLAUSE.—In a lighting contract for the Municipality of Liége, the Birmingham of Belgium, it is stipulated that if, in consequence of a new discovery, or an improvement introduced into any system of lighting already known, there should be established by regular concessions in one or more towns of Belgium, Holland, France, England or Germany, having a population of not less than 50,000, a system of lighting both for the public and for private individuals, as good and more economical than gas, and that this superiority, equal to at least 15 per cent., be shown by a trial of three years, the Municipality will have the right, subject to the conditions stated, of adopting the new system of illumination.

LARGE ORDER FOR DYNAMOS FOR THE NAVY.—Twenty of the picket boats which are building for the Admiralty are each to be fitted with engines and dynamos for use with search light projectors. These dynamos and engines have been ordered from the Anglo-American Brush Electric Light Corporation, who have also received instructions to supply similar apparatus for H.M. gunboats "Tees," "Spey," "Tay," "Slaney," "Medena," and "Medway," and for H.M. tugboats "Woodcock" and "Magnet." The dynamos for the picket boats, the tug boats, and three of the gunboats are to be coupled to Willans engines, and the remaining three dynamos for the gunboats to engines manufactured by Messrs Goodfellow and Matthews.

THE TELEGRAPH IN SENEGAL.—The French Colonial Minister is actively occupied on a scheme for the extension of the telegraphic system of Senegal. A new line was opened on the 9th of last February of a length of seventy-five kilometres, between Rufêsque and Joal, the construction of which, despite the difficulties presented by numerous dense forests and rivers, occupied only thirty-three days. We are informed that for the new service it has been decided to substitute the Leclanché form of battery for the Marié-Davy, wihch latter has been up to the present exclusively adopted in Senegal. This measure has been rendered necessary by the deterioration of the Marié-Davy battery under the influence of the constant variations of temperature in Senegal.

ROYAL METEOROLOGICAL SOCIETY.—An ordinary meeting of this society will be held by permission of the Council of the Institution of Civil Engineers at 25, Great George-street, Westminster, on Wednesday, the 20th inst., at 7 p.m., when the following papers will be read:—"The Temperature Zones of the Earth in Connection with its Biological Conditions," by Dr. W. Köppen, Hon.Mem.R.Met.Soc.; "Velocities of Winds and their Measurement," by Lieut.-Colonel H. S. Knight, F.R.Met.Soc., F.R.A.S.; "Note on Mr. C. Harding's Paper on Wind Velocities," by Dr. W. Köppen, Hon.Mem.R.Met.Soc.; "Note on a Peculiar Form of Auroral Cloud Seen in Northamptonshire, 1st March, 1885," by Rev. James Davis (communicated by the President).

ELECTRICAL HEADLIGHTS.—At the annual meeting of the shareholders of the American Electric Headlight Company, held at the Denison House, Indianapolis, on April 21, one of the directors stated that the company had passed the experimental stage. The plant they had now in use weighed about 400lb., and instead of running their engine 1,500 revolutions per minute, they had reduced the speed to 600. A year ago it was thought impossible to sell a full equipment for less than 800 dollars; the price now is 450 dollars. The company had patents covering nearly 300 claims in the United States, and controlled patents in seven foreign countries. The lamp they were now using is the invention of George Pyle, and is the only lamp ever made that is electrically governed, all springs, weights, dash pots, &c., having been dispensed with.

NEW TELEGRAPH STEAMER.—Messrs. R. Napier and Son, Govan, have been successful in their negotiations with the Eastern Extension, Australasia, and China Telegraph Company in reference to the construction of a telegraph ship to take the place of the "Magneta," lost a few weeks ago in the Bay of Biscay. The Messrs. Napier have received orders to proceed at once with the construction of a new vessel, which will be of similar dimensions to the "Magneta"—850 tons, 230ft. long, 32ft. in breadth, and 24ft. deep, and will be supplied with compound engines of 1,400 horse-power, to obtain a speed of 12½ knots. The new vessel, like her predecessor, is intended, and will be specially fitted up, for laying, picking-up, and repairing the submarine cables of the telegraph company for which she is to be built. The new vessel will be built of Scotch steel.

ELECTRO-CHEMICAL EQUIVALENT OF SILVER.—An account has been given of experiments made with a view of determining the electro-chemical equivalent of silver in terms of practical units. The final number expressed in C. G. S. units is $1{\cdot}118 \times 10^{-2}$, a value in accordance with that determined by Kohlrausch; thus in practical units the quantity of silver deposited per ampere per hour is 4·0246 grams. With a view of obtaining a convenient standard of E.M.F., a detailed examination of Clark's cells, which possess the advantage of standing ready for use, and not polarising greatly on the passage of small currents, has been made. The value for the E.M.F., that of the B. A. unit, being 0·9867 ohm, is equal to 1·435 volt, with an extreme range of $\frac{1}{1000}$ during six months, although about ten days are required before the cell reaches its permanent condition.

OVER STUDY.—An inquest was held at Plumstead on Saturday, before Mr. Carttar, coroner, on the body of Walter Edward Burrell, aged 19, who committed suicide at 6, Burrage-road, Plumstead, by shooting himself with a revolver. The father stated that the deceased had been employed by the Brush Electric Light Company, and had of late been studying electricity and kindred subjects, which had injured his health. He left the company and got employment in the Arsenal, but could not bear the noise of the machinery, and took his discharge. On Thursday night he shut himself in his bed room, and a few minutes later the report of firearms was heard, followed by a heavy fall, the young man having shot himself with a five-chambered revolver in the right temple. The jury returned a verdict that "Deceased committed suicide while labouring under temporary insanity induced by over-pressure."

THE NEW HOTEL METROPOLE.—We are informed that the whole of the electroliers for the new Hotel Métropole, numbering between two and three hundred in all, and which are of the most elaborate character in the French and Italian renaissance styles, have been designed, the patterns made, and the whole manufactured in the short space of three weeks at the works of Messrs. B. Verity and Sons, in Covent garden. In the hotel, which is one of the largest in Europe, the electric light is at present used only as far up as the second floor; but when the number of large reception rooms, and the grand corridors, and the exceptionally high-class character of the electroliers is taken into consideration, the work turned out reflects great credit upon everybody concerned. At the opening of the hotel, on Monday next, when a grand military concert will be given in aid of the Egyptian War Fund, the Prince and Princess of Wales will be present.

THE LAROCHELLE PORTABLE BATTERY.—The title of M. Larochelle's battery has been badly chosen in that its dimensions and weight are sufficiently great to render the word "portable" as applied to it somewhat ridiculous. In a pattern lately shown the battery was contained in a vase of ebonite divided into eight compartments, each containing two small rods of carbon and one of zinc. It is said that eight cells connected in series are capable of furnishing current for 64 candle hours. The constancy of the light is said to be due to the composition of the solution, which composition the inventor has kept secret. A contemporary is informed that the liquid is corrosive, and that india rubber gloves have to be worn by those who have the manipulation of the battery. The zincs and carbons are fixed to a disc, and so arranged that accordingly as they are more or less immersed in the liquid, the light emitted is more or less intense. When not in action they are lifted out of the solution by means of a key similar to that of the ordinary oil lamp.

THE SUBMARINE TELEGRAPH CABLES BILL.—In the House of Lords on Monday last Lord Sudeley moved the second reading of this Bill, which was founded upon a convention which was agreed upon with other Powers in March last year. The Earl of Camperdown was understood to say that he would be glad to hear what the other companies would do in carrying out the same convention. Supposing there were an infraction of the convention, would the other countries take any notice of it? In the event of a war, for instance, what penalty would be inflicted upon the subject of the country who damaged the cable? He hoped that on a future stage of the Bill his noble friend would make a full statement upon the subject of the Bill. The noble earl subsequently added that this was a very important matter, as the time for the ratification of the convention had lapsed, and he would be glad to know what had been done in regard to it. After a few words from Lord Sudeley, referring to Clauses 12 and 17 of the Bill, the Bill was read a second time.

THE ELECTRIC LIGHT AT JARROW.—The General Steam Navigation Company's steamboat "Albatross," since hired by the Government, has sustained an amount of damage to her keel, and likewise to the lower part of her stem. The owners arranged with a Jarrow firm to complete the repairs within seven or eight days, and Messrs. Clarke, Chapman, and Co., of Gateshead, were instructed to light up the dock where necessary with the electric light. On the following night workmen employed by that firm arrived at the yard with the necessary engine to produce the motive power, and with the lamps, which were of various descriptions. In less than three hours after arrival a current of electricity was forced through the wires attached to the lamps erected. The engine, which is very small, is one of the first of a new pattern at present in use, one of the others being in the possession of the Tyne General Navigation Company. It is scarcely necessary to say that the work for the Navigation Company could not have been done in this instance had it not been for the judicious use of the electric light.

FREEMASONRY.—On Thursday, the 6th inst., the R. W. Provincial Grand Master of Middlesex, Brother Sir Francis Burdett, Bart., P.G.W., consecrated the "Electric" Lodge, No. 2,087, at Hampton Court, of which Brother Edward B. Bright was designated the first master, Brother W. H. Preece Senior Warden, and Brother J. Hookey Junior Warden. The P.G.M. was supported by an influential gathering of members of the craft, among whom were Sir Charles T. Bright, P.D.G.M. Middlesex; Colonel Shadwell Clerke, Grand Secretary; the Deputy Provincial G. M. Dr. Ramsay, C. E. Spagnoletti, &c. The ceremony of constitution was very impressively conducted by the P.G.M., who congratulated the new lodge on having started under such favourable auspices. The Deputy P.G.M., Brother Raymond Thrupp, installed Brother Edward Bright as Master; and the following officers were appointed:—Wardens: W. H. Preece and J. Hookey. Treasurer: Major W. E. Williams. Secretary: George Gregory. Deacons: T. Barlow and H. C. Hart, I. G. T. Fletcher. Stewards: D. Lumsden and W. R. Culley. Three candidates were proposed for initiation and 21 as joining members. At the banquet which followed the usual loyal and masonic toasts were duly honoured. The meetings will take place on the fourth Saturday in May, June, and September, at the Mitre Hotel.

THE BOYDEN PREMIUM.—Uriah A. Boyden, Esq., of Boston, Mass., has deposited with the Franklin Institute the sum of 1,000dols., to be awarded as a premium to "any resident of North America who shall determine by experiment whether all rays of light, and other physical rays, are or are not transmitted with the same velocity." The following conditions have been established for the award of this premium: 1. Any resident of North America, or of the West India Islands, may be a competitor for the premium, the southern boundary of Mexico being considered as the southern limit of North America. 2. Each competitor must transmit to the secretary of the Franklin Institute a memoir, describing in detail the apparatus, the mode of experimenting, and the results; and all memoirs received by him before the 1st of January, 1886, will, as soon as possible after this date, be transmitted to the committee of judges. The board of managers of the Franklin Institute shall, before the 1st of January, 1886, select three citizens of the United States of competent scientific ability, to whom the memoir shall be referred; and the said judges shall examine the memoirs and report to the Franklin Institute whether, in their opinion, and, if so, which of their memoirs is worthy of the premium. And, on their report, the Franklin Institute shall decide whether the premium shall be awarded as recommended by the judges.

UNDERGROUND WIRES IN CHICAGO.—An American Contemporary says that this City is far ahead of New York in the work of removing the overhead telegraph nuisance, and it is likely that all the wires in the Garden City will soon be laid underground. The following figures approximate the miles of wire already placed beneath the streets of that city:—

Bankers' and Merchants' Telegraph Company...	400
Postal Telegraph Company	180
Chicago Telephone Company.....	28
Western Indiana Railroad Company.....	50
City Fire-Alarm Telegraph	60
Total.....	718

As soon as possible the Western Union Company will add 500 miles to this, and the Baltimore and Ohio Company 250 miles. This will make a grand total of 1,468 miles. Electric light wires are rigidly confined to buildings and personal premises, and the companies are forbidden to suspend their wires on poles or otherwise. The work of placing the fire alarm system under ground is being pushed as fast as possible. It is expected that it will take ten years to complete the work, and it will cost 500,000 dollars. Of this sum 50,000 dollars will be spent annually. The conduits are being constructed of a size and solidity which will insure their lasting. A mile and a half of these conduits have been completed so far.

THE TELEPHONE AT INVERNESS.—The district manager of the National Telephone Company at Inverness supplies us with the following particulars regarding the work of the past four

Digitized by Google

months :—"It is scarcely four months since we began our exchange in Inverness, and to the list issued at that time (19th January, 1885), we have since added eleven new names, and are at present negotiating with the estates of Dochfour and Aldourie, and also for the establishing of a call office at Dochgarroch Locks, for the convenience of the steamer passengers and others resident in that district. By means of this office tourists may secure accommodation at the hotels they prefer, during the interval in which the steamer is going through the lock. The fee for speaking from Dochgarroch to Inverness will be the same as is at present charged in town, viz., 3d. for three minutes and 1d. for every minute additional. Since we opened we have taken an average of about 2,000 messages weekly, including 100 from call offices alone. That these call offices are being taken advantage of by the public there can be little doubt, as no less than 140 out of a total of 1,400 received have been paid for, representing an average of 10 per cent. There are at present about 60 subscribers in town, and each subscriber uses his telephone at least six times per day; thus, at the yearly rental of £10, the cost of each message is on an average about 1⅓d. This includes question and answer. It will also be of interest to know that the company have now over 60 instruments in operation and 26 miles of wire, there being a telephone to every 300 persons in Inverness."

Electrical Transmission of Power at Bienne, in Switzerland.—There are two turbines, one working at high pressure and the other at low pressure, placed at the village of Boujeon, at the falls of the River Suze. The high-pressure turbine has been in use for rather more than a year, to work a dynamo machine for the electrical transmission of power to two factories at Bienne. The total height of the fall is 177ft., and the quantity of water 330 gallons per second. The turbine, however, only utilises actually 157½ft. of the fall, and can take, when the guide blades are wide open, 88 gallons per second. The turbine is one of Girard's, with a horizontal axle, driving accumulator shaft by spur gearing. The generator is a Thury dynamo machine of the type H_2, compound wound, and is driven by a belt from the countershaft; it runs at a speed of 500 revolutions per minute, and gives an E.M.F. of 350 volts. The conductors consist of two copper wires 7mm. in diameter (about No. 2 B.W.G.), carried on telegraph posts and insulators. The motor is also a Thury machine of the H_2 type, compound wound. It runs at a speed of 400 revolutions per minute, with a difference of potential of about 300 volts at the terminals. The distance from the generator to the motor is about 1,367 yards, and the motor gives out from six to 18 horse-power, according to the exigencies of the work being done in the factories. Both ends of the line are protected by lightning conductors, a very necessary precaution in a district where thunderstorms are very prevalent. When starting the motor a resistance is at first switched into the circuit, but this is cut out by step as the machine starts. It is stated that a commercial efficiency of 70 per cent. has been obtained.

Pyro-electricity of the Topaz.—Friedel's observation that in topaz the principal axis of pyro-electricity is parallel with the edges of the prism has been confirmed. Many fragments show poles of the same sign at both ends, but in such cases the fragment can be cleaved into two parts, the bases of which will have opposite polarity. In one instance, one extremity of the fragment was bounded by the natural summit of the crystal, and the other extremity by a cleavage plane, and both ends showed negative electricity when cooled. When this fragment was cleaved at the middle, one half showed regular polarity, whilst the other half was still negative at both ends, but with different intensities. These results are explained by the existence of twinning parallel with the base of the prism. With colourless rounded Brazilian topaz the pyroelectricity was much less marked, and with certain sections was almost imperceptible. Frequently both terminations have the same sign, but in many cases the removal of a very thin layer changes the sign of one termination, and produces fragments with regular polarity. Optical examination shows that the topaz crystals are not homogeneous, but in many cases can be separated into four distinct portions along the diagonals of the rhombic base. Generally, however, these four parts enclose an inner rhombic prism with regular extinction, and the crystal can consequently be split up into five distinct portions, which, however, are still not homogeneous. From some larger crystals in which the planes of twinning were very distinct homogeneous fragments have been obtained, which establish the existence of a horizontal axis of electricity, but the specimens were not sufficiently large for the exact direction of this axis to be determined. The existence of the horizontal axis was confirmed by the development of electricity under pressure.

Determination of the Ohm by the Damping Method.—With some few exceptions, the various methods for the determination of the ohm which were brought before the Paris Conference all gave values of the ohm greater than 1·06 metre of mercury 1 square millimetre in section, except the damping method, which has always led to lower values. M. Mascart has been led to investigate more closely the theory of this method, in order to see if this difference may he accounted for. Without following his mathematical reasoning it may be said that Mascart arrives at a formula which is that given by Maxwell, viz. :—

$$R = \frac{M^2 G^2}{2K(\epsilon - \epsilon_0)}\left(1 + \frac{2L}{R}\epsilon\right)$$

where R is the resistance of the coil, M the moment of the magnet, G the mean galvanometer constant, K the moment of inertia of the magnet, L the coefficient of self-induction. When the damping is considerable the duration of the oscillations cannot be determined directly by experiment, and it is more general to deduce it from the relative duration, when the coil is an open circuit, by the formula

$$\epsilon^2 + \gamma^2 = \epsilon_0^2 = n_0^2$$

But this formula is not strictly correct; in fact, the correction which ought to be introduced into the calculation of the resistance, in order to take into account the coefficient of self-induction, is half that which is usually taken by adopting the above formula. This correction is, however, not the only one which has to be taken into account, but there is a more important one. In actual experiment the induced currents are necessarily very powerful, in order that the damping may be appreciable. These induced currents produce a temporary magnetism in the bar in a transverse direction, which must be taken into account. The intensity of the temporary magnetism of the bar is proportional to the action of the current. This magnetism does not modify the fundamental equation so far as the induction is concerned, but the earth's action on the bar introduces a new couple of opposite sign to that due to the permanent magnetism, and the value of this new couple must be subtracted. The original hypothesis as to the smallness of the deflections, and the constancy of the galvanometer coefficient G, may still leave some doubt as to the degree of exactitude of the result; but at any rate the two corrections referred to both tend to increase the values of the unit of resistance hitherto arrived at by the method of damping.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 491, Vol. XIV.)

Electrostatic Energy. Closed Displacement.

In the theory of electrostatics a tube of displacement has a beginning and an end, at its beginning there being positive, at its end negative electrification. The terminations of the tubes are usually upon conducting surfaces; there may, however, be interior electrification in the dielectric, if so, it has got there by convection, or by disruption. Impressed force in the dielectric is not considered in the theory of electrostatics. But should there be any, there will usually be closed tubes of displacement without electrification, as well as terminated tubes, due to the presence of conductors; and should there be no conductors, the displacement set up by impressed force is wholly solenoidal. This will be briefly considered later. At present we take the case of closed displacement in a dielectric arising from electromagnetic induction. Conductors are temporarily excluded for simplicity. Let there be any state of electric displacement D and magnetic induction B in an infinitely extended dielectric, without impressed forces. A possible state of induction and displacement is meant, of course. For instance, set up any state of displacement by impressed force, which then remove, leaving the system to itself. E and H being the electric and magnetic forces at any moment, we have

$$B = \mu H, \qquad D = cE/4\pi; \quad . \quad . \quad . \quad . \quad (66)$$

μ being the permeability and c the specific capacity. The tubes of B are always closed. Those of D are also closed, if there be no bodily electrification. We cannot, therefore, express the electrostatic energy in terms of the scalar electric potential and the electrification. The appropriate form is in terms of the magnetic current and its vector potential.

Let Z be such that

$$-\operatorname{curl} Z = cE, \quad . \quad . \quad . \quad . \quad . \quad . \quad (67)$$

which is possibly because this is the general integral of $\operatorname{div} cE = 0$, expressing that the displacement is closed. Z is the vector potential of the magnetic current. It is given by

$$-Z = \Sigma \frac{\operatorname{curl} cE}{4\pi r}, \text{ or } = -\operatorname{curl} \Sigma \frac{cE}{4\pi r}, \quad . \quad . \quad . \quad . \quad (68)$$

by potential properties. Here r is the distance from the point where Z is reckoned of the element of the quantity summed up through all space. To Z, as given by (68), any polar term may be added without affecting (67); Z, after (68), being wholly solenoidal, like B and D. Since the second equation of induction is

$$-\operatorname{curl} E = \mu \dot{H} = 4\pi G, \quad . \quad . \quad . \quad . \quad . \quad . \quad (69)$$

G being the magnetic current, the equation of Z, by (67) and (69), is

$$\operatorname{curl} c^{-1} \operatorname{curl} Z = 4\pi G; \quad . \quad . \quad . \quad . \quad . \quad . \quad (70)$$

from which we see that when c is constant, we have

$$Z = c \Sigma \frac{G}{r}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (71)$$

verifying that Z is the vector potential of the magnetic current.

If U be the electric energy (energy of electric displacement), we have

$$U = \tfrac{1}{2} \Sigma ED = \tfrac{1}{2} \Sigma \frac{D}{\operatorname{curl}} \operatorname{curl} E = \tfrac{1}{2} \Sigma ZG, \quad . \quad . \quad (72)$$

by potential properties, and (67) and (69).

These may be instructively compared with the corresponding magnetic equations. If A be Maxwell's vector potential of the electric current we have

$$\operatorname{curl} A = B = \mu H, \quad . \quad . \quad . \quad . \quad . \quad (67a)$$

resulting from integrating $\operatorname{div} B = 0$. And the first equation of induction is

$$\operatorname{curl} H = c\dot{E} = 4\pi \Gamma, \quad . \quad . \quad . \quad . \quad (69a)$$

Γ being the electric current. So, T being the magnetic energy, we have

$$T = \tfrac{1}{2} \Sigma HB/4\pi = \tfrac{1}{2} \Sigma \frac{B}{\operatorname{curl}} \operatorname{curl} H/4\pi = \tfrac{1}{2} \Sigma A\Gamma, \quad (72a)$$

by (67a) and (69a). And, if μ be constant, we have

$$A = \mu \Sigma \frac{\Gamma}{r}. \quad . \quad . \quad . \quad . \quad . \quad (71a)$$

These four equations marked a correspond to the former equations with the same numbers. We have also

$$E = -\dot{A} - \nabla P, \quad . \quad . \quad . \quad . \quad . \quad (73a)$$

and, to correspond thereto,

$$H = -\dot{Z} - \nabla \Omega, \quad . \quad . \quad . \quad . \quad . \quad (73)$$

P being the scalar single valued electric potential, and Ω the scalar single valued magnetic potential. (73a) is Maxwell's equation. To prove (73), we may merely remark that by (69a) the magnetic force round a closed curve equals 4π times the electric current through the curve; and by (67) the same relation holds between $-Z$ and 4π times the displacement. Or, differentiate (67) to the time, and compare with (69a).

So far as the energy expressions in (72) and (72a) go, it does not matter whether Ω and P are counted or not, though they usually exist, especially if there are variations of permeability or capacity from place to place.

Other forms of U and T:—When A and Z are wholly solenoidal,

$$U = \Sigma \dot{A} c \dot{A}/8\pi - \tfrac{1}{2} \Sigma P\sigma$$

$$T = \Sigma \dot{Z} \mu \dot{Z}/8\pi - \tfrac{1}{2} \Sigma \Omega \rho$$

if $-4\pi\rho = \operatorname{div} \mu\dot{Z}$ and $-4\pi\sigma = \operatorname{div} c\dot{A}$; (73) and (73$a$) holding good. Here σ is imaginary electrification, and ρ imaginary magnetic matter, the first being where c and the second where μ varies.

Simple Example of Closed Displacement.

In this example there is a conductor in the field, but as, from symmetry, it will be obvious that the displacement is wholly closed, it will not matter. If an intrinsic magnet be at rest in a dielectric, there is no electric force, but merely a state of magnetic force. But if it be set in motion there is immediately a field of electric force set up as well, and of displacement and electric current due to changing displacement. Whether the displacement does not or does cause electrification will depend upon whether it is, at the surface of a conductor, wholly tangential or not, for it is the normal component that introduces surface electrification. Now, if a straight bar magnet of circular section be carried through the air parallel to its length, the lines of electric force are clearly circles about the line of motion, so that the displacement in the air is wholly closed. Or, let a uniformly intrinsically magnetised sphere move through a dielectric in the direction of its axis of magnetisation with constant velocity v small compared with that of the propagation of light, so that we may regard the sphere's field of magnetic force to be rigidly attached to it and move with it without change. A certain state of electric force in circles about the line of motion, the continuation both ways of the sphere's axis, is set up, changing at any *fixed* point continuously. But if we travel through the air with the sphere, the electric field is stationary. We may thus regard the magnet as carrying with it, in rigid connection, a certain constant electric field as well as its magnetic field. The first approximation to the solution, by far the most important part, is readily found.

Let M be the magnetic moment of the sphere, of radius a; z distance measured along the line of motion, from a fixed origin, of the centre of the sphere at time t; r the distance of any point, P, from the centre of the sphere, and θ the angle r makes with z. The magnetic potential at P is

$$\Omega = M\cos\theta/r^2.$$

Let v be the velocity of the sphere, then

$$z = z_1 - vt,$$

t being the time and z_1 constant.

Digitized by Google

This gives $d\Omega/dt = -vd\Omega/dz$;

so that the magnetic current at the point P is

$$G = \mu\dot{H}/4\pi = -\nabla\dot{\Omega}/4\pi = (v/4\pi)\nabla\frac{d\Omega}{dz};$$

or, using the above value of Ω,

$$G = (vM/4\pi)\nabla\{(1 - 3\cos^2\theta)/r^3\}, \quad . \quad . \quad . \quad (74)$$

the differentiation ∇ being conducted at P.

Calculate the total of G through the circle r, θ. This is, if $\omega = \cos\theta$,

$$\frac{vM}{4\pi}\int\int r^2 d\phi d\omega \frac{d}{dr}\frac{1 - 3\cos^2\theta}{r^3} = \frac{3vM}{2r^2}\omega(1 - \omega^2).$$

The circle r, θ is a line of electric force E. So, by the relation (69),

$$-2\pi r E\sin\theta = 6\pi v M\omega(1 - \omega^2)/r^2.$$

Or,

$$E = -\frac{3}{2}vM\sin 2\theta/r^3.$$

This could be got more simply, but we wanted an expression for G, and having it, made use of the relation (69) applied to a closed curve, or the Theorem of Version.

The last equation gives the strength of electric force at the point r, θ referred to the sphere's centre and axis of motion. The potential energy U of the displacement is

$$U = \Sigma cE^2/8\pi = \int\int\int \frac{c}{8\pi}\left(\frac{3vM}{r^3}\right)^2\omega^2(1 - \omega^2)r^2 dr d\omega d\phi$$

The limits for r are a and ∞; for ϕ, 0 and 2π; for ω, -1 and $+1$.

This gives

$$U = cv^2M^2/5a^3 = v^2M^2/5v_1^2a^3, \quad . \quad . \quad . \quad (76)$$

if v_1 is the velocity of light, the electromagnetic value of c being the reciprocal of v_1^2.

U is only a small fraction of T the magnetic energy of the sphere. This, by the formula $T = \Sigma\mu H^2/8\pi = \Sigma B^2/8\pi\mu$ is easily shown to be

$$T = 3M^2/a^3\mu(\mu + 2),$$

if μ be the permeability of the sphere, the outside value being unity. Thus, if $\mu = 1$ in the sphere also,

$$U/T = \tfrac{1}{5}v^2/v_1^2.$$

Travelling with the sphere, we have a steady electric field, and no current. But at a fixed point, the current, or rate of increase of displacement, is

$$c\dot{E}/4\pi = -(cv/4\pi)(dE/dz) = 3v^2M\sin\theta(1 - 3\cos^2\theta)/4\pi r^4 v_1^2.$$

As before remarked, the solution is the first approximation. In a complete theory there would be no discontinuity in the electric force at the surface of the magnet, as the above supposes, and there would be electric current in the magnet, with waste of energy by the Joule heating, thus requiring a continuously applied mechanical force to keep up the motion. Whilst, therefore, we should have disturbance inside the magnet, the solution outside would be not exactly that given. In fact, we see that the calculated dielectric current itself has its magnetic field, thus slightly altering the assumed magnetic field, that of the magnet at rest; and to the motion of this new magnetic field (very weak) there corresponds a new electric field, and so on. However insignificant these corrections may be in point of magnitude, they are yet required to make up a complete system satisfying the laws of induction. Taking, however, the above field of electric displacement by itself, we may close the magnetic currents in the appropriate manner on the surface of the magnet itself. The surface value of E is, by (75),

$$-\frac{3}{2}Mv\sin 2\theta/a^3, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (77)$$

and it is tangential. Hence the same expression divided by 4π, and taken positively, is, by the surface interpretation of (69), the strength of the complementary surface magnetic current, directed at right angles to the electric force—that is, along the meridional lines, if the poles be those points of the sphere cut by the line of motion through the centre. This system, with the former, makes a closed system of magnetic current, whose vector potential may be taken to be

$$Z = cMv\cos\theta/r^2, \text{ parallel to } z. \quad . \quad . \quad . \quad . \quad (78)$$

For this satisfies (67). This is literally the vector potential of a surface magnetic current of strength σv, parallel to z, σ being the surface density of free magnetism; but it is unnecessary to calculate the part due to the complementary current required to close it.

We can now check the value of U by the formula (72).

$$U = \tfrac{1}{2}\Sigma ZG = \tfrac{1}{2}\frac{3}{4\pi}\frac{Mv}{a^3}\frac{cMv}{a^2}\int\int\omega^2(1 - \omega^2)a^2 d\omega d\phi \quad . \quad . \quad (79)$$

Here we have to integrate the scalar product of Z and G through all space, Z being given by (78) and G by (74) outside the magnet, and by (77) (when divided by -4π) on its surface. But the volume integral outside the magnet vanishes, because Z contains Q_1 and G contains Q_3 as a factor (zonal harmonics). Hence there is simply the surface integral left, expressed by the right side of (79), the z component of the surface G alone counting. It gives the value (76) again.

The reason why (78) suffices for use in the formula $\frac{1}{2}\Sigma ZG = U$ is because G is completely closed. If, on the other hand, we employed the full formula for Z, we would not need to close G. A surface current σv parallel to z would then suffice. Thus, if $Z = Z_1 + Z_2$ and $G = G_1 + G_2$, wherein Z and G are both wholly closed, whilst the parts Z_2 and G_2 are polar, we have

$$\Sigma ZG = \Sigma(Z_1 + Z_2)G_1 = \Sigma Z_1(G_1 + G_2)$$

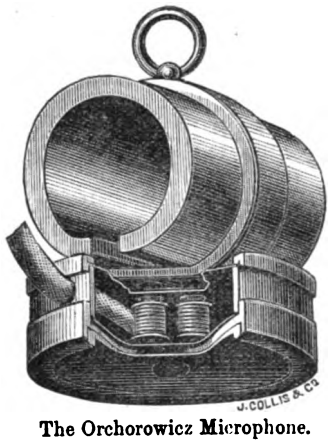
since

$$\Sigma ZG_2 = 0 \quad \text{and} \quad \Sigma Z_2 G = 0.$$

(To be continued.)

THE ORCHOROWICZ MICROPHONE.

A description of this powerful apparatus, the invention of Dr. Orchorowicz, will be found in *The Electrician* of February 21st and March 7th, of the present year. The system comprises, as will be seen from our illustration, a microphone



The Orchorowicz Microphone.

transmitter and a magnetic receiving telephone, the magnet of which is a steel cylinder, with a slot down the length of its surface about ¼in. in width, with two soft iron cores, three or four millimetres in diameter, arranged at the centre and carrying coils, which are enclosed in a case formed of two thin iron plates—one at the top opposite the cores in the usual manner, and the other at the bottom, the latter being screwed to the middle of the magnet. The lower plate is pierced with two holes of a larger diameter than the soft iron cores which traverse it, so as to ensure free movement; the two circular and parallel plates being connected together at their outer edges by a metal crown. In this way the two plates are only fixed by a point which connects the lower plate with the magnet, and form a vibrating box of great mobility.

THE EXHIBITION RECORD

Was of necessity begun in the last number of Vol. XIV. We shall be happy, however, to present those of our readers whose subscriptions commence with the present volume with a copy of the Supplement gratis upon application.

THE PARLIAMENTARY COMMITTEE AND TELEPHONE WIRES.

The forebodings expressed in our last week's leading article as to the result of the Parliamentary inquiry on overhead telephone wires were, it appears, more than warranted by what we have learnt since then. Although we could not give credit to the statements which appeared in the *Standard* and *Daily News* of Tuesday last, it now appears that they were not far away from the actual truth, at all events as to the substantial verdict of the Committee. The Report is almost certainly not unanimous; but the majority have emphatically decided to declare in favour of the overhead wire system, and of conferring fresh powers on the Telephone Companies for the furtherance of their business.

We are not surprised at this result, for reasons which we gave last week, and for other reasons which anybody can discover for himself who casts his eye over the names of the men who sat on the Committee. Parliamentary inquiries are not conducted on the principles which prevail in less exalted spheres. Interested parties may sit and report judicially in the Committee Rooms at Westminster whose testimony, even as witnesses, would be accepted with reserve elsewhere. Another odd thing about this particular Committee is that, although the Telephone interests are fully represented upon it, the inhabitants of London and the Postal Telegraph Department—who are the only two other parties concerned—are but imperfectly represented, the latter, in fact, not at all.

Fortunately, a Parliamentary Committee is peculiar in one or two other respects. It is usually instituted to stave off legislation when inconvenient questions arise which Parliament does not want to legislate upon; and, better still, its decision has no legal force. It is one of the fictions of Parliamentary life, very expensive but absolutely worthless. The present publication, however, we fear, will be rather mischievous as well as dear. According to the *Standard's* account, the Committee have reversed on every point the Draft Report of its Chairman, showing that at least there was one man present who drew his conclusions from the evidence, and not from his breeches' pockets.

The Report, which will be found in another column, declares that the risk of danger from overhead wires has been greatly exaggerated. After this it admits that these wires should be better controlled and supervised than they are at present; and the Committee then recommend that "the erection of overhead wires should be continued." As to the "control and supervision," we may take this phrase as a mere sop to the enemy, for it is made perfectly clear that neither control nor supervision is to "hamper the extension" of the system. The Committee are also of opinion that telephone wires should be allowed to pass over property without the owner's or occupier's consent; and that where the owners or occupiers refuse permission to attach wires to their premises the "local authorities" should be empowered to override such refusal. As to the possibility of placing the wires underground, the Committee are as silent as if such a proposition had never come under their notice. This fact of itself stamps the whole Report as a one-sided deliverance.

That these recommendations are so preposterous is the most cheering feature about them, for they will certainly never take shape in a legislative enactment. Before that stage is reached we may confidently predict that our notions of what constitutes a public danger will take a more definite shape through the unceasing activity of the Telephone Companies themselves. Overhead swinging signboards have long been disallowed in the busy thoroughfares of the City. They never killed anybody that we heard of, but they were considered dangerous; and it is perfectly certain, if the local authorities had any jurisdiction in the matter, that overhead street wires and the ricketty erections which are supposed to hold them together, but which in reality are kept up by the wires, would be voted a public danger without a moment's hesitation. This most certainly would be the case if the occupiers of the premises over which the wires run were the owners of them; and the danger is not lessened, but rather increased, by their belonging to an irresponsible and powerful company.

As to conferring powers on the companies to attach their appliances to premises without the consent of the owners, we may dismiss it with the remark that fresh powers would be required to prevent the occupier attacking the appliances with axe and hammer without the consent of the companies. There are usually two parties to an occupancy, sometimes three—the ground landlord, the leaseholder, and the tenant—any one of

Digitized by Google

whom could sue the other for b each of covenant if the Telephone invader is to have his way. But we may spare our arguments. An infringement of private rights so glaring would not be entertained, much less tolerated, by any legislative assembly in the world. The companies are posing themselves as public benefactors, and in that capacity hope to cajole Parliament into making extraordinary concessions; but the simple truth is that telephonic enterprise is a purely commercial affair, and that it is doing its work in the cheapest, flimsiest, and ugliest fashion in order to swell its dividends.

We do not blame the companies for this; but we do blame them for imagining that their attempted delusion will succeed, or that they can go on for ever on the principle they are working at present. Even their apparent triumph on this Parliamentary Committee would, if made a reality, prove disastrous to them. For, if Telephone Companies are to acquire exceptional rights, Electric Lighting Companies will claim them on equal terms, which could not be resisted. Yet, if Electric Lighting wires were carried in the beneficent—that is to say, cheapest—way the telephone wires have been carried, there would soon be an end to telephony. The two systems could not possibly live together; one of them would be rendered unworkable, and this one, we need hardly inform our readers, would not be the Electric Lighting.

OBITUARY.

It is with infinite regret that we learn the sad death of Mr. George Joseph Heraghty, the Superintendent of the Eastern and South African Telegraph Company's Station at Delagoa Bay, South Eastern Africa, which took place at Capetown on the 6th ultimo. Mr. Heraghty, who was in his 33rd year, was for many years in the service of the Eastern Telegraph Company at several of their principal stations, and on the coast line being opened in the commencement of 1880, left for Delagoa Bay, where he took a prominent part in the arrangement of the station buildings and the estate. As Relieving Superintendent he had successive charge of the Zanzibar and Mozambique Stations, besides the one to which he was finally appointed; and by his characteristic and unvarying generosity, his kindness and efficiency, won the affection and esteem of all who had the good fortune to come in contact with him. In Mr. Heraghty we cannot but feel that the company have lost an officer whom it will be difficult to replace, while many others, with ourselves, will deeply regret one who as a friend was beyond compare.

CORRESPONDENCE.

ELECTRICAL CONDITION v. RECENT SCIENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Coxworthy's letter on the above subject encourages me to give an account of some hitherto unpublished experiments made by me several years since.

Referring to my notes I find that on 3rd July, 1877, while a heavy thunderstorm (as I then erroneously supposed) was taking place about five miles away, and rain falling heavily on the spot, I took a gold leaf electroscope to a small grass plot, and after placing it "on the grass" (to quote my note book), "again raised it six feet; the leaves now diverged a quarter of an inch." Two years later I arranged a quadrant electrometer in connection with an insulated water-dropper close to the grass plot mentioned above. The observations were recorded graphically. On 2nd April, 1879, my experiments came to an untimely end by reason of an enormous and sudden rise of potential. At 1:30 p.m. on that day the spot of light shot off the scale like greased lightning, and I found, to my dismay, that the mirror was smashed, and the needle jammed tight in the quadrants. By carefully measuring the force necessary to extricate the needle I was able to estimate the value of the potential. This amounted to no less than 632,501·206 volts!

What could have caused this truly awful potential? I must confess I was totally unable to account for it until on reading a sentence in Mr. Coxworthy's letter a complete explanation flashed on my mind. Mr. Coxworthy, on page 535 of your valuable journal, observes:—"I . . . then found that the potato-leaf absorbed the moisture, whilst the grass did not, but *without doubt evolved electricity*" (the italics are mine; indeed, I may say that on reading that pregnant sentence I nearly went into "italics" myself).

The enormous potential may, then, have been due to a blade or blades of wet grass being blown (as it easily might) against the water-dropper!

Unfortunately, Mr. Coxworthy does not give us any measurements of the amount of electricity developed on wet grass; but my experiment of 3rd July, 1877, detailed above, enables me to supply this omission. We see that the leaves are deflected ¼in. when the electroscope was 6ft. from the grass, the grass being very wet, as it was raining hard at the time. We have here all the data necessary for determining, with some approach to accuracy, the potential at the surface of the grass plot, due to an element, say one blade of grass; for, assuming the number of blades to be infinite, and remembering the law of inverse squares, an easy application of the calculus shows this potential to be approximately 632,503·155 volts.

The coincidence of this value with that previously obtained is too striking to be the result of mere accident, and must be admitted by all competent electricians to be a triumphant confirmation of the new theory which we owe to the genius of Mr. Franklin Coxworthy.—Yours, &c., S.E.

May 9th, 1885.

THE STEAM ENGINE INDICATOR.—VI.*

BY AMICE.

Assuming that we have sufficiently described and illustrated the modern steam engine indicator, and given a general idea of the nature and purpose of the indicator diagram, we may now proceed to consider the application and employment of the indicator and the use in particular of the diagrams obtained by it.

We have, then, first to attach the indicator to the steam engine cylinder. This must be done so that the supply of steam to the indicator is perfectly free—that is to say, so that the pressure in the cylinder is faithfully represented by that on the indicator piston. To effect this the passage from the cylinder must in no way be obstructed either by the use of connections with bore smaller than that of the indicator cock, and in all cases where a nipple, socket, or pipe is required they should be larger than this. No harm can be done by having such fittings or connections of from half-inch to three-quarter inch bore. When possible, the indicator cock should be screwed direct into the cylinder or the cylinder cover. All good engine cylinders are provided with a boss at the cylinder ends, or a local thickening of the cylinder flange, as shown at B, Fig. 28, the flange at other parts being as seen at Fig. 29. In these sketches A is part of a horizontal engine cylinder, C the cover, P the steam port, E the slightly enlarged end of the cylinder by which clearance is given to the piston, the latter just passing the edge E, and thus the whole of that part of the cylinder which is of the diameter of the piston is swept through, and wear does not leave a rim at the ends of the original diameter of the cylinder which may do harm, when, by fitting the connecting rod with new brasses, the piston is made to sweep over the rim left as the connecting rod is shortened up by wear of the old brasses. The boss B, then, is screwed with a three-quarter inch Whitworth thread, this being the size usually adopted for the indicator cock D, the upper part of which is internally coned to fit the cone at the end of the indicator cylinder, as already shown at, for instance, Fig. 21. The lower

* For Art. 5, see *The Electrician*, 3rd January, 1885.

Digitized by Google

part of the hole in the boss B should be half an inch in diameter, and should be as near the end of the cylinder as possible, so that it is not covered by the steam engine piston, but at the same time it should be clear of the cover C.

Indicator diagrams should always be taken from both ends of a cylinder, as, although it may be supposed that the slide valve is accurately set, this is not necessarily the case. Moreover, the valve itself may not be properly proportioned, and the cut off and lead may alter with wear of the excentric and straps and the rod joint. There may be obstructions in one of the ports, the exhaust may not be so free from one end as the other, owing to misconstruction of the valve and the wear already mentioned. All these things would be found out by taking diagrams from both ends of the cylinder. For this purpose the boss (Figs. 28 and 29) should be made. When it

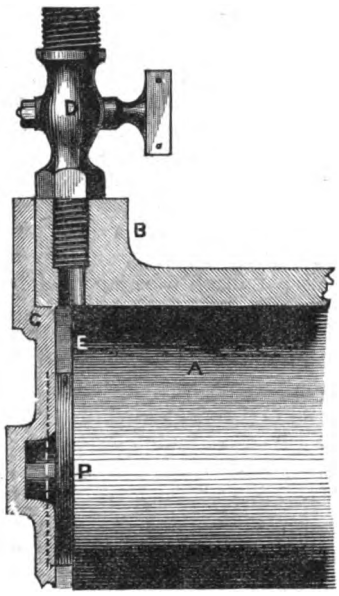

Fig. 28.

is desired to take diagrams at frequent intervals the two ends of the cylinder may be connected with a pipe, G, as shown at Fig. 29, which is one of several forms of such connections. A short piece, E, in the place of the cock shown at Fig 28, is screwed into the cylinder, the upper part of this being screwed

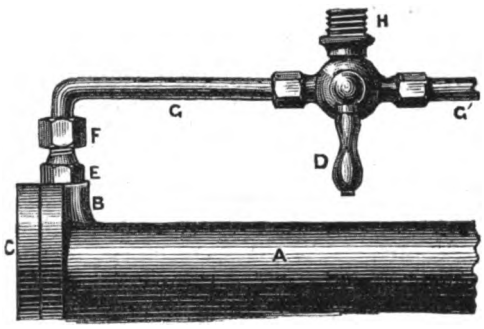

Fig. 29.

to take the union nut F, which is fitted to the end of the pipe G; the bend in the pipe should not be of small radius, although incorrectly shown with a short bend in the engraving, and should never be replaced by a right-angled elbow, as sudden bends have some effect on the flow of the steam, and may prevent the pressure in the indicator from instantaneously acquiring that which exists in the engine cylinder, and thus give an untrue rounded corner to the top of the steam end of the diagram. At D is a three way cock, C, by means of which the indicator is supported at H, and the steam admitted from either the one or the other end of the cylinder by the pipe G or G^1. The plug of the cock D should be made larger than would be sufficient for ordinary work, so that the hole through it should not only be large enough to pass steam freely, but so that the hole may be curved as shown at Fig. 30, which is a section of the three-way cock (Fig. 31) as made by the Crosby Steam-Gauge Valve Company for use with the Crosby indicator. It will be observed that the steam passes round an easy curve in this cock whether the plug be turned towards one or the other way. At one end of this cock is shown an expansion joint (Fig. 30), which for the temporary application of an indicator to different engines gives facility in connecting at and allows for expansion.

When this arrangement is adopted, the diagrams from both ends of the cylinder may be taken on the same cards as shown at Fig. 32, by simply turning the cock D, so that steam is alternately admitted from either end of the cylinder. This is of some advantage when diagrams have frequently to be taken, as the two diagrams are correctly placed in a comparative position, and a picture of what is going on during the strokes in both directions is obtained, from which a judgment of the working can be rapidly made.

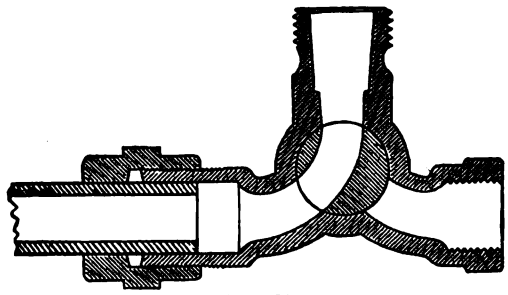

Fig. 30.

Where, however, only a few occasional diagrams have to be taken, and accurate measurements to be obtained from them, instead of simply obtaining a general diagnosis of the performance of the engine as far as the behaviour of the steam in

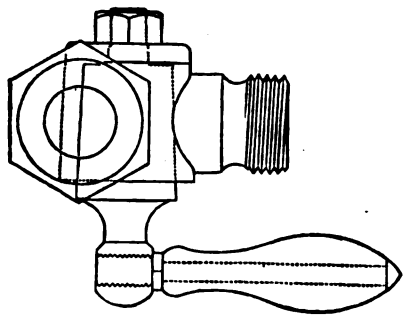

Fig. 31.

the cylinder is concerned, the separate diagrams are to be preferred. When large engines have to be indicated it is preferable that two indicators should be used rather than employing long pipe connections between the two ends of the cylinder.

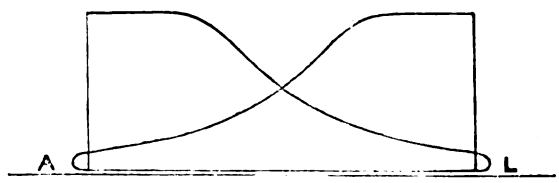

Fig. 32.

Steam in long pipes is likely to condense, and the presence of water in the pipes or in the indicator will destroy the truth of the diagram. The full pressure of the steam in the cylinder is not shown at the commencement of the stroke on the diagram, and the steam line is made irregular by the action of the water in pipe connections. In order to take two diagrams at nearly the same time, it is therefore necessary to employ an indicator at each end of the cylinder. For the purposes, however, of a general indication of the working of an engine on continuous work, as in flour mills, and its power, one indicator moved from time to time may be sufficient.

When vertical engines have to be indicated, an arrangement similar to that shown at Fig. 29 may be employed. This would hold the indicator in a horizontal position, which is in

Digitized by Google

some respects undesirable, and may be avoided by having a bend fitted to the three-way cock, with a socket into which the indicator cock may be screwed. When this arrangement is not used, the indicator may be screwed direct into the top cylinder cover for the upper end of the cylinder, and for the lower end a pipe with bends must be used, so as to bring the indicator clear of the cylinder, and in a vertical position. The position for fixing must always be chosen with reference to the part of the engine from which motion is obtained for the indicator drum. When the pipe connections are not so attached that water may easily drain away from them, they should be provided with a small cock by which it may be allowed to escape. Provision for this should always be made. In all cases care should be taken that these connections are properly and firmly made and steam tight, and they should be strong, so that the indicator may be firmly held. It costs little more to do the work well, and diagrams upon which reliance may be placed cannot be obtained with the indicator hastily and badly applied with makeshift connections. If diagrams are wanted at all they should be accurate, and if it is worth taking them, it is worth taking them well.

REPORT OF THE OVERHEAD WIRES COMMITTEE.

The Select Committee appointed to consider the law relating to the control over telephone, telegraph, and other wires have agreed to the following Report :—

After careful consideration of the evidence, your Committee have come to the conclusion that the risk of danger to the public from overhead wires has been very greatly exaggerated.

The accidents which have been proved in evidence have been few and insignificant. In the most important instance the fatal result was due, not to the breaking of the telegraph wire, but to a well-meant attempt by a member of the public to replace it.

At the same time, your Committee are of opinion that the probable development of the telephonic system makes it desirable that there should be some change in the law relating to control over wires, with a view to their better supervision.

Regarding the free development and use of the telephonic system as essential to the public convenience, your Committee cannot recommend any course which would materially hamper its extension. The system of public telephone exchanges, whereby persons at considerable distances apart may converse freely the one with the other is a great public convenience. The number of subscribers to these exchanges is already over 12,000; the number of messages sent during the year was over 41,000,000; and the average cost per message was less than one penny. This system is daily growing, now that increased facilities have been given for the purpose by the Postmaster-General. In London alone the number of subscribers is nearly 4,000; but the capability of development may be estimated by the fact that, according to the evidence of Mr. Preece (electrician to the Post Office), there are more subscribers to the telephone system in New York and its neighbourhood than in the whole United Kingdom, notwithstanding that the charge in New York is about double what it is here. The annual number of messages in London is over 15,000,000.

The companies have recently proposed to place every post office in the London district upon their exchange system, upon any reasonable terms to which the Postmaster-General may agree, so as to afford the entire public of London the means of instantly conversing with subscribers to the system, and similar offers have been made by other companies for towns in their districts; and the Committee therefore recommend that the erection of overhead wires should be continued, subject to proper regulation and supervision.

Your Committee are of opinion that, under proper regulations, permission should be given to pass wires over property without the owners or occupiers having the right of prohibition; but this facility should confer upon those enjoying it no vested interest or easement, and should not relieve them from any claim for damage occasioned by them.

It was given in evidence that many of the inhabitants of the Inner Temple are desirous of being connected with the telephone exchange, but that the Telephone Company is unable to obtain permission to run wires for them. It was also given in evidence that a similar prohibition has been exercised in the case of Covent Garden.

Your Committee think that in special cases, where it could be proved to the satisfaction of the local authority on investigating the whole circumstances that certain individuals or certain districts were debarred from the public convenience of telephonic communication owing to such refusal, the local authority should be authorised to give permission to attach wires to premises under suitable regulations and on payment of such compensation as the local authority might think just.

Bye-laws for the regulation of all wires, as to substance, length of span, durability, and other matters, and for their identification and inspection, should be made for the whole of London by the Metropolitan Board of Works, for provincial towns by the corporation, for rural districts by the local authority, in each case subject to the sanction of the Board of Trade. In London the enforcement of these bye-laws should be entrusted to the Corporation of the City, and to the vestries and district boards.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(Continued from page 517, Vol. XIV.)

TABLE OF CONTENTS.

CHAPTER IV. *Discursive.*†

19. Discussion and hypothetical explanation of true or thermo-electric contact force, and reason why for insulators it is large, and for metals small.
20. Thermoelectric contact-forces between metals and electrolytes, and theory of the common or simple voltaic cell.
21. Experimental examination of three simple cells used like voltameters; and dependence of E.M.F. on current.
22. Summary of condensed statements embodying the writer's own views.
23. Explanation of the last of the above statements. Example of a Peltier series and of a Thomson series; and question whether thermo-electric contact-force depends upon chemical tendency or whether it is purely physical.
24. Brief summary of the argument relating to the seat of E.M.F. in a pile.

19. Having now explained why I believe the main part of the Volta-effect to take its rise at the surface of contact between metal and medium rather than between metal and metal, it remains to consider whether this belief requires one to assert that there is no true contact-force at all at the junction of two metals. By no means: the existence of such a force is undoubted; but for metals it is usually very small and may be neglected in comparison with the Volta-force, though, strictly speaking, what is observed electroscopically is a mixture of the two. It is the true contact-force which gives rise to the Peltier effect, and its variation with temperature (assisted by the Thomson effect) causes thermo-electric currents. A contact-force exists, as Thomson has shown, not only at the junction of two different metals, but also between parts of the same metal at different temperatures.

In another place‡ I have endeavoured to gain some insight into the nature of this true contact-force and to suggest its cause. This has been done by many others; but I may be permitted to repeat my own notion, vague and incomplete though it avowedly is. Molecules of matter do not move in independence of electricity; at any rate the converse is certainly true—electricity does not move independently of matter. Electricity, in flowing through a wire, meets with resistance; there is something analogous to friction between the matter and the electricity, and the opposing force is precisely proportional to the strength of the current. This much is expressed by Ohm's law, $E = RC$, which is a carefully verified through empirical statement. But, analysing R into specific resistance of material (ρ) and sectional area of conductor, and permitting ourselves to regard $\frac{C}{\text{area}}$ as proportional to the velocity of electricity in a circuit of different thicknesses, we perceive that Ohm's law means that

$$\frac{dV}{dx} = \rho \times \text{velocity}.$$

* Reprinted from the *Phil. Mag.* for May.

† Very little of this chapter, and none of Chapter V., has yet been read anywhere.

‡ *Phil. Mag.* December (Supplement) 1876, "On a Mechanical Illustration of Thermoelectric Phenomena."

Digitized by Google

Let us then postulate, between electricity and any given kind of conducting matter, a connection which shows itself as an E.M.F. proportional to the speed of their relative motion and to the specific resistance of the material. Molecules of matter are not at rest, but (say) vibrating at a rate depending on, or rather itself determining, the temperature. These motions, as we have seen, cannot be independent of electricity, but they result in no force urging it to flow, because their motions are symmetrical. But place two metals in contact—one hot, the other cold; or one copper, the other iron: at the junction symmetry disappears, there must be constraint and accommodation; and, in whatever precise way this acts, it seems probable that it can be conceived of as having the same effect as a layer of molecules moving faster on their outward journey than on their return. If any such dissymmetry of velocity were produced, it would exert a propelling force on electricity* in the direction of the greatest velocity, because the force is proportional to the velocity. This is the crude and tentative way in which I picture to myself the Seebeck or true contact-force—the cause of thermo-electricity and of the Peltier phenomenon.

But now, why is this force so small in ordinary metals? Because it depends on ρ, the specific resistance, and this is small. Choose badly conducting metals like bismuth and antimony, or still better selenium and tellurium, and the force will be greatly increased. Choose so-called nonconductors, like glass and silk and ebonite, and it becomes enormous. But when one uses nonconductors we cannot expect to excite currents flowing in closed circuits; we can only expect electrical displacement and electrostatic phenomena; and indeed it is no such easy matter for electricity to move in such substances, even though the force urging it be excessive; and a little mechanical violence (friction) may be necessary to help it to move. But remember that no amount of friction can determine the motion in one direction rather than another; working a pump-piston exhausts no air unless there are valves. Friction may supply some of the energy, but the directing force must be in the substances in contact†. To assist the passage it is customary in electrical machines to touch together a conductor and insulator rather than two insulators. I doubt not that when metal touches glass the surface of contact would become chilled as soon as any transfer of electricity were really produced by the force; but the heat developed, by the friction apparently necessary to aid the transfer, effectually masks any chilling.

Measurement of contact force between insulators is beset with difficulties, because it is so difficult to make electricity pass across the junction. No limit to the force has at present been observed: whenever an electrical machine reaches its limit, and refuses to charge its prime conductor or a Leyden jar to a higher potential, it is accounted for by saying that the rate of leakage is now equal to the rate of production (which is undeniably true), but nothing is said about whether the rate of production is the same as it was when the jar was uncharged. It is a difficult matter to settle, because most of the leakage takes place close to the rubber; and, though it is quite possible, it is unlikely that a limit to the force will be discovered, by finding the activity of a frictional machine less at high potentials than at low. When the substances in contact are two metals, it is impossible for them to drive electricity very hard, for it would, so to speak, slip through their fingers; but when an insulator is concerned, its grip is so great that probably there is no limit to the force until its insulating power is overcome, and through it also electricity begins to slip. Certainly any upper limit must be a very high one, for the force can readily pile up a charge till it produces sparks a foot or more long.

Whether *Volta* forces, or contact-forces between substances and the medium surrounding them, exist for insulators also we do not know; we have no reason whatever to deny their existence; but whereas in the case of metals these exceeded the forces acting between the substances themselves, here in the case of insulators they are absolutely negligible by comparison. For intermediate substances they may have correspondingly important values; and it seems not unlikely that at the junction of metals with electrolytes, and of electrolytes with one another, the total contact-force may be a complex one—partly chemical, and due to the possibilities of chemical action straining across the junction, and partly physical, due to different velocity of the molecules.

20. The preliminary experiments of Bouty have caused him to believe in the existence of physical contact-forces, at the junction of metals with electrolytes, which cannot be brought into harmony with energies of chemical action. And though the subject is too unexplored in this direction to be ripe for discussion, it may be well to point out that these contact-forces are important in the theory of the voltaic cell even in its simplest form.

Why is the E.M.F. of a zinc-copper battery less than that of a zinc-platinum?

Why is the E.M.F. of a zinc-lead or iron battery smaller than either?

The chemical action goes on in each, zinc is dissolved at one end and hydrogen liberated at the other: how, then, can the E.M.F. be different if it is calculable from the chemical reactions?‡

If we picture to ourselves the actual forces in action we shall get a kind of answer indicated to us. In a zinc-iron cell the E.M.F. is due to the zinc pulling at oxygen harder than the iron does; but, since the iron does pull too, with no inconsiderable strength, the balance of force is not so great as if the iron were replaced by copper, which pulls less, or by platinum, which barely pulls at all until it is coated and alloyed with hydrogen.

This answer cannot be considered as complete, and in order to complete it consider a more precise experiment.

Arrange a series of common dilute acid voltameters, with their plates respectively, zinc zinc, zinc iron, zinc copper, and zinc platinum. Pass one current through the series, from zinc to the other metal, and measure the differences of potential between the plates in each cell. Now the same chemical action is going on in each. In each zinc is dissolved at one side and hydrogen evolved at the other—the only difference being that it is liberated from surfaces of zinc, iron, copper, platinum, in the four cases. What is to prevent the E.M.F. between the terminals of each voltameter from being the same? But it is not the same (*pace* Prof. Exner): the zinc-zinc cell shows the greatest difference of potential between its terminals, the zinc-iron less; and the zinc-platinum may easily show a reverse difference because it helps the current on instead of hindering it. It will be understood that the *precise* behaviour of the cells is determined by the intensity of the current (*i.e.*, current per area)—if it is weak, even the zinc-iron cell may help it on, but the zinc-platinum will help it on most: if it is very strong, even the zinc-platinum will retard it, but the others will retard it more, and the zinc-zinc most.

Now, why is all this? Take the difference between the heats of formation of Zn,SO_4 and of H_2, SO_4, at the comma, and you will have the total energy assimilated by the current in each cell. This energy is the same in all the cells, but not in all does it take the same form. In the zinc-platinum cell it mainly results in driving the current forward. In the zinc-zinc cell it wholly results in a Peltier (or Bouty) generation of heat. In going out of the cell by a cathode zinc plate, it has to move hydrogen towards it, and (*ipso facto*) oxygen away from it, in opposition to the strong chemical attraction; thus it will do work and liberate energy, which, since there is nothing better to do, must exhibit itself as heat. At an iron surface less heat is generated, and at a copper less still; but, at any cathode which attracts oxygen, some heat must be generated by a current made to do work in opposition to this attraction.

In the zinc-zinc cell there is no propulsion of electricity at all by the cell; on one side, where the current enters, zinc is dissolved and the current helped forward with the full energy (or nearly the full energy) of the combination, so that no (or nearly no) waste energy or heat is there produced; but on the other side, where the current leaves, the same combination is (not exactly undone but) opposed and the current hindered with (probably something less than) the full energy of the combination, and there the heat of combination is generated.

Thus, regarding the passage of hydrogen to the cathode as a virtual separation of O (or SO_4) from it, we may say in general that in any one of the above cells used as a volta-meter, the energy available for helping the current on is that represented by the difference between the combination energies of the substances respectively attacked and liberated; *i.e.*, $Zn, SO_4 - H_2, SO_4$; but that besides this, the combination M, SO_4 is virtually undone; and, since the energy of this combination appears as a generation of heat at the cathode, it is so much to be subtracted from the propelling force available for the current, only the balance being leit for this purpose, viz.,

$$Zn, SO_4 - H_2, SO_4 - M, SO_4.$$

Whether one ought to write SO_4 or O in these expressions I am not sure, but it is not essential to decide this at present.

Another way of regarding the matter is to say that the force propelling the current is that due to the difference of energies Zn, O—M, O, but that as soon as a current actually passes and hydrogen is libereted it coats the cathode more or less thickly, and an extra term must be subtracted from the above to represent the opposition force of this hydrogen. The efficacy of this hydrogen as a current-opposer must depend in some way on the intensity of the current itself, since with the feeble current it will be able to dissipate itself faster than it forms, and with a strong current it will thoroughly coat the plate and the balance will escape. Suppose, then, we represent the force exerted by the hydrogen as $H_2O\,f(C)$; where $f(0) = 0$, and $f(\infty) = 1$ or something like 1; then the force available for urging the current forward in any of the above cells is, in volts,

$$\tfrac{1}{40000}\{Zn,O - M,O - H_2,O\,f(C)\}.$$

There is an obvious objection to be taken to this last hypothesis, viz. that it supposes the second metal M completely operative, even though it be thoroughly coated with hydrogen. This is hardly reasonable; and a compromise between the two preceding hypotheses is afforded by one of greater generality in which the available force is symbolically represented by

$$Zn - M\,\phi(C) - H_2 f(C),$$

where ϕ is a function such perhaps that $\phi(C) = 1 \div n.f(C)$.

On this hypothesis the propelling E.M.F. is

$$e = \tfrac{1}{40000}\{Zn, O - M, O - (H_2, O + n\,.\,M, O)\,f(C)\}.$$

* I do not say necessarily on *positive* electricity. It seems a complication; but Sir William's researches show that it is positive in some metals and negative in others. In the case of lead only does the grip on both electricities seem the same.

† Mr. Joseph Thomson (*Proc.* Roy. Soc. 1876) endeavoured to extend ordinary contact methods to non-conductors. He was hardly likely to get very clear results; but he was able to find some electrical transfer as the result of mere contact, if it be admitted that it is possible to apply mere contact and no sort or kind of violence—a supposition which is probably inadmissible. Yet the least violence destroys all novelty, and sends us back to Thales.

‡ Professor Exner cuts this knot in characteristic fashion by asserting roundly that the E.M.F. of all such cells is the same, and that it matters not hing what metal is opposed to the zinc of a cell so long as it does not alter the chemical action going on. He further asserts that all batteries are non-polarisable and quite constant, as soon as they have got rid of dissolved air and before sulphate of zinc has accumulated. He verifies these extraordinary statements, to three significant figures, by straightforward experiment. See his paper "On Inconstant Voltaic Batteries," cited above.

Digitized by Google

This is too much like miscellaneous guessing, and we will make no more of such hypotheses ; but if experiment could fix an empirical formula for this force in any case, we could apparently at once obtain the Joule or Bouty effect,* or rather the difference of two such effects, for that case ; because we should have the E.M.F. experimentally observed on the one hand, and that calculated from pure energy considerations on the other, as

$$\frac{Zn, O - H_2, O}{46000} + B_M - B_Z,$$

where the two B's stand for the Bouty coefficients at the zinc and the other metal respectively. The only objection is that in the cells now under discussion M is coated more or less with hydrogen, and hence the Bouty effect obtained is nothing very easily definable.

(To be continued.)

PHILADELPHIA EXHIBITION.

(Continued from page 380, Vol. XIV.)

The National Underground Electric Company of New Jersey.

("C." of the Section's Classification.)

This conduit consists of a number of metal tubes imbedded in a kind of insulating pitch, formed in a suitable trough. At the corner of each street there is a water-tight manhole for hauling in or out wires as required. Provision is also made for tapping wires for house-to-house supply. This forms the subject of a separate patent. It is proposed to place telephone, telegraph, and electric light wires in different tubes, so that they shall not interfere with one another. The metallic lining of the ducts, it is claimed, will pass off readily any induced currents which may be generated. The moisture or damp can be kept out by forcing dry air through one or more of the tubes or conduits from a fixed plane along the line.

The company state that the cost of the conduit per mile will be $8,300. A mile of conduit has been laid under Market-street, Philadelphia. The committee were unable to examine its condition, as it contains no wires at present.

Hendley's Conduit for Underground Lines.

("A. b." of the Section's Classification.)

This system consists of a semi-cylindrical trough or conduit for the reception of the conductors, with a suitable cover of any desired configuration, angular shaped being preferred, as by its removal, when necessary, the wires and their supports are more thoroughly exposed. Below the trough and integral therewith is a drain pipe of suitable diameter, for carrying off all moisture that may finds its way into the conduit by condensation, exudation, or leakage. A narrow slot extending throughout the length of the trough opens therefrom into the drain pipe, the curved sides of the former rendering it almost impossible for any heavy particles of moisture to remain therein. This slot serves also to sustain the bolts which pass through the shoe to which the standard of the wire supports are secured, thus rendering it easy to place the supports at such intervals as may be desired along the conduit. This structure, with the supporting arms is really "a telegraph underground." Modifications of these slotted arms have been suggested which it is thought would, in practice, make this feature thoroughly effective.

Testing chambers are placed at such suitable points along the line as may be necessary, and in these provision is made to test, tighten, and otherwise manipulate the wires. A full description of this feature of the system cannot be fully set forth herein. At one side of the conduit brackets are secured, and from these rods extend, over which travellers having suitable pulleys in their interior which move on the rods, pass and carry the wires from manhole to manhole ; cords are attached to each side of a traveller, and pass thence to reels secured near the surface of the earth. These manholes can be placed at frequent intervals along the line, by securing wires to a suitable clamp at the bottom of the traveller, and they may be run in at any point simply by reeling in the cord.

Pipes for inducing currents of air are led into chimney stacks, the heat of which is made available for that purpose, or they may pass into the open upper air, and currents of hot or cold dry air may be forced into the conduit by means of fan blowers. Both devices may be used, though either separately would be effective, for carrying off all the lighter particles of moisture, and thereby keeping the conduit thoroughly dry and at a uniform temperature all the year round, and thus rendering, it is thought, a thorough insulation of the conductors unnecessary. Provision may be made by this system for a future increase in the number of conductors to be employed without having to tear up the streets, so that when once the system is built it remains a permanent and available plant, adapted not only to present but to future use.

Comments by Examiners.

This conduit consists of a semi-cylindrical trough of iron, terra cotta, or, preferably, of glass, fitted with an angular-shaped cover. At the bottom of the conduit there is a pipe connected to it by a slot for the purposes of drainage, and for fixing a standard with recessed and insulated arms for carrying the wires.

Manholes are provided at suitable points, and also small pipes for house-to-house supply.

* That is the thermo-electric contact-force at a metal-liquid junction ; see section 6.

Provision is made for either ventilating the conduit by induced currents of air, or of forcing hot or cold air through it in order to expel all moisture. No provision is made for induction in telephone wires. The standards carrying the wires are secured to the conduit by one bolt each, and it would seem difficult, without continual inspection, to keep them in position.

Magner's Underground Conduit.

("A. b." of the Section's Classification.)

This system consists of a conduit constructed of cast iron, terra cotta, &c., having a longitudinal slot A' at its top, for the introduction of wires or cables. This slot is bevelled and made tight by bolts and clamps bearing on the inside of the conduit. The joint is further secured by suitable packing.

The wires or cables are supported on insulated rollers, which revolve freely on a series of horizontal shafts, suitably supported and arranged one over the other. These rollers may be formed in one piece, or may consist of a number of independent rollers separated by washers. The distance apart of the rollers, both horizontally and vertically, is such as to prevent contact between the wires or cables when strained up.

The inventor claims that his system provides a conduit applicable to all descriptions of wire or cable, which is easy of access for the insertion or removal of any wire or cable, and in which the wires are kept taut.

The inventor did not submit any plan for manholes, or any arrangement for providing house-to-house supply, nor does he claim any method of obviating the efforts of induction. He proposes to lay down well insulated wires, as the conduit would be necessarily more or less damp.

After the conduit has been laid and filled with wire, any alteration to the system would require that the street should be opened from end to end.

Philadelphia and Seaboard Telegraph and Cable Company.

("A. a." of the Section's Classification.)

The material used in constructing this conduit consists of hemlock wood, copper wire, various compounds and insulations, the nature of which the inventor did not disclose.

The wood is exposed to a solution for several hours, at the temperature of boiling water. The composition being easily distributed through the mass of soft wood, incrusts the cells with a compound which makes the wood absolutely moisture and decay proof. The carpenters now take the wood (which has become dry and hard) and make a hollow box—the core of the conduit—which is filled in with insulated telephone wires, arranged according to a plan not disclosed. When the core is filled, insulating material is again poured upon the wires, filling in the interstices, making a dry solid mass. The top is now cemented on. The finished core now receives a second coating of the waterproof compound. Around this core are now built the receptacles for the insulated telegraph conductors. There are two inches of insulating impermeable compound between the telephone and telegraph circuits, 6in. between all sides, ½in. all round.

The finished core is now set in the outer shell of the conduit, which is also made of the prepared wood 1in. thick. A moistening compound is now run in around the core and the top covered with a plank of the same prepared wood, pressing into the compound, making two inches of solid impermeable matter between the core and the casing, three inches between the core and the earth, five inches between the telephone and the earth. The sections are all prepared at the factory before being taken on the ground. They are run into sleeves every 20ft. Twenty loops are run out on each side of the sleeve and covered with a waterproof cap, so that the wires are at all times accessible. The wires are connected through the sleeve with a patent, hard paper, double connector.

The electric light conduit is made in a similar manner, but the wires are widely separated, and different materials are used in insulating and fire waterproofing.

The advantages claimed for this system are :—(1) It is fireproof ; (2) it is waterproof, it will not decay ; (3) it is a perfect insulator ; (4) no leakage between telephone and telegraph wires ; (5) the arrangement of the conductors in the lanes to divert induction, &c. ; (6) the wires will not corrode ; (7) the wires cannot break, no pulling of cables through tubes, no abrading, no strain ; (8) insulated wires can be tapped and conveyed into each dwelling without disturbing the main conduit ; (9) it is cheaper than a pole line.

	Price per mile.
100 Telephone wires, delivered on ground	$2,500
1,000 Telephone wires, delivered on ground	$9,750
100 Telegraph wires, delivered on ground	$2,750
1,000 Telegraph wires, delivered on ground	$12,750

Comments by the Examiners.

The whole success of this system would depend on the nature of the insulating material and the chemical preparation of the wood, &c. Without trial, over an extended period of time, it would not be possible to test this conduit for endurance and the other points claimed by the inventor.

The Union Electric Underground Company of Chicago.

("A.a." of the Section's Classification.)

This conduit consists of a tube 10in. in diameter of kalamine (a mixture of lead and tin), which is said to resist the chemical action to which all underground conduits are subjected—on each side of this main small tubes of the same metal 2in. in diameter. The large tube is designed to accom-

Digitized by Google

modate the main wires and the small tubes those which run short distances ; and at regular intervals there are joints by which house-to-house connection can be made. Instead of the wires being covered with an insulating coat, from which they cannot be withdrawn, they run through a tiny pipe, a little smaller than the familiar macaroni tube, and this pipe is manufactured independently of the copper wire. When this pipe has been tested the copper wire is forced into it by an ingenious machine. Should the copper wire at any time need repairing the same machine withdraws it from the well-fitting covering and then replaces it.

The inventor claims that this tiny tube is the best insulator known. It is made of vulcanised rubber, three sixteenths of an inch being its thickness, and one-sixteenth of an inch being the diameter of the opening. The rubber is covered with a thick electric deposition of copper. The deposition surrounds the tube and is said to prevent induction by carrying the surplus electricity into the ground.

By the tube system each wire can be removed without the others, with which it is bunched, being disturbed in any way The electric light wire which, on account of the great insulation, can be handled with perfect safety when the strongest current of electricity is running on it, costs less than $500 a mile, or half the usual cost, and takes up about half the space that an electric light wire usually occupies.

The inventor claims that by the use of his special insulation he can run all descriptions of wire in one tube.

The conduit can be laid for $8,000 a mile. The main tube will hold 1,700 wires, and the side tubes 50 each.

The insulation was found to be very brittle, and it would be difficult to bend it out of the manholes and tapping tubes without injury. The wires must be necessarily very expensive, not only to manufacture, but to force into their insulated tubes afterwards.

WOODWARD'S CURB CONDUIT.—SYSTEM B.

("A. b." of the Section's Clasification.)

In the accompanying engraving, Fig. 1 is a perspective view of the combined curbstone and conduit, showing the wires in position ; in the second figure the wires and cover are removed. The hollow curb conduit sections, A, made of cast iron or other suitable material, are formed with

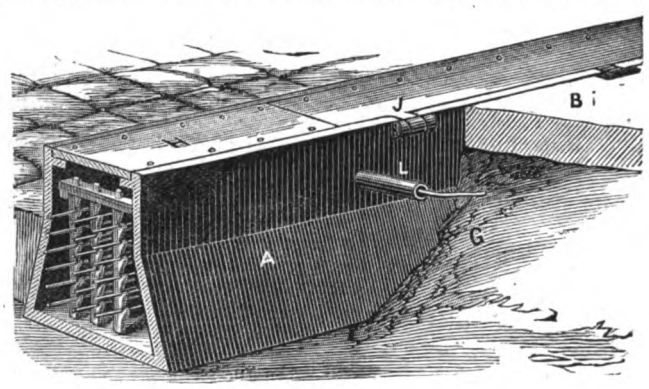

FIG. 1.

vertical sides above the street pavement to form the curb, and those portions sunk in the ground are widened out at the bottom to guard against displacement and provide ample space. The cover J is about flush with the sidewalk. Between the cover and the top of the ledges is placed a water-tight packing. The wires are supported by a series of vertical racks, E, fixed at suitable intervals apart. The lower ends of the racks enter sockets in the bottom of the conduit, while their upper ends pass through holes in cross stays, D, the extremities of which rest in brackets on the sides. The ends of the conduit section are flanged and bolted together, packing being inserted between them.

When it is necessary to provide for longitudinal expansion and contraction of the several sections, they are made with overlapping ends, and are secured by bolts passing through slots in one of the flanges. Packing is placed between the joints. The wires are inserted from the open top of the conduit and rest in the teeth of the racks ; after they are in position the cover is bolted down. When it is desired to conduct one or more wires into a building, small lateral pipes, L, are connected to the side of the conduit. With this construction the wires are always easily accessible and the tearing up of the pavement in order to reach particular points is obviated. The two-plan views show clearly the methods of rounding corners. When the conduit crosses the street where the curb ends, those wires which are above the line of the depressed part are directed downward, and kept in place by means of tranverse studs.

The advantages claimed for this system are: That it is easier and cheaper to place the wires in the curb than to tear up the streets and put them in an underground conduit.

That owing to the curb conduit widening and deepening from the level of the paved street it gives ample room for holding any number of wires.

That to introduce into a house any telegraph, telephone, or electric light wires, by merely removing a few bricks from his pavement, the connection is made direct with the curb conduit, instead of excavating many feet of earth in the pavement and the street by the underground conduit.

That it is always accessible.

If anything happens to a wire, or a new one is to be introduced, one can always get to it in the curb conduit, and during the snow and ice of winter, when the authorities of cities will not allow the streets to be opened, the curb conduit is as accessible as in the warm months of summer.

Comments by the Examiners.

In this system no provision is made for keeping the conduit free from moisture, so that a first class insulation is required for the wires or cables used. Further, no method is proposed for obviating the efforts of induction in telephone circuits.

To obtain the advantages claimed for it, a conduit must be run on both sides of the street in order to give house-to-house supply.

It would further appear that a long line of iron plate along the side walk would be dangerous to foot passengers in frosty weather, and would interfere with present arrangement of gas lamps and the existing sub-pavement and street cellars.

No estimate of cost was given. The system would necessarily be an expensive one.

(To be continued.)

COMPANIES' MEETINGS & REPORTS.

London Platino-Brazilian Telegraph Company (Limited).

The seventh ordinary general meeting of the shareholders of this Company was held at the offices, No. 66, Old Broad-street, on the 11th inst., under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. William Payton) having read the notice convening the meeting and the minutes of the last meeting, the report of the Directors was taken as read.

The CHAIRMAN : In the remarks I have to make I must draw your attention first to the fact that there has been an increase in the receipts over the land lines in Uruguay. The amount was £2,646 in 1883, and in 1884 it was £3,271, showing an increase of £625 over the preceding year's receipts. Since I last had the pleasure of addressing you we have been paid the debt which the Government of Uruguay had been owing to us for a very considerable time—a debt which at one period we were not over sanguine about. Thanks, however, to Senor Lanza, who has been very persistent with, but, at the same time, very conciliatory towards, the Government, that debt, which stood at £7,360, has been paid off, but it was paid off in bonds at par. As you may observe from the accounts, their realisation shows a loss of £2,937. I may say that that is a settlement much in the same way as other debts have been arranged, and I think that on the whole we have rather reason to congratulate ourselves on having been paid. The Government accounts have been paid to the end of January, and we have urged our agent to see that the Government pay their messages' account in future with regularity. I am glad to find that our agent is on very friendly terms with the Government, who, as we all know, is not very rich or flush of money ; but they appreciate the mode in which we are doing our work, and consequently they are the more disposed to pay accounts, the non-payment of which they know would eventually embarrass them, because without a return on our land system we are not likely to maintain it in the efficient state in which it ought to be maintained. Our agent writes to us, "The President of the Republic, to whom, from the first alarm of the invasion, I offered without limit the use of the lines, has stated that he is very much satisfied with the rapidity and exactitude with which the telegraph service of this Company has been carried out, and also with the willingness of the clerks." I may mention that through the issue of the *pronunciamiento* a considerable amount of telegraphing was caused on the part of the Government ; and since this matter has been settled, more or less, trade has resumed, and we are therefore doing a very fair business at the present time. With regard to the cable receipts, there is a falling off. The revenue in 1883 was £12,638, while for the past year (1884) it was £10,655, a difference of nearly £2,000—a sum sufficient to pay another half per cent. dividend. Our dividend last year was 2 per cent., whereas this year it is only 1½ per cent., but we carry over a tangible sum—£1,046—available for reserve for the equalisation of dividend in future, or otherwise, as occasion may warrant. Some portion of the decrease is attributable to an interruption of the cable of the Brazilian Submarine Company for more than three weeks in March, 1884 ; but it is mainly owing to the reduction of the tariff over the Western and Brazilian Company's cables. It is satisfactory to know that the earnings of that company, in which we are so much interested, show a considerable increase since the 1st of January last over the corresponding period of 1884 ; but this improvement will appear in next year's accounts. As to the difference between the Western and Brazilian Company and this Company I may mention that the negotiations are still going on. They have been very prolonged ; but there have been many causes which have interfered with a settlement being brought about. In the first place there have been negotiations going on between the Western and Brazilian and the Brazilian Submarine Companies, which I am afraid have not come to anything like a satisfactory settlement. On the other hand, the Western and Brazilian Company have been attempting to make some arrangements with the Brazilian Government, who, I am sorry to say, are not acting in that spirit which they promised they would show when submarine telegraphy was first introduced on their shores. I mentioned, I think, when I addressed you last year, that in the early days of submarine telegraphy the Emperor of Brazil himself expressed the opinion that, while his country could not give the Company money by way of subsidy, they would give every possible facility in their power to

Digitized by Google

encourage the submarine cable system. The Government, acting behind him, I am afraid, have the power, and they are not acting up to the promises and the spirit of the statements made by the Emperor. What the result may be it is very difficult for me to say, but I hope that the Government of Brazil will find, in dealing with the submarine cable system, which has enormously benefited their territory, that unless they treat its proprietors in that liberal spirit which we consider we are entitled to, and in that honest spirit in which they are bound, as a Government, to act, the result will not be advantagous to them, and that they will find, in short, that after all "honesty is the best policy." Our negotiations with the Western and Brazilian Company are still going on, and I believe they have now advanced to the point of being in the hands of the respective solicitors. We may shortly hear the result of these negotiations, and before we take any step in completing them, I believe we are bound to put the whole case before our shareholders, and after that a special meeting will, if necessary, be called to give them full information as to what the bargain is. I think, gentlemen, that these remarks embrace pretty well all that I have to state, and I therefore beg to move: "That the report and accounts for the year ended March 31, 1885, submitted to this meeting be and they are hereby received and adopted, and that a dividend of 1s. 9d. per share be declared, payable this day, free of income tax."

Mr. JOHN HOLLOCOMBE seconded the motion.

The CHAIRMAN invited discussion, and expressed his readiness to answer, to the best of his ability, any question which might be asked of him. No shareholder, however, rising to speak, the resolution was put and carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. HOLLOCOMBE, Mr. Francis Pavy was re-elected to his seat at the Board, and subsequently on the motion of Mr. W. FORD, Messrs. Deloitte, Dever, Griffiths, and Co. were reappointed auditors.

Mr. FORD then proposed a vote of thanks to the Chairman and Directors for the way in which they had managed the affairs of the Company in the past year.

The resolution was seconded and carried unanimously; and, in reply,

The CHAIRMAN said: Gentlemen, I beg to thank you on behalf of my co-Directors and myself. I only wish that the concern were larger, and that I could offer you a greater dividend; but we are in a comparatively helpless state, because we are entirely dependent on the management of another concern for the dividend we pay you. Therefore, as I have already stated—and I repeat it now—I hope some satisfactory arrangements will be come to whereby this Company will be absorbed by a larger company—in short, I should not object to see the whole of the telegraphs on that coast under one system. I think the result would probably be—if proper financial arrangements could be made, to suit all parties—that not only would the shareholders be benefited but the public generally. I believe that "union is strength," and, as far as I am concerned—and I believe those associated with me take the same view—when the time comes when a general amalgamation should take place, you will not find us dissentients.

The proceedings then terminated.

Submarine Cables Trust.

The fourteenth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the Offices, No. 66, Old Broad-street, on the 12th inst., John Pender, Esq., M.P., in the chair.

The SECRETARY (Mr. Lewis Wells) having read the notice calling the meeting and the minutes of the last meeting, the report of the Trustees was taken as read.

The CHAIRMAN: Before I put the usual resolution I desire to make one or two remarks as to what has been done during the past year. The accounts now presented are made up in the usual form, giving the fullest information as to the position of the Trust. The amount which the Trust had to deal with last year as dividends on their investments, including the amount brought forward, was £24,449; and the expenses were £1,324. The payment of the coupons absorbed £20,289; in purchasing nine certificates £886 was spent; and we carry forward £1,950. With this balance and the dividend on the Eastern Extension Company's shares it is anticipated that we shall be able in the current year, in spite of the diminished dividends from the Anglo-American Company, to pay the coupons in full, and leave a small balance over. The Atlantic cable competition is a very serious matter. The present tariff is not one which can be regarded as remunerative. The last dividend received by us, a few days ago, from the Anglo-American Company, was only £490, against £1,544 in the corresponding quarter of 1884. This competition at the present moment is not likely to lead to higher dividends; the chances are, I am sorry to say, for a time, that they are very likely to lead to lower. The present tariff is not remunerative in any degree, even to the new company who have just established their line. The Mackay-Bennett Company must have been carried on at a very serious loss by the transfer of their money, which had been previously invested in American securities, into this system. As far as I can see, if they keep their accounts as they ought to, they cannot show much over 2½ per cent. That to them, with a new cable, and having all the advantages of modern science and lower costs, places them in a satisfactory position as far as competition is concerned. On the other hand, the Anglo-American Company and the other companies have a certain goodwill of the business, and if it comes to competition I have no doubt they will be able to do their business well and efficiently. At the same time, this will not bring the money, and what I look forward to by and bye is that it will be urged, in the interest of the shareholders, that some rearrangement of the present tariff should take place. When that is done this Trust Company will participate in the advantage which will accrue. Fortunately, however, there are other companies in which we hold a considerable interest who are doing decidedly better than they were; and the consequence is that what we lose by the Anglo-American Company we make up by the others. I therefore think we may rather congratulate ourselves that, by reason of the moneys we have in hand, we shall not have to default in the coupons. Almost one fifth of the capital of the Trust has been redeemed, and the market price of the certificates is about par, or 10 per cent. above the price of issue. We are entirely dependent on the income we receive from other companies, but, as a whole, our investments are such as to enable us to keep on paying our coupons in full, and I am very hopeful that before the year advances much further there will be some arrangement by which the Atlantic system will give a better dividend than it does at present. In that case we shall be benefited. I now move "That the report and accounts of the Trustees now submitted to the meeting be approved and adopted."

Sir DANIEL GOOCH, Bart., M.P., seconded the motion.

A SHAREHOLDER inquired whether there was much increase in the business in the Atlantic Companies.

The CHAIRMAN: I am sorry to say that the amount taken over all the systems is considerably less than last year.

The SHAREHOLDER said he had meant to ask if there was an increase of messages to any extent.

The CHAIRMAN: No, if there had been an increase of messages there would be an increase of revenue.

The SHAREHOLDER: The cheap rates do not increase the traffic?

The CHAIRMAN: No. When the Mackay-Bennett Company opened their system at 1s. 8d. a word against 2s., which was the rate previously charged, they caused a clear loss of £150,000, which you might just as well have thrown into the sea. The difference is so infinitesimal upon the amount of telegraphing that is passing that neither the sender nor the shareholder receives any benefit. I am hopeful that common sense will prevail eventually, and that we shall have a tariff established that will give a fair return to those who have put their money into Atlantic telegraphy.

The resolution was then put and carried unanimously.

On the motion of Mr. K. ANDERSON, Mr. John G. Griffiths and Mr. John Gane were re-elected auditors for the current year.

A vote of thanks was afterwards passed to the Chairman and Directors.

The CHAIRMAN: I am very much obliged to you, gentlemen, on behalf of my colleagues and myself. We are watching your interests and what the other companies are doing, and I hope when we meet next year we shall be able to tell you that there are better prospects for the Atlantic cables than I can show at the present time.

The proceedings then terminated.

Great Northern Telegraph Company of Copenhagen.

Abridged report of the annual general meeting, held at Copenhagen on the 25th April, 1885, F. Zahle, Esq., presiding.

The CHAIRMAN (C. F. Tietgen, Esq.) addressed the meeting with regard to the working year of 1884, by first of all referring to the cables owned by the Company. The state of the same had been so to say normal; there had been the ordinary rather numerous cases of interruptions, but in no instance had these sensibly affected the Company's receipts. Amongst these interruptions one, however, deserved to be specially referred to, viz., a breakage which occurred in one of the cables in the Gulf of Bothnia, on the 13th December last. Thanks to the precautionary measure taken in 1883, when a third cable was laid across the gulf, as explained at the last general meeting of the Company, this interruption had caused no inconvenience, and they had been enabled to postpone the repairs of the same until the more propitious spring season. The shareholders would have observed from the monthly traffic returns which had from time to time been published, and from the profit and loss account which had been laid before them, that the net revenue had been larger than in 1883. This increase had not been due to the receipts on the Company's European lines, on which, on the contrary, there had been a diminution of traffic owing to the general stagnation of trade, but was exclusively attributable to the increase in the receipts derived from the Company's lines in the Far East. The receipts from the latter might have been considerably larger had it not been for certain stipulations contained in the French and Chinese concessions, in accordance with which some classes of Government messages, of which there had been a great number during the year owing to the war, had to be transmitted free of charge. Notwithstanding, or, perhaps, owing to, the political disturbances in China, the development of the inland telegraph system in that country had been actively progressing. The land line connecting Hankow, the great commercial centre in China, with the general inland system, had been completed, and after several intermediate stations had successively been established, the station at Hankow was opened for traffic on the 15th June last. On the 22nd August the first telegraph station had been opened at Peking, and no doubt the establishment of the telegraph in the capital had contributed largely towards the acceleration of the final peace negotiations between China and France. A new line had also been constructed in the north of China, connecting Newchwang and the new Chinese naval establishment at Port Arthur (Port Li). In the south of China a line had been constructed from Canton to the Tonkin frontier, and branching off to the important island of Hainan. As all these and other Chinese land lines could in a great measure be considered as feeding lines for the Company's cables, the Company had so far hailed their establishment with great satisfaction, although it had not from the very beginning been overlooked that the development of the Chinese land line system might sooner or later also prove competitive as regarded the Company's cable routes. A land line had, in fact, last year been opened between Foochow and Canton

Digitized by Google

as a continuation of the Chinese Shanghai-Foochow line, thus creating a competition with the Company's Shanghai-Amoy-Hong Kong local traffic. It was, however, confidently believed that the general development of the telegraph correspondence would not fail to counterbalance any threatening influence of some competitive land lines, and hitherto the financial results had not given rise to any serious apprehension. The telegraph field which the large commercial ports on the coast of China offer is so vast that there would be room enough for both cables and land lines. Meanwhile the Company had not lost sight of the fact that by the concession granted on the 8th June, 1881, the Chinese Government guaranteed the Company against such competition, and naturally the Company had immediately, when the same arose, remonstrated against the breach of this obligation. Up till now, however, only evasive answers had been received from the Chinese authorities, who appeared to meet certain difficulties in carrying out the engagements entered into by the Government. Considering that latterly grave political matters have engrossed the attention of the Chinese, it had not been deemed opportune at this present moment to press for an immediate favourable decision with regard to the Company's legitimate rights. In order, however, that the moderation thus shown by the Company should not be misunderstood, due notice of the infraction had been given, and in order to reserve their rights the Company had, fully agreeing in this measure with the Eastern Extension Telegraph Company, provisionally stopped the free transmission of the Chinese Government telegrams. Thus the matter stood at present, but the Company trusted that, when the political horizon in China had been cleared, the moment would arrive when the Government would find means to conciliate their own interests with the undoubted rights of the Company. Meanwhile, the Company were in possession of the opinion on this point of both eminent statesmen and legal authorities well versed not only in international law, but also well acquainted with Chinese institutions and customs, which opinions assured the Company of the perfect legality, even from a Chinese point of view, of their claims under the concession granted in 1881. With regard to other matters, the Chairman would only mention that the exchange of the old share warrants against new ones, referred to last year, had now been effected, and apparently to the satisfaction of everybody concerned. Also that the capital of the pension fund for the staff had been separately invested, and would therefore in future not figure in the balance-sheet. From the balance-sheet, which had already been placed before the shareholders, it would appear that after all the general charges, as well as the ordinary charges for interest and amortisation of debentures, and the payment of the usual 5 per cent. interim dividend during the past year had been provided for, there remained an amount of £135,504. 11s. 9d., which the Directors submitted to the meeting to deal with as follows:—£45,833. 6s. 8d. to be divided amongst the shareholders as an extra dividend of 3 per cent. (making the dividend for the year, including the interims already paid, 8 per cent.); £2,777. 15s. 7d. to be allotted to the pension fund for the staff; £55,555. 11s. 1d. to be added to the reserve and renewal fund; and £31,337. 18s. 5d. to be carried forward to next year's account. It was with much regret that the Chairman had to announce that the Company had again suffered a great loss by the death of two members of the Board of Directors, Mr. Julius Sick and Mr. Moritz G. Melchior. The former had been a member of the Board from the formation of the Company, and the latter joined the Board in 1874. Both had, by taking great interest in the Company, contributed considerably towards its ultimate success, and he was convinced that the shareholders would much regret their loss. To fill up the vacancies which had thus occurred, the Directors had asked C. St. A. Bille, Esq., late Minister for Denmark in the United States, and M. Melchior, Esq., to join the Board.

Without discussion the report was then unanimously adopted, the accounts were passed, and discharge given to the Board of Directors.

The retiring Director, the Chairman, C. F. Tietjen, Esq., was unanimously re-elected. The election of C. St. A. Bille, Esq., and M. Melchior, Esq., as members of the Board, was also unanimously confirmed; and A. Berner, Esq., and Aug. Garde, Esq., were re-elected as shareholders' auditors.

The West India and Panama Telegraph Company (Limited).

Report of the Directors, to be presented at the sixteenth ordinary general meeting of members:—

The Directors submit the accounts for the six months ending 31st December, 1884. The amount to credit of revenue is £40,983. 2s. 6d., and the expenses have been £26,047. 19s. 8d., leaving a balance of £14,935. 2s. 10d., which, with the balance of £3,933. 18s. brought from last account, makes a total of £18,869 0s. 10d. Of this sum the Directors have placed £8,000 to reserve, leaving an available balance of £10,869. 0s. 10d., with which it is proposed to deal as follows:—Payment of 6s. per share on account of arrears of dividend on the first preference shares £10,368. 18s.; balance to current half-year's account, £500. 2s. 10d. Total, £10,869. 0s. 10d. The traffic receipts show an increase of £535. 16s. 4d. over those of the corresponding period of last year. The Directors have much satisfaction in announcing that their long-continued efforts to effect the complete restoration of the original cable between Jamaica and Porto Rico have been successful—this important work having been accomplished on the 24th October last by the Company's ss. "Grappler. The line (700 knots in length) has since continued in good working order. By the re-establishment of this cable (which had been inoperative since 1874) the duplication of the most important section of the system is restored, and the colonies eastward of Jamaica have already realised the advantages of the duplication during two interruptions which have occurred since the repair was effected. The value of the cable expended during the half year on this restoration amounts to £6,917. 15s. 8d., which has been charged to the reserve account. The expenditure from first to last involved in the restoration amounts in the aggregate to £33,657, and this heavy outlay constitutes a further claim on the colonies which have not increased their subsidies beyond the original sums granted many years ago. At the time those grants were accepted it was contemplated both by the colonies and the Company that a single line of cables would secure the communication, which subsequent experience has proved to be a misapprehension. The colonies of Barbadoes, Guadeloupe, and Martinique have renewed their subsidies for further terms of years. The Company's appeal for a renewal of the St. Thomas subsidy, which expired on the 31st December last, is now under the consideration of the authorities of that colony. Several interruption to the cables occurred during the half year under report, and the Company's ships have been frequently employed in repairing operations. Since the repair of the Jamaica-Porto Rico cable, the ss. "Grappler" has been chiefly engaged in the examination of the original (duplicated) cable between Jamaica and Santiago de Cuba which has long been inoperative, but much difficulty has been experienced in the operations from time to time owing to the great depth of water and rocky ground. The ship is at present engaged on other repairs, but will return to this work when at liberty. The Company's second repairing ss., "Duchess of Marlborough," will shortly come to England to be refitted. On her return to the West Indies she will take out a further supply of new deep sea cable for repairing purposes. In accordance with the Articles of Association, Charles William Earle, Esq., and William Ford, Esq., retire at this meeting, and offer themselves for re-election. John George Griffiths, Esq., the auditor, also retires and offers himself for re-election.

THE INTERNATIONAL INVENTIONS EXHIBITION.

The progress made at the Exhibition during the past week has been very slow. The spurt put on to have an appearance of readiness at the opening ceremony seems to have used up all the energies of the exhibitors, and stands are still empty, or scantily furnished. Our criticisms upon this state of backwardness were a day or two since met very satisfactorily by one of our most energetic business men, whose firm is a large exhibitor. The answer to the state of unreadiness was so complete that we give it without compunction. "It is easy," says our authority, "to furnish a stand from articles in stock; but, as a rule, these are well known articles, and the Exhibition is intended for novelties. My exhibit is historically complete, because this portion was to hand, and needed little or no thought; but the novelties are not, and cannot in the nature of things be guaranteed to be ready to a day or a week. A machine of novel construction may have been completed weeks or months ago, but on trial found to require alterations here and there. This work of alteration takes time, and the satisfactory completion of an improved machine cannot be made to agree with a fixed date. We desire to send specimens of our latest and most improved machines," says the speaker, "machines which bear the stamp of 1885, and not those of previous years."

This desire, and consequently the backwardness, in many cases is allowable; but there are numbers of exhibitors who cannot be classed in the category of "exhibitors of novel machines." They are, and will be, merely advertisers of standard wares, examples of which could have been put together for exhibition any month within the last year; and yet their stands are empty. Deep, if not loud, rumours have reached us, though not with sufficient definitivness to enable us to speak positively, that some of the difficulties in the way of exhibitors have been caused by the absolute incapacity of certain members of the official staff. So far as the electrical exhibits are concerned, we shall be glad to receive any facts for or against official action, not necessarily for publication, but rather that the weak points of the system may be brought to light, placed before the proper authorities, and remedied. It must not be forgotten that even now the organisation of the 1886 Exhibition is under consideration, and if it is shown to absolute certainty that any members of the staff are incapable or inefficient they can and must be removed. Enough, however, of such rumours; let us proceed to facts. The electric light apparatus is still in such a chaotic state that we prefer the quieter walk through the East Arcade, where the electrical exhibits are supposed to exist. Entering from the vestibule we notice that Messrs. Crompton and Co. have a complete historic exhibition, showing the development of the several branches of their manufacture. This exhibit will be treated fully and illustrated in due course when complete, for the latest development has to come.

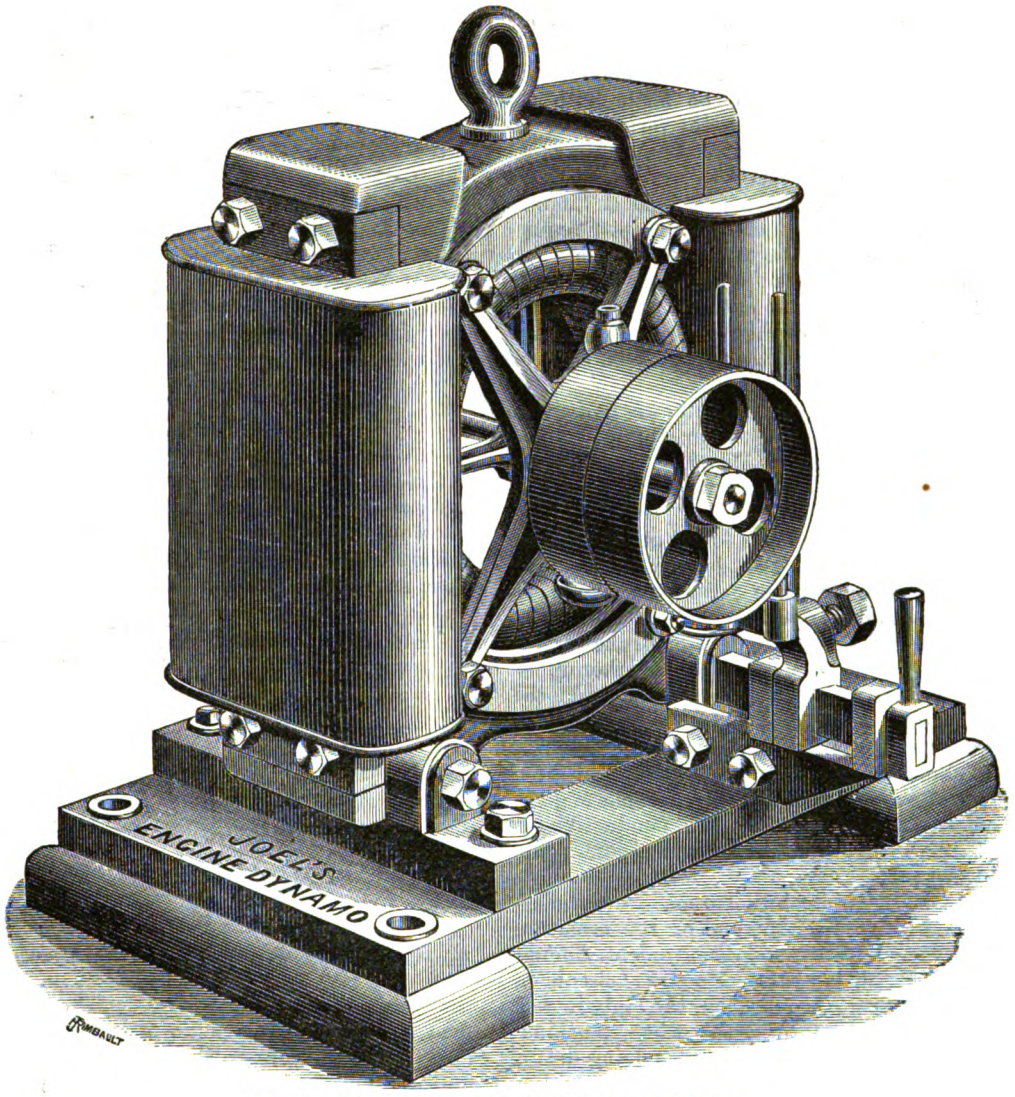

FIG. 1.—Joel's Combined Engine Dynamo and Motor.

Opposite to Messrs. Crompton's is a Crossley Otto gas engine, partially erected, and a stand which is also partially erected. Further on we come to the exhibits of Messrs. Woodhouse and Rawson, whose stand is perhaps the most complete in this part of the building. Messrs. Woodhouse and Rawson show

Digitized by Google

specimens of their numerous manufactures. A variety of incandescent lamps for various purposes are among the exhibits, some of the ordinary type for ordinary lighting, others with silvered backs for reflecting the light in given directions; others, and smaller lamps for surgical instruments and to apply to microscopes.

We have often referred to these lamps, and gradually the lapse of time allows us to have a better idea of the economy than can be obtained from theoretic reasoning. As is well known to our readers, Messrs. Woodhouse and Rawson claim that their lamps are very economical, but the question which has had to be decided, or rather which has to be decided—sufficient time has not yet elapsed to decide it—is that of the life of the lamps of great economy of current. From theoretic reasoning it can easily be seen that almost any given economy of current can be obtained, but we have long held that there must be a mean position between economy of current and length of life. That will ultimately be found, and it will be approached by all makers, so as to give an economical lamp. There is no doubt that, if the makers ultimately find a high-resistant lamp can be made with the same length of life as a low-resistant lamp, the former will be adopted, inasmuch as it would be an economical user of current. Besides the lamps, we have upon this stand a variety of minor appliances used for electric lighting purposes, such as holders, cut-outs, switches, terminals, &c. Some of these will require illustration, and will be referred to again. On the left and right again we come to almost vacant spaces, till the right-hand corner is reached, where some excellent specimens of Mather and Platt's workmanship are shown in the Edison and Swan United Company's exhibits of Edison-Hopkinson dynamo machines.

Coming now into the Arcade, on the left we notice the exhibits of H. F. Joel, who, among other things, shows, perhaps, the largest cell of a secondary battery that has yet been constructed; also his new dynamo, which, however, is not running.

Mr. Joel claims that the disadvantages found in other forms of electrical storage batteries have been overcome, and that this battery, the outcome of over three years' special experiments and trials, is thoroughly practical and reliable. The advantages claimed for it are :—The construction of the battery is mechanically efficient; the plates are clamped together under pressure, they cannot buckle or get out of shape, and the deploraising material cannot get out of place; the electrodes are independent of the outer case, and when not required for a length of time are easily taken out and thus preserved from local action; the special formation of the electrode plates gives them great storage capacity, and good electrical conductivity.

We are indebted to Mr. Joel for the following description of his dynamo :—

In most of the dynamo machines hitherto made the mechanical construction of the whole machine, and of the armature in particular, has been very defective and inconvenient. Should an armature become deranged, say through a short circuit in one of the coils, or from the ring slipping on the hub, it was impossible to repair it without returning the whole machine, or at least the armature, to the maker, thus involving delay, and for a time rendering the apparatus useless, and bringing the whole system into discredit. It was to remedy this defective mechanical construction that this dynamo was designed. During the last six years many experimental magnets and dynamo machines have been made, and many improvements introduced, the result being the dynamo machine here described.

The general construction of the machine is readily seen from the illustration Fig. 1. There are two vertical field magnets with very massive cores made of wrought iron, carefully chosen and annealed; these are bridged across at the top and bottom by heavy iron poles, moulded in selected cast iron. This form is considered to give the best magnetic field. It is a great point in this machine that there is plenty of iron of good quality in its construction, and the iron is so disposed that there is very little waste weight. The under faces of the poles have slots or grooves cast in them to break up eddy currents, and to accentuate the magnetic effect as much as possible at the centre of the poles. The coils are wound on a bobbin or sleeve, and can be easily taken off. Fig. 2 shows the complete armature, which is of the Pacinotti type; it is built up of sections or groups of laminated iron plates of segmental shape, which are punched or stamped with the tooth-shaped projection alternatively at one end out

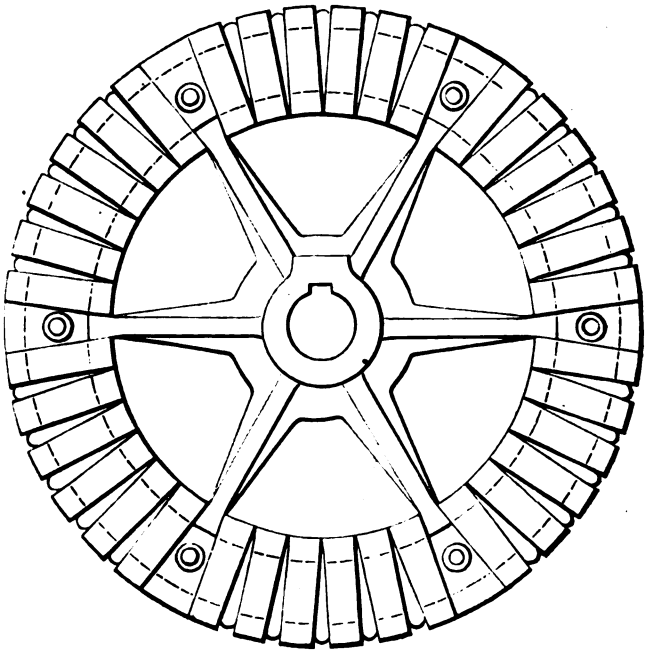

FIG. 2.—Diagram of Built-up Armature.

of the best Swedish iron (see Fig. 3). These thin plates are insulated from each other, except at the junction of the sections, where iron is pressed in contact with iron to form a series of continuous rings. The complete sections interlock and fit each other, and are fastened by bolts (also insulated) to the end of

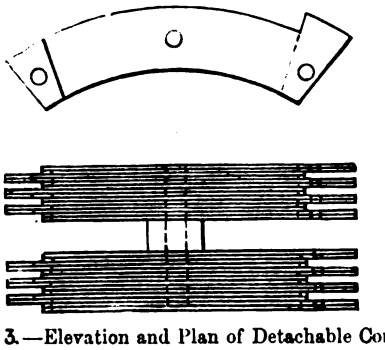

FIG. 3.—Elevation and Plan of Detachable Core Section.

spokes made of non-magnetic material, and thus form the rim of a wheel armature. With this construction the armature cannot slip or get out of place; it is rigidly fixed, not merely clamped as in some machines. The bolts are fixed parallel to the axle to prevent their loosening by centrifugal action. The

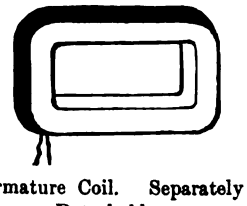

FIG. 4.—Armature Coil. Separately Wound Detachable.

insulated wire coils (see Fig. 4) are separately wound in a lathe or otherwise—this is a special feature of the invention—and are then threaded on the core sections. Should a coil become damaged the core section is taken out, and the coil slipped off and a new one quickly put in its place. The com-

Digitized by Google

mutator is fixed close to the armature, and the ends of the coils are connected in a special and convenient manner to the commutator; and, in order to facilitate the removal of any of the coils on the armature, they can be quickly connected or disconnected without soldering.

The brushes are supported on an adjustable frame, which is fitted on the end of the axle; the unscrewing of one milled hand nut allows the brushes and holder to be taken off, and the same nut clamps the brushes in any position. The movement allowed in the brush holder will enable, say, a 12-light arc machine to run only one or all the 12 lamps, or any intermediate number as desired. Special provision is made for holding the brushes off the commutator by an automatic locking device. This is very useful when working with gas engines. The axle is made of steel and is very short, the bearings are three to four times as long as the diameter of the axle, the bearing frame on the pulley side is made especially strong and braces the top and bottom poles and the whole machine rigidly together. The pulley bearing on the commutator side is of bracket form, and designed to allow the connections of the armature, and the commutator and brushes to be easily got at for cleaning, and also to give the utmost possible play to the brush holder. Special arrangements are made for lubricating the bearings and collecting the waste oil.

The "Engine Dynamo" is so named from its perfected mechanical construction, by machinery, in detachable pieces. Each part of the dynamo can be quickly and easily taken apart, and in case of necessity be repaired by the purchaser or user without returning the machine to the makers. This is useful on board ship and other places where an easily repaired machine is a necessity. The armature sections and coils, the field magnets, and every part are made to steel templates and gauges; they are interchangeable and can be replaced, and the engine dynamo is specially constructed to act either as a generator of electricity or as an engine-motor for driving machinery. The arrangement of the fast and loose pulleys and striking gear (see Fig. 1.) is very compact and strong. The adjustable base is also shown, and is very simple and easily attended to.

The advantages claimed by the inventor are:—The whole machine is built up of detachable parts, which are interchangeable. The armature, which in other dynamo machines is usually the weakest part, and exceedingly difficult to repair, is in the "Engine Dynamo" very simple and strong, and easily taken to pieces and put together again. The armature coils are separately wound to an exact size, and the insulation is more perfect. The peculiar construction of the armature core obviates the loss due to Foucault currents, and allows free ventilation. The coils on both the field magnets and armature can be changed as desired, and with the same iron frame many changes in the electrical output can be obtained. The brushes, commutator, oil feeds, and other parts are strong and convenient in construction. The machine takes up less room, and is stronger built than any other dynamo machine. Many tests of these machines have been made. A very interesting test was made by completely insulating the iron sections the one from the other by thin mica plates, to ascertain if the jointed construction affected the output; but, after careful trial, the tests showed that the insulation and disjointing made no difference in the result. A machine of this type, made and tested in 1882, showed a marked improvement over a Schukert machine of a slightly larger size and heavier weight. In this case the total weight of the machine was 2cwt. 1qr. 4lb. with 58lb. of copper wire on the armature and field; this gave at 1,200 revolutions per minute an effective current of 130 volts and 8 amperes. In a recent machine made by Messrs. Blakey and Emmott, electrical engineers, Halifax, Yorkshire, who are manufacturing these machines under licence from the inventor, the results were much better with only 6lb. of copper on the armature and 30lb. of copper on the fields; a current of 1,000 watts was obtained at a moderate speed. Still better results have been obtained by a slight modification of the resistances, and at a speed of about 1,200 three arc lamps can be worked from a machine whose bulk is contained in about 2 cubic feet, and whose total weight is only about 2cwt. From recent tests it is stated the commercial efficiency of the machines has been found to be nearly 80 per cent., whilst the conversion is over 90 per cent. Messrs. Blakey and Emmott have put down special tools in their large works for the manufacture of these dynamo machines of various sizes, and for all purposes, from a one arc light machine to a 500 incandescent light machine, and wound in series, shunt or compound.

One of the most forward of the exhibits in the East Arcade is that of Mr. Swan. Several electroliers of neat and chaste design are to be seen in these exhibits. We notice that the brass work of these electroliers has been made by Messrs. Faraday and Sons, of Berners-street, and by Messrs. Winfield and Co., of Birmingham. The cut glass ornaments are by Messrs. Osler. It may not be out of place here to refer to the exhibits of Messrs. Faraday and Son, which will be found just outside the East Arcade, in the new Eastern Avenue adjoining the Printing and Chinese courts. These exhibits comprise novelties adapted for electric lighting, and some especially adapted for domestic lighting. A switch in four sizes, which has been patented under the peculiar name of the "Pointsman," is said to have several good features, such as easy manipulation, immunity from imperfect contacts, and compactness. Various lamp-holders are shown, each supposed to possess a ready means of detachment, swing brackets, portable fittings, couplets and connections for flexible wires, electroliers, brackets, and standards of various designs. These, and many other fittings in brass, of excellent workmanship will be found at this stand. Besides the work referred to as the exhibits of Mr. Swan, specimens of this firm's manufacture will also be found on view. Messrs. Woodhouse and Rawson have also supplied the fittings used in the Prince of Wales's Pavilion, and in the East Quadrant dining room. Returning now to the exhibits of Mr. Swan, we may notice various examples of miners' lamps. One complete in itself carries in a small box underneath the lamp a secondary battery, which will supply current and feed a 2½ candle-power lamp for about four hours. Others are made to use with a reel of wire, which can be unwound, and the lamp supplied from a centre when placed in the position where it is required for work. For many months past we believe experiments have been going on to test the value of celluloid for the manufacture of the filament of incandescent lamps. This material is easily manipulated, and in a plastic state can be forced through gauges so as to obtain a perfectly regular and symmetrical filament of the material, which, of course, is always to be treated and carbonised. The specimens shown were excellent examples of perfect symmetry. Whether the material will prove in use to be as good as that at present employed we cannot say, but, if it does, troubles which arise from minute differences in cellularia in the material will be overcome. A number of small Swan lamps fitted for dental and surgical purposes are also shown, as are fairy and microscopic lamps. The use of these lamps for the latter purpose is gradually extending. We may be allowed to quote from a paper which appeared in the *British Medical Journal*, of January 27th, 1883, as to the value of the surgical electric lamps designed by Mr. Payne, and used by Dr. Thomas Oliver, M.R.C.P.:—

"Dr. Oliver had previously shown these lamps applied to microscopical and clinical purposes, and he obtained from Mr. Payne an instrument by means of which the throat could be illuminated and examined. He said that, having a patient in the infirmary who was suffering from hydatid disease of the liver, on whom the operation of abdominal section with incision of the liver had been performed, he took the opportunity, and succeeded in lighting up the interior of the cyst with the electric light by means of a similar instrument, but provided with an arrangement for cooling the lamp by circulation of water, designed by Mr. Payne for the purpose, and constructed by Mawson and Swan, of Newcastle. The apparatus consists of a brass tube, electro-plated, funnel-shaped at the outer end, and securely closed at the other end with a stout piece of glass. Down this tube is inserted a narrow cylinder, which carries the Swan lamp and the electric wires. The lamp is hermetically sealed in a glass shade, and water is conveyed to and fro through very small brass tubes, and is made to circulate round the lamp to carry off all heat. To

Digitized by Google

ensure perfect circulation of the water, as great a pressure as possible is obtained by having a tin can containing water suspended on a hook near the ceiling, and connected with the brass tube by lengths of india rubber tubing. The light from the lamp is perfectly pure, and shows things in their true and natural colour. The lamp is rendered incandescent by means of a battery of four modified Leclanché cells, which answers admirably for short periods." Dr. Oliver in his paper before the Northumberland and Durham Medical Society, said—"The tube, with its glazed extremity, was smeared with carbonised oil, although in future I shall use carbolised glycerine for the window of the tube, and with gentle pressure I succeeded in passing it through the abdominal incision into the interior of the liver. The lamp was at once lit, and by looking down the tube I had the satisfaction of observing a greyish-red condition of the walls of the cyst, studded across which were numerous yellow-white spots, evidently pus; a slight oozing or sweating was also noticed on the wall of the cavity. The illumination of the interior of the liver by means of the electric light was in every way satisfactory and successful, and although it is of little aid in the treatment of the case in question, it has shown us that the lighting up of internal cavities is not only a possibility, but a matter of comparative ease."

A large and increasing demand for the electric light is being made for its use at parties and balls, and it lends its aid to some very interesting and pretty effects in decoration. One such effect is shown in this exhibit by the placing of Swan lamps inside lemon peel. The wires are hidden by the leaves and stem of the plant, and when the connections are made, the decorations, which had previously seemed to be merely a mass of very dark green leaves, relieved by yellow globes, are beautifully illuminated. Such a system of decoration may be applied not only to fruit but to flowers, and we have seen lamps hidden among the leaves of artificial roses and other flowers which, when lighted, made a very pretty effect. Perhaps the newest piece of apparatus exhibited here is an electric meter, which cannot, however, be described without ample illustrations. The meter is for integrating time and current, and is adapted for electric lighting purposes. One of these meters has for a long time passed under trial, and has been found to work admirably.

A very interesting photo-mechanical process of printing, commonly known as "Woodburytype," is illustrated at Mr. Swan's stand by a number of specimens which have been supplied by the Woodbury Permanent Photographic Printing Company, of Ealing, W. The new system of printing consists in a combination of the principle upon which intaglio or copper-plate printing is based, and that upon which the image in carbon printing is obtained. An image, in which the shadows are in relief and the whites depressed, is obtained by exposing bichromated gelatine under a suitable cliche to the action of light, and afterwards to water. The details of the process may be varied, but we need not enter into them here, as the principle is well known. From the gelatine an electrotype is obtained with the lights in relief, and the shadows depressed, as in an engraved copper plate. This is the block or cliche from which impressions have now to be obtained by mechanical means. It must be borne in mind that the intaglio so obtained represents by degrees of depth the gradations of the image. This intaglio is now to be filled with a thick solution of gelatine, containing indian ink, or other colouring matter mixed with it; when slightly set, and the surface cleaned, as in copper plate printing, it is placed in contact with paper, the surface of which would be best prepared with gelatine, albumen, or collodion, to prevent it being absorbent; the block is then brought into firm contact by steady heavy pressure. The set gelatine and colour will be thus delivered on to the paper, much in the same way that the cook delivers a shape of jelly from its mould. The gelatine and colour so delivered on the paper will in all respects resemble a carbon print. The deepest shadows will consist of a thick opaque layer forming black, each gradation from these to white consisting of a thinner layer of the translucent material. This is really a development of the carbon printing process invented by Joseph Wilson Swan in 1864, by which the effect of light and shade on a photograph is obtained by a coating of gelatine, coloured with carbon, and rendered sensitive to light by bichromate of potash, and which is rendered insoluble, by exposure to light under a negative, to varying depths corresponding to the varying degrees of transparency in different parts of the negative, the stratum not affected by the light being afterwards washed away. Mr. Swan proposed that the intaglios from which the prints or castings were made should be produced from the gelatine relief by the electrotype process. This method of producing the intaglio mould was subsequently modified by Mr. Woodbury, who found it advantageous to employ a lead plate, on the surface of which a reverse of the gelatine relief was obtained by means of hydraulic pressure. A specimen of an electrotype intaglio, and also of an intaglio produced on lead by pressure are shown. The most interesting feature of the process is the peculiar method of printing employed—a sort of cross between printing and casting—and which is as distinct from other methods of printing as lithography is distinct from letterpress. The following particulars will make clear how the printing from lead or electrotype intaglio is effected:—A warm solution of gelatine, coloured, as in the carbon process, with carbon or other pigments, is poured upon the centre of the intaglio, and a sheet of very smooth paper, backed by a perfectly true plane surface of metal, is brought down upon it, so as to expel the superfluous gelatine solution from between the paper and the surface of the intaglio and leave the depressions filled. After allowing the gelatine solution (which may be termed the ink) to completely set, the paper is lifted off and carries with it the solidified gelatine casting, a perfect counterpart of the intaglio. The print is then immersed in a solution of alum, which renders it insoluble. The result is that, as the coloured gelatine solution or ink is semi-transparent, those parts of the print which correspond to the deeper parts of the intaglio will be darker in tint than where the stratum of gelatine is thinner.

On the opposite side of the Arcade we note perhaps the most complete of all the exhibits, that of Messrs. Davis and Timmins, who show an excellent assortment of their manufacture in brass screws. Terminals of all sorts and all sizes are to be seen here, as well as specimens of wire used for electrical purposes. Mr. Meyer, of Liverpool, shows specimens of his system of laying underground wires for lighting, telegraphic, and other purposes. Close by is also the exhibit of the Kinetic Engineering Company, showing specimens of the Berthoud-Borel system of electric cables. We have so often referred to these that it is impossible to say anything new about them.

The Electrical Power Storage Company, whose exhibit, however, is not yet complete, have some fine examples of their most recent form of cells. There is no doubt but that every improvement added to secondary batteries brings us nearer to the time when they will become altogether reliable, and take their proper position in every electric light installation. The principal improvements are necessarily in the details relating to the form of the plate, the connections, and the containing cell. From impartial users of the most recent forms we hear that the improvements are real. Other exhibitors of storage batteries are the Consolidated Electric Company, whose batteries on the B. T. K. system are also used in the lighting of the tunnel, the current for charging the batteries being supplied by Messrs. Goolden and Trotter from one of their Halifax machines, under the supervision of Mr. Beeman. Mr. Planté, again, has an exhibit, which as yet has proved one of the most attractive in the Arcade. It is ready—and an attendant is there to explain fluently and simply the apparatus shown.

One of the largest, most important, and most complete of the exhibits is that of Messrs. Laing, Wharton, and Down; and fuller reference will hereafter be made to this exhibit, including as it does the apparatus connected with the Thomson-Houston system of lighting.

The Vulcan Manufacturing Company show specimens of their work, which is devoted principally to the construction of all that pertains to electric bells. A large variety of portable bells, of pushes, connections for house, ship, and public work, are on view. The workmanship, so far as we have been able to examine it, is excellent.

NOTES.

THE ELECTRIC LIGHT IN BELGIUM.—The offices of our contemporary, the *Moniteur Belge*, are to be lighted electrically.

THE HOTEL METROPOLE.—In this hotel about 70 miles of electric and bell wire have been used to connect up the various rooms.

ELECTRIC LIGHTING.—Tenders for the lighting of the town of Dundalk by electricity are invited in our advertisement columns.

NEW INSULATING MATERIAL.—It is said that MM. Berthoud and Borel are preparing a new insulating substance into which boiled linseed oil enters largely.

THE REDON ELECTRICAL BELL.—The electrical bell of M. Redon, lately exhibited at the Observatory in Paris, is an improvement upon the apparatus in common use.

THE TELEGRAPH IN ALGERIA.—The financial position of the Algerian telegraph is a prosperous one; the receipts having been augmented of late in a remarkable manner.

THE NEW ORLEANS EXHIBITION.—A Reuter's telegram, dated New Orleans, May 20, says the New Orleans Exhibition will be closed on the 31st inst., but will reopen in November next.

A NOVEL APPLICATION OF POWER.—A small Guimaraes motor, worked by a primary battery, has been ordered by an enterprising American for the purpose of hoisting a letter box four stories.

THE MANUFACTURE OF BICHROMATE OF SODA.—The manufacture of bichromate of soda as a substitute for bichromate of potash in primary batteries is being actively carried out by M. C. S. Sorman.

THE B.T.K. SYSTEM.—A merchant writing from Colchester to the Consolidated Electric Company expresses his satisfaction with the electric light which has been in use in his offices for about eight months.

THE INVENTORIES.—The continuation of our report of the Exhibition is postponed to our next issue in the hope that the arrangement of the electrical exhibits will have approached completion by that time.

EFFECTS OF LIGHTNING IN FRANCE.—The number of persons killed by lightning in France since 1835 is 4,609. During 30 years, that is to say, since 1854, 2,222 men and 929 women have been destroyed.

THE ELECTRIC LIGHT AT BANGOR, ME.—The city of Bangor, Me., is now lighted by the Thomson-Houston system, the plant having been put in by the American Company of Boston. The present capacity is 114 arc lights.

SOCIEDAD ELECTRICA.—Under the above title a society has been constituted in Barcelona by D. Narciso Xifra, an engineer, for the construction, installation, and maintenance of the most modern forms of electric light and other apparatus.

THE GIME ACCUMULATOR.—The sole advantage seemingly possessed by the new accumulator of M. Gimé is that the plates when used can be removed with greater facility than is usual with the ordinary types of secondary batteries.

THE VAN RYSSELBERGHE SYSTEM.—Induction has been giving so much trouble in Switzerland, that the administration of the telegraphs of the Confederation have decided to adopt the Van Rysselberghe system between Lausanne and Geneva.

NOTICE OF REPAIR.—The Eastern Telegraph Company announce the repair of the Eastern and South African Company's Zanzibar-Mozambique cable, thus re-establishing telegraphic communication with the East Coast of Africa, Natal, and the Cape of Good Hope.

THE ELECTRIC LIGHT IN CHICAGO.—Both incandescent and arc electric lights will be used in the New Chicago Board of Trade Building, and the light plant in the basement is a valuable one. The main hall is lighted by four large sun burners and twenty arc lights extending around the hall.

THE SOUDAN TELEGRAPHS.—The Cairo correspondent of the *Daily Telegraph* says:—The greatest regret is expressed here at the decision to refer the settlement of the dispute about the payment for the military use of the Soudan telegraphs to arbitration, and it is considered that an exhibition of vigour by England would be very opportune.

FASTNET SIGNAL AND TELEGRAPH STATION.—The laying of the submarine cable connecting Lloyd's signal station on the Fastnet Rock with the mainland at Crookhaven has been successfully accomplished. Vessels which pass this station and wish to be reported can now be signalled and reported by telegraph direct from the signal station on the Rock.

ELECTRIC LIGHTING OF TRAINS.—The Lancashire and Yorkshire Railway Company are trying the experiment of lighting the express trains between Manchester and Liverpool, Leeds, Bradford, and York, by means of electricity. The system has been in operation two or three days, and has proved very satisfactory. The lamps used are those of Woodhouse and Rawson of 10 candle-power.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, on Thursday, 28th inst., when the following papers will be read:—"On Ship Lighting by Glow Lamps, Embodying Results of Trial for Economy in H.M.S. 'Colossus,'" by B. J. Farquharson, member; "Electric Lighting at the Forth Bridge Works," by J. N. Shoolbred, B.A., M. Inst. C.E., member.

A GOOD OPPORTUNITY.—An announcement will be found in our advertisement columns to the effect that a gas company in a small borough in the midland counties is charging four shillings per 1,000ft. for gas as supplied to public lamps, and four shillings and sixpence to private consumers. Every assistance and facility would be given to a company which could supply the electric light to the whole or the principal part of the borough at a less cost than that now paid for gas. Come on, electric light companies!

THE SOUDAN MILITARY TELEGRAPH.—The line of military telegraph between Cairo and Korti, 1,123 miles in length, seems to be both efficiently worked and maintained. The principal stations are Cairo, Assiout, Assouan, Korosko, Halfa, Dal, Dongola, Debbeh, and Korti, while branch stations have been opened at Shellal, Gemai, Serras, Mohrit, Ambigole, Akasha, Abu Fatmeh, and Merawi. Between Assiout and Assouan, a distance of 320 miles, translaters are in use, and these are worked with about 30 volts, a fact which speaks well for the insulation of the line.

THE ELECTRIC LIGHT IN MINES.—The installation in the lead mines of Mechernich, Eifel, is giving great satisfaction. The space lighted is about 650 metres in length by 340 in breadth, and 104 in depth, and this is accomplished by means of two Siemens arc lamps of 3,000 candle-power each. The total cost of the installation has been £550, which includes

Digitized by Google

also 10 arc lamps of 350 candle-power each in the galleries, while the cost of the light per hour is said to be 1s. 11d. as against 2s. 6d. for oil, &c. Another installation of nine Siemens lamps is in course of projection.

THE FAWCETT MEMORIAL FUND.—The sum collected towards the fund for the national memorial to the late Postmaster-General by the servants of the Post Office now amounts to £918. 3s. 8d. At the influential meeting presided over by the Lord Mayor on Wednesday it was decided that the national memorial should take the form of (1) a tablet in Westminster Abbey; (2) a scholarship tenable by a blind person at any university, including women's colleges; (3) the promotion of the higher education of the blind in connection with the Royal Normal College and Academy of Music at Upper Norwood.

DOMESTIC ELECTRIC LIGHTING.—On Tuesday evening last, May 19, Mr. F. Geere Howard, of Cleveland-street, W., lighted up a greater part of Mrs. Robert Smith's house in Dover-street, Piccadilly, on the occasion of a ball given that evening. The ball room, supper room, and three other rooms, besides the vestibules, passages, &c., were entirely lighted with incandescent lamps, shaded with ground opal and pink glasses. In all 39 Swan lamps of 20 candle-power each were used, the current being obtained from fifty 1 horse-power accumulators supplied by the Electrical Power Storage Company. The cells were left in their van in the coach house belonging to the house.

ELECTRICAL NOTATION AND NOMENCLATURE.—The system introduced by M. Hospitalier at the last meeting of the Society of Telegraph-Engineers and Electricians commends itself to us generally, but it is to be hoped that among other things the symbols C for *current* and Cp for *capacity* will finally be adopted. The French I, representing *intensity*, does not sufficiently convey the idea of *current*, and it is liable furthermore to lose itself on a long equation where arithmetical unity occurs with any frequence. K, as symbolical of *capacity*, is objectionable in that the Greek κ is almost universally used for coefficient. This question, however, is treated at length in another part of our present issue.

THE ELECTRIC LIGHT IN NEW YORK.—The New York Gas Commission have awarded the following contracts for lighting the streets:—The United States Illuminating Company, lighting with electric light the streets and parks now lighted by said company and the following in addition: Catherine-street (from Chatham-square to the East River), Chambers-street (from Broadway to the North River), Fulton-street (from the North to the East River), and Canal-street (from Bowery to the North River), at 70 cents per night for each lamp; the Brush Electric Illuminating Company for lighting by electric lights the streets and lamps now lighted by said company at 70 cents per night for each lamp; the Equitable, the Mutual, and the Central, the Northern and the Yonkers Gas Light Companies for all the streets on their mains except those lighted by electric lights.

THE ELECTRIC LIGHT IN PARIS.—*Apropos* of the installation at M. Boudet's shop in the Boulevard des Capucines in Paris, mentioned in our issue of May 9th, the Société le Chrome inform us that after some experiments upon a dozen lamps it was decided to light the whole of the shops on the ground floor with 72 lamps, and this installation was put down and started on the 20th ultimo. The lamps are Woodhouse and Rawson of 40 volts, and are arranged three in series and six in multiple arc, making four groups of 18 lamps. These are fed by four primary batteries of 100 cells, each containing chromic acid manufactured at the works of the Société le Chrome at St. Ouen from ore from New Caledonia. As chromic acid does not attack zinc when the battery is not in action the zincs are left in the liquid. As regards the price it is said to be very little over that charged in Paris for gas. It is proposed, we believe, to add a number of large Gramme regulators to this installation, and in September next to extend the number of lamps to 300.

NEW TELEPHONE COMPANY.—A circular is about to be issued by this company calling attention to Prof. Silvanus P. Thompson's patent telephones now manufactured by them. In the transmitting instrument the use of a tympanum to catch the sound of the speaker's voice is obviated by the employment of a funnel-shaped tube; and instead of the tension regulator or carbon-button used by Edison, there is a metallic ball-valve. This combination of a speaking tube with a ball-valve to control the electric current is one of the most novel points of the new invention, and is as simple as it is novel. In the receiving instrument at present used by the New Telephone Company the vibrating diaphragm consists of a piece of gold-beater's skin properly prepared, carrying at its centre a bit of thin iron about as big as a thumb nail; this is placed in front of an electro-magnet, which is excited by a current from a battery in the line wire. The price fixed for the two complete sets of instruments required for the two ends of the line is a moderate one.

TELEGRAPH ACTS AMENDMENT BILL.—On Tuesday evening Lord J. Manners said that this Bill was down for Friday, but he would like the second reading postponed until after Whitsuntide.—Mr. Shaw-Lefevre did not understand that the noble lord was opposed to the second reading, but objected to some of the details. If the Bill was to come into operation in August next, it was necessary that the second reading should be passed before Whitsuntide, otherwise it would be impossible to make the arrangements for the sixpenny telegrams. He suggested that the noble lord should allow the second reading to be taken on Friday, and that the discussion should be postponed until the Committee stage.—Lord J. Manners subsequently said that he had no alternative but to accede to the suggestion of the right hon. gentleman, and he therefore gave notice that he should postpone his amendment till the Committee stage.—A morning sitting for the second reading of the Sixpenny Telegrams Bill will accordingly be held this day (Friday), the House adjourning at 7 o'clock for the holidays.

A NEW COMPETITOR FOR THE ELECTRIC LIGHT.—On Wednesday evening at the invitation of Mr. Alfred Ridsdale, of the Minories, London, a number of gentlemen assembled at the Criterion to inspect a new system of railway carriage illumination by means of Shallis and Thomas's patent mineral oil roof lamps for oils from 120° to 250° flashing point. The advantages claimed for the new lamp are substantially as follow:—Absence of shadow; perfect steadiness of light at whatever speed the train be running; ventilating properties; brilliant power of light; and economy, in that in comparison with the lamps ordinarily in use for railway carriage lighting a saving of 70 per cent. is effected in cotton waste for cleaning purposes, of 150 per cent. in cotton wicks, of 65 per cent. in oil, and of 60 per cent. in repairs. The light as we saw it on Wednesday evening was a marked improvement upon that common to public vehicles, and was certainly very steady. Altogether we must congratulate the inventors of the new system upon the result of their labours.

GAS VERSUS ELECTRICITY IN NEW YORK.—The Secretary of the Gas Commission has reported to the City of New York regarding the relative cost of gas and electricity for lighting

Digitized by Google

streets. The city has 647 electric lights, costing annually £33,061. 14s. These displaced 3,016 gas lamps, costing £10,556. The Common Council has requested that 2,093 additional electric lights be put in use, displacing 5,345 gas lamps. The cost of these electric lights will be £106,952. 6s. a year, while the gas lamps over the same area cost £18,707. 10s. Should the additional electric lights be authorised, there will be on Manhattan Island 2,740 electric lights, costing £140,014, and 13,685 gas lamps, costing £46,597. 6s. As the cost of lighting the Twenty-third and Twenty-fourth wards is £23,526, the entire cost of lighting the city would be £210,137. 6s. This is one way of putting the cost, electric lamp *versus* gas lamp! The advocates of gas take good care to withhold all discussion as to areas efficiently illuminated, and make no mention of the respective number of candles given in each case.

Lord Salisbury on the Electric Lighting Industry.—In the course of his speech, on the occasion of the annual dinner of the Middlesex Conservative Association on Wednesday last, Lord Salisbury made the following remarks:—"Mr. Chamberlain is not the originator of the idea of ransom. There are picturesque persons, travellers will remember, in Sicily and Greece, who are very familiar with the word 'ransom,' but they are not supposed to exercise a beneficent influence upon the lands they condescend to occupy. Mr. Chamberlain has had under his hand a certain industry—electric lighting. He was not willing to give them free scope, but he thought he could get a ransom, and he desired that at the end of twenty-one years any enterprise these electric lighting companies might set up should be confiscated for the benefit of the municipality in which they acted. This shows you how this plan of exacting ransom has answered. Bankruptcy has followed, I believe, nearly every one of these companies, and what is, in America, marching on with giant strides and contributing to the comfort of the people is here entirely strangled."

The Telephone in Berlin.—The *Pall Mall Gazette* says:—"The development of the telephone in the hands of the German Post Office is a further witness to the better side of paternal government. The telephone has been largely taken advantage of for private communication between offices, warehouses, and private residences, but the main use of it is in connection with the Exchange. Berlin has an Exchange with over 2,500 members. There are offices at the Central Telegraph Office, Oranienburger Strasse, Unter den Linden, Halle Gate, Köpnicker Strasse, and Central Market. At these offices a numbered list of the members may be seen, this list being also supplied by the Post Office to each member and the additions periodically intimated. Any one desiring to speak to a member may enter an office and request to be put in communication with Number So and-so. The fee for this is 50 pfennig, and the time allowed is five minutes. This time, however, is not strictly observed, unless a second person is waiting to speak with the same member. When the conversation is finished a bell is rung at the central office. This, indeed, is a popularising of the telephone, which not only citizens, but visitors to Berlin who take the trouble to familiarise themselves with the Post Office arrangements, may employ to the great saving of time and trouble."

Combined Arc and Incandescent Lighting.—Having regard to our remarks on this subject in our last issue, the *Tecnomasio Italiano* of Milan write to inform us that since the month of November, 1884, the steamboat "Regina Margherita," belonging to the firm of Rocco, Piaggio, and Sons, of Genova, has been successfully and efficiently lighted by a combined system of 100 16 candle-power incandescent and 4 arc lamps, the latter being placed in multiple arc with the incandescents, and regulated by a series of resistances. These lamps are all served by a machine manufactured by our informants. The same system was employed by the *Tecnomasio Italiano* during the winter of 1884 for the illumination by arc lamps of the theatre of La Scala at Milan. In this installation the dynamo served at the same time eight arc lamps in multiple arc, and a certain number of incandescent lamps of 100 volts. The difference of potential in this case was reduced by means of the resistance furnished by the 100-volt lamps, of which the number varied according to the intensity of the arc it was wished to form. When the carbons were in contact the incandescent lamps were at 100 volts, but as soon as the carbons were parted they fell to an incandescence corresponding to about 50 volts. In point of fact the resistance of each circuit remained constant, whether the arc was formed or not. With this system, when an arc had to be extinguished for the requirements of the service, by approaching the carbon to a point of contact, the other arcs which remained in action experienced no variation whatever by reason of the incandescent lamps acting automatically as resistances, and the quantity of current passing in any portion of the circuit underwent, practically speaking, no perceptible alteration. We are further informed that the above arrangement is due to Mr. Emilio Cabella, a young electrician of Milan. The installation at La Scala Theatre has given such satisfaction that the management have decided upon the final adoption of the electric light.

Salvage by a Telegraph Steamer.—Valuable salvage services have been rendered by the telegraph cable steamship "Minia," belonging to the Anglo-American Telegraph Company, to the barque "Hudson," her cargo and freight, in the Atlantic Ocean, in April last. On the 28th of March the "Minia" left Halifax, Nova Scotia, for the purpose of repairing the Brest-Saint Pierre cable, which had been broken about lat. 48.34 north, and long. 11 west; she had about eighty miles of telegraph cable, besides other telegraphic appliances, and was manned by a crew of eighty-five hands. The weather was very tempestuous during the voyage, and on the 8th of April, when the "Minia" was in lat. 46 4 north, and long. 14 26 west, a dismasted barque, which proved to be the "Hudson," was sighted about seven miles off, flying signals of distress. The course of the "Minia" was altered, and having approached the "Hudson" it was ascertained that she was 145 days out from Java, bound for Falmouth with a cargo of sugar. Her main and mizen masts had been carried away close to the deck, her foretopmasts had gone at the cap, and she had suffered other serious damage. At first the master of the "Minia" declined to take the "Hudson" in tow, on account of the urgency of the business on which he was engaged, though he offered to take off her crew; but eventually, at the earnest solicitation of the master of the "Hudson," he agreed to make an attempt to save the barque. Hawsers were then passed between the two vessels, and the "Minia" commenced to tow the "Hudson" towards Falmouth at slow speed. On the following day the wind increased, and additional hawsers were made fast as a precaution. The towage continued at varying speeds until about 5:30 p.m. on the 12th April, when the "Minia" brought the "Hudson" in safety into Falmouth, having towed her a distance of 490 miles. The value of the "Hudson," her cargo, and freight was £17,685. The sailors have been awarded £1,500, apportioned as follows:—£900 to the owners of the "Minia," £200 to the captain, and £400 to the crew.

THE ELECTRIC LIGHT FOR WAR SHIPS.—The Italian cruiser, "Giovanni Bausan," built and armed by Sir W. G. Armstrong, Mitchell, and Co., Newcastle-on-Tyne, and commanded by His Royal Highness the Duke of Genoa, left the Tyne, on her official speed trial, on the 11th inst., and during a prolonged trip of over six hours maintained her exceedingly high mean speed of over 17½ knots per hour. The vessel, which with her powerful armament of Armstrong guns and Whitehead torpedos is probably the most redoubtable cruiser in the world, is fitted throughout with the electric light. Two Gramme dynamos, driven by Brotherhood three-cylinder engines, supply the required electric current, and together with 32 one horse-power electric accumulators, manufactured expressly for ship use by the Electric Power Storage Company, and enclosed in teak boxes, instead of the usual glass cells, are placed in the after torpedo chamber, where is also fitted a switch-board controlling the nine distinct circuits into which the lamps (arc and incandescent) are divided. The incandescent light circuits are as follow :—

Passages, deck houses, and captain's cabins	43
Cabins and mess rooms	44
Coal bunkers	18
Engine room	20
Stoke holds, fan rooms, and hydraulic engine room	28
Torpedo room	6
Magazines and steering gear	11

which, with six pilot lamps in the electric engine room, make up a total of 176 lamps, all of which are of the Edison eight candle-power, 51 volt pattern. Each cabin has one or more lamps, and these are throughout fitted with individual switches. The separate circuits are distinct, and can be controlled direct from the switch-board. The ship is also fitted with two search arc lights of 20,000 candle-power placed on the forward and after gun loading stations respectively. The ordinary practice on board is to start the dynamos to charge the accumulators during the afternoon, keeping them running during the evening until the cabin lamp circuit is switched off, when the dynamos are stopped, and the accumulators serve to maintain the passage lamps throughout the night. The accumulators are also employed to maintain a portion of the incandescent lamps when the dynamos are feeding the search lights, and are, moreover, a very useful reserve in case of any accident to engines or dynamos, or when only one or two lamps are required. The wires, which are fitted upon the double return wire system, are enclosed throughout in grooved teak or pine casing. The entire fitting up of the installation has been performed by the builders, Messrs. Sir W. G. Armstrong, Mitchell, and Co. The vessel is expected to leave for Italy in a few days.

SIXPENNY TELEGRAMS.—Extensive preparations are being made by the Post Office Authorities for the new system of sixpenny telegrams. The extensions have been made on the basis of an estimate that the reduction in tariff will cause an increase of the business of the department to the extent of 30 per cent. within the first year, and the extra expenditure already incurred amounts to half a million sterling. Of this amount £475,000 has been spent on new plant—poles, wires, instruments, &c., whilst £25,000 has been laid out in the erection of new buildings. This comparatively small proportion for the latter purpose is due to the fact that accommodation for future development had already been provided in most of the post offices built or extended within the last two or three years, including those at London, Manchester, Bradford, York, Exeter, and Plymouth, Glasgow and Aberdeen, Cardiff, Dublin, Belfast, and Cork. The length of public road upon which new poles have been erected in England is 850 miles, apart from the extension on railway routes, and upon these poles there have been placed 9,200 miles of new wires, in addition to which there are about 11,600 miles of new wires put up on existing road or railway poles. Three new trunk lines have been formed, the first from London *viâ* Peterborough, Doncaster, York, and Pierce Bridge (Darlington), to Newcastle; the second from London, *viâ* Aylesbury, Widnes, Leamington, then north of Birmingham to the west of Chester, half-way between Liverpool and Manchester, through Wigan, and then by way of Lancaster to Carlisle; the third, over the South Western line to Basingstoke, through Andover and Salisbury to Exeter—each with branches at various points from the main circuits. Similar extensions on a somewhat smaller scale have been made in Scotland and Ireland. A number of new three-wire submarine cables, for service under channels, rivers, and lakes, have also been provided for the convenience of the Isle of Man and the Orkney and Shetland Islands. In London the number of offices at which the pressure of business is met by the use of pneumatic tubes, will be increased by the use of an additional length of 7,500 yards of tube. Among the additional instruments purchased are 40 Wheatstone automatic, eight quadruplex, 300 duplex sounders, 350 single sounders, 150 single needle machines, and 10 extra repeaters. The duplex system will be completed in the case of 100 circuits. The staff throughout the kingdom will be increased to the extent of 1,200 new telegraphists and over 1,000 messengers.

SIR W. THOMSON AND MAXWELL'S ELECTRO-MAGNETIC THEORY OF LIGHT.—From a letter written to *Nature*, by Prof. G. F. Fitzgerald, on the subject of the electro-magnetic theory of light, we extract the following:—"Sir William Thomson has clearly pointed out a direction in which to look for a true wave-propagation. It will make his position clearer, and also Maxwell's, to use his analogy between water in an elastic tube and a conductor of electricity. I will suppose the water contained in a tube bored out of a very large lump of india rubber. He enumerates three electric qualities concerned, and their hydrodynamic analogues:—(1) 'Charge' or electrical accumulation in a conductor subjected in any way to the process of electrification. (2) 'Electro-magnetic induction' or electromotive force excited in a conductor by variations of electric current. (3) Resistance to conduction through a solid. The hydrodynamic analogues are:—(1) Accumulation of a greater or less quantity of water in any part of the canal or tube. (2) Inertia of the water. (3) Viscosity or fluid friction. He explains that a true wave-propagation arises from the compressibility of the water, combined with its inertia, and that if the tube be elastic, like india rubber, there would also arise a wave-propagation. 'Accordingly,' he says, 'a definite velocity of propagation of electric impulses, depending on the inertia and the capacity for charge, is to be looked for, as has been done in a first article, published by Kirchhoff, on the subject.' Now, in all this discussion Sir William Thomson omits to mention the only thing that is at all analogous to Maxwell's propagation of wave disturbances in non-conductors, and it arises from his considering the water as contained in a tube like ordinary india rubber tubes, instead of in a tube bored in an indefinitely large lump of india rubber. If we consider this case it is evident that one of the conditions to be considered is the propagation of waves in this lump of india rubber. In Sir William Thomson's tube there would of course be a velocity of wave-propagation in the india rubber, but that is a very different matter from the propagation of disturbances away from the neighbourhood of the tube by which energy would be carried away from it. To do this Sir William

Digitized by Google

Thomson should have included the propagation of sound in the air or whatever he supposed surrounded the outside of his tube. Without including this, he was not including anything a bit analogous to Maxwell's electro-magnetic theory of light. In Sir William Thomson's tube the whole state of affairs at any time could be expressed in terms of variables that represented bodies near the tube, while in the other case it would be absolutely necessary to introduce variables representing every part of the india rubber which I have supposed of indefinite extent. This is just the difference between Sir William Thomson's and Maxwell's views. According to Maxwell's view there is a great deal more going on outside the conductor than inside it, and it is evident that the inertia of the water is a very bad analogue to electro-magnetic induction, for this latter depends essentially upon the form of the circuit, and not only upon its section and length. Maxwell has shown that light may be a wave-propagation of what are on his theory *analogous*, though probably utterly *unlike* the distorsional waves propagated in the india rubber, and has shown that a medium which would only transmit disturbances analogous to these would explain electric and magnetic phenomena. It is to be remembered that Maxwell's theory gets rid of all action at a distance, and that the only *experimentum crucis* between theories of action at a distance and of action through a medium is that in this latter case the energy may be propagated in time through the medium, while in the former it cannot. Sir William Thomson's speaking of the ether as *like* a jelly must be strongly protested against. It is in some respects *analogous* to one, but we certainly know a great deal too little about it to say that it is *like* one. May be Maxwell's conceptions as to its structure are not very definite, but neither are any body's as to the actual structure of a jelly, and there is no real difficulty in supposing a medium whose condition is represented by symbols that obey the laws that Maxwell has shown should be the laws of symbols representing the condition of a medium that would explain electric and magnetic phenomena. It seems very unlikely that any jelly is at all *like* the ether that Maxwell supposes. It seems much more likely that what he 'called electric displacements' are changes in structure of the elements of the ether, and not actual displacements of the elements. He guards against this being supposed a necessary part of his theory when he defines polarisation in terms that certainly require a change of structure rather than a change of position, so that I think the word 'displacement' was unfortunately chosen. I also think that Sir William Thomson, notwithstanding his guarded statements on the subject, is lending his overwhelming authority to a view of the ether which is not justified by our present knowledge, and which may lead to the same unfortunate results in delaying the progress of science as arose from Sir Isaac Newton's equally guarded advocacy of the corpuscular theory of optics."

THE ELECTRIC LIGHT IN THE "IRISH TIMES" OFFICE.—At a meeting of the Royal Dublin Society held on the evening of the 18th inst., under the presidency of Mr. Howard Grubb, F.R.S., Mr. J. A. Fahie, C.E., read a paper on "Notes on a Year's Working of an Electric Light Installation," from which we extract the following:—"The following notes of twelve months' actual working of an electric light installation will doubtless be of interest. The installation here referred to is that at the offices of the *Irish Times*, which was fitted up in January, 1884, so that a year's working was completed in January last. The dynamo-electric machinery consists of a Siemens alternate-current machine, and a shunt wound continuous-current machine as exciter. These machines are capable of feeding 150 incandescent lamps at a brilliancy of about 17 candles each. The lamps used are of the Swan type, arranged in parallel circuit, and fixed to the gas fittings wherever practicable. The motive power is derived from two gas engines of the Crossley type, which are coupled up to a counter-shaft from which the dynamos are driven, so that one or other of the engines may be used at pleasure. These engines are each 12 horse-power, and are provided with a pair of heavy flywheels to ensure steadiness of motion. The lamps burn remarkably steady, there being no pulsation whatever visible in the light. The installation is worked on an average eight hours every night throughout the year, except Saturday, and not one working night has been missed since the commencement. The principal portion of the building lighted electrically is the composing room, in which there are about 120 lamps. This apartment, which measures some 60ft. by 40ft. by 70ft. in height, was formerly lit by the same number of gas jets. The temperature frequently ran as high as 85 degrees in winter and 95 degrees in summer. Since the introduction of the electric light the air is pure and wholesome, the thermometer rarely marking higher than 70 degrees during the night. Now, as to the cost of working this installation, which is really the all-important consideration. It must be understood that gas is not wholly superseded; it is partly used in the editorial department, and also in the offices before the electric light machinery is set in motion, as it is not considered economical to start the dynamos until a certain number of the compositors have commenced work. The usual time of starting is about 7 p.m., and the machinery is kept running during the night until three and sometimes four o'clock in the morning, with a pause of half an hour at supper time. In summer, however, the light is run continuously during the night, it being desirable to keep the temperature as cool as possible. During the twelve months' working a saving of about £120 was effected in the gas account, and this saving covered the interest on the cost of the electrical plant, the breakage of lamps, the wear and tear on the machinery, and the attendant's proportion of wages. The dynamo machinery performed 2,200 hours' work during the year, absorbing 19 indicated horse-power. This power was obtained at an expenditure of 418 cubic feet of gas per hour (*i.e.*, 22 cubic feet per horse-power per hour). The dynamo machines gave no trouble during the year, and needed no repairs; and they are now, after sixteen months' work, in good condition. Considering that the installation was worked for 2,200 hours, it is satisfactory that only 56 lamps were destroyed; of these about 15 were broken through carelessness or by accident, so that only 41 gave way owing to rupture or burning out of the carbon filaments. This, it must be admitted, is a very moderate loss in lamps. The average life of a lamp burning at its normal candle-power is usually estimated at 1,000 hours; but here we have several lamps running considerably longer than 2,000 hours. The long life of the lamp in the present case may be accounted for in two ways—1st, they are not incandesced to their normal power (being 20-candle lamps and run only at 17 candles); and, 2ndly, they are worked by alternate-current dynamo machinery. It is remarkable to note how considerably the life of a lamp is affected by a difference in the E.M.F. under which it is worked. Taking the actual work done in the installation under notice, and assuming that the average number of lamps run for the 2,200 hours was 130, we find the total cost of working is £278. 2s. 6d. This represents a fraction less than a farthing per lamp per hour—just about the same price as an ordinary gas jet burning five cubic feet per hour. From this it follows that the electric light, when used on a moderately large scale, can be maintained, lamp for lamp, at the same cost as gas."

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(Continued from page 511, Vol. XIV.)

These formulæ enable a comparison to be made of the squares of the currents, as indicated by a dynamometer, at different points of a line. The dynamometer readings will be as before $\frac{(\text{maximum I})^2}{2}$, that is to say,

$$\epsilon^2 \frac{C\pi}{2T\rho} \cdot e^{-2ax} \left\{ 1 + e^{-4a(l-x)} + 2 \cdot e^{-2a(l-x)} \cos 2a\overline{l-x} \right\}$$

This, when $x = 0$, is equal to

$$\epsilon^2 \frac{C\pi}{2T\rho} \cdot \left(1 + e^{-4al} + 2 \cdot e^{-2al} \cos 2al \right)$$

and, when $x = l$, it has for value

$$\epsilon^2 \frac{C\pi}{2T\rho} \cdot e^{-2al} 4.$$

The relation of the former to the latter is therefore

$$\frac{1 + e^{-4al} + 2e^{-2al} \cos 2al}{4e^{-2al}}$$

$$= \tfrac{1}{4} \left\{ e^{2al} + e^{-2al} + 2 \cos 2al \right\} \quad . \quad . \quad . \quad (\epsilon)$$

Which is equal to the series

$$1 + \frac{(2al)^4}{\underline{|4}} + \frac{(2al)^8}{\underline{|8}} + \ldots$$

and, therefore, always more than unity, however small l may be. Hence the dynamometer reading is a minimum at $x = l$.

This case corresponds to that of an alternating current machine in connection with a uniform cable possessing capacity. The point $x = l$ corresponds to a point of the cable half way between the terminals of the machine, at which point the potential is zero always, and ϵ corresponds to half the E.M.F. of the machine.

The comparative reading of the dynamometer at any point distant l from the central point in either direction will be

$$1 + \frac{(2al)^4}{\underline{|4}} + \frac{(2al)^8}{\underline{|8}} + \&c.$$

It is clear, therefore, that three readings of the dynamometer at points at measured distances apart from one another will suffice to determine the value of a, and $a = \sqrt{\rho \frac{C\pi}{2T}}$; therefore, if ρ, the rate of resistance, and 2 T, the periodic time, are known; C, the capacity of a unit of length of the conductor, can be accurately determined.

If we employ the symbols of hyperbolic trigonometry the expression (ϵ) may be written

$$\frac{\cosh 2al + \cos 2al}{2},$$

that is to say, the relation between the dynamometer readings at any point distant l from the central point or point of no potential, and at that central point is expressed by the mean of the hyperbolic and circular cosines, a result given before the Society of Telegraph-Engineers and Electricians by the author.

If there had been an ordinary conductor possessing no electrical capacity, but of such a resistance, B, that an alternating E.M.F. corresponding to the potential existing in the condenser cable at a point, viz. :—

$$\epsilon \cdot e^{-ax} \left\{ 1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a(l-x) \right\}^{\frac{1}{2}}$$

would produce the same effect on the dynamometer as is observed, then

$$\frac{\epsilon^2 e^{-2ax} \left\{ 1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a\overline{l-x} \right\}}{2B^2}$$

$$= \frac{\epsilon^2 C\pi}{2T\rho} e^{-2ax} \left\{ 1 + e^{-4a(l-x)} + 2e^{-2a(l-x)} \cos 2a\overline{l-x} \right\}$$

We deduce

$$B^2 = \frac{T\rho}{C\pi} \left\{ \frac{1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a(l-x)}{1 + e^{-4a(l-x)} + 2e^{-2a(l-x)} \cos 2a\overline{l-x}} \right\}$$

When $x = 0$,

$$B = \sqrt{\frac{T\rho}{C\pi}} \cdot \left\{ \frac{1 + e^{-4al} - 2e^{-2al} \cos 2al}{1 + e^{-4al} + 2e^{-2al} \cos 2al} \right\}^{\frac{1}{2}}$$

If $2al = \theta$, for brevity

$$B = \sqrt{\frac{T\rho}{C\pi}} \cdot \left\{ \frac{\frac{\theta^2}{\underline{|2}} + \frac{\theta^6}{\underline{|6}} + \frac{\theta^{10}}{\underline{|10}} + \ldots}{1 + \frac{\theta^4}{\underline{|4}} + \frac{\theta^8}{\underline{|8}} + \ldots} \right\}^{\frac{1}{2}}$$

When $\theta = 0$ the term in the bracket is equal to zero, when $\theta = \infty$ it is equal to unity.

Thus B increases from zero to $\sqrt{\frac{T\rho}{C\pi}}$, as l increases from zero to infinity.

Thus it will be seen how little the virtual resistance, as far as the dynamometer at the generating station is concerned, is increased by increasing the length of the cable. In fact, the virtual resistance tends to a limiting value $\sqrt{\frac{T\rho}{C\pi}}$.

The case of the open circuit differs from the last in that the source which produces the reflected current and potential is in the same phase as the primary source, so that the currents at the middle points neutralise each other. As in such a case no current passes across the middle point, the variation of the potentials along the line is entirely due to the propogation of electricity at the primary source ; the conductor may be cut at the middle point and the end treated as free and perfectly insulated, a point of no current, as in the former case it was a point of no variation in potential.

The *reflected* potential will be

$$\epsilon e^{-\sqrt{\frac{\rho C\pi}{2T}}(2l-x)} \sin \frac{\pi}{T} \left\{ t - \sqrt{\frac{\rho CT}{2\pi}} (2l-x) \right\},$$

and the reflected current, positive towards origin of x,

$$\epsilon \sqrt{\frac{C\pi}{T\rho}} e^{-\sqrt{\frac{\rho C\pi}{2T}}(2l-x)} \sin \frac{\pi}{T} \left\{ t - \sqrt{\frac{\rho CT}{2\pi}} (2l-x) + \frac{T}{4} \right\}$$

Combining the primary and secondary effects, and writing as before $\sqrt{\frac{\rho C\pi}{2T}} = a$, we have for potential at any time and place

$$E = \epsilon e^{-ax} \left\{ 1 + e^{-4a(l-x)} + 2e^{-2a(l-x)} \cos 2a(l-x) \right\}^{\frac{1}{2}} \sin \left(\frac{\pi t}{T} - ax - y \right),$$

where $$\tan y = \frac{e^{-2a(l-x)} \sin 2a(l-x)}{1 + e^{-2a(l-x)} \cos 2a(l-x)},$$

which shows that the phase of the potential is *postponed* by the *finite insulated* conductor, compared with the phase at the corresponding point of an *infinite* conductor.

The current at any place and point of time is given by

$$I = \epsilon \sqrt{\frac{C\pi}{T\rho}} e^{-ax} \left\{ 1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a(l-x) \right\}^{\frac{1}{2}} \sin \left(\frac{\pi t}{T} - ax + \frac{\pi}{4} + z \right),$$

where $$\tan z = \frac{e^{-2a(l-x)} \sin 2a(l-x)}{1 - e^{-2a(l-x)} \cos 2a(l-x)},$$

which shows that the phase of the current is *advanced* by the

Digitized by Google

finite insulated conductor, compared with the phase at the corresponding point of an infinite conductor. But in this case also the difference of the phases of E.M.F and current differs at different points of the circuit.

The dynamometer reading for any point will be

$$\epsilon^2 \frac{C\pi}{2T\rho} \cdot e^{-2ax} \left\{ 1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a(l-x) \right\}$$

If we write $\overline{l-x} = d$, and therefore $x = \overline{l-d}$, we have for the dynomometer readings at distance d from the free end

$$\epsilon^2 \frac{C\pi}{2T\rho} \cdot e^{-2a(l-d)} \left\{ 1 + e^{-4ad} - 2e^{-2ad} \cos 2ad \right\}$$

$$= \epsilon^2 \frac{C\pi}{2T\rho} e^{-2al} e^{2ad} \left\{ 1 + e^{-4ad} - 2e^{-2ad} \cos 2ad \right\}$$

$$= \epsilon^2 \frac{C\pi}{2T\rho} e^{-2al} \left\{ e^{2ad} + e^{-2ad} - 2\cos 2ad \right\}$$

Which may be written

$$\epsilon^2 \frac{C\pi}{2T\rho} e^{-2al} \left\{ \cosh 2ad - \cos 2ad \right\}$$

As in the former case, the virtnal resistance B may be found by dividing the maximum value of E by the maximum value of I; whence,

$$B = \sqrt{\frac{T\rho}{C\pi}} \left\{ \frac{1 + e^{-4a(l-x)} + 2e^{-2a(l-x)} \cos 2a(l-x)}{1 + e^{-4a(l-x)} - 2e^{-2a(l-x)} \cos 2a(l-x)} \right\}^{\frac{1}{2}}$$

In this expression put $x = 0$ and (for brevity) $2al = \theta$. Then B becomes

$$\sqrt{\frac{T\rho}{C\pi}} \left\{ \frac{1 + \frac{\theta^4}{\underline{|4}} + \frac{\theta^8}{\underline{|8}} + \ldots\ldots}{\frac{\theta^2}{\underline{|2}} + \frac{\theta^6}{\underline{|6}} + \frac{\theta^{10}}{\underline{|10}} + \ldots} \right\}^{\frac{1}{2}}$$

If $\theta = 0$, *i.e.*, when the length of the conductor l vanishes, the expression in the bracket is infinite. But if θ is infinite, *i.e.*, when the length of the conductor is infinite, the expression in the bracket becomes equal to unity. Thus B diminishes from infinity to $\sqrt{\frac{T\rho}{C\pi}}$ as increases from zero to infinity. Thus, in every case, $\sqrt{\frac{T\rho}{C\pi}}$ is the virtual resistance of an infinitely long cable, whether put to the earth or not.

The expressions for B may be made extremely simple by using the symbols of hyperbolic trigonometry. In the case of the conductor put to earth at distance l from the point of observation, we have

$$B_1 = \sqrt{\frac{T\rho}{C\pi}} \left\{ \frac{\cosh 2al - \cos 2al}{\cosh . 2al + \cos 2al} \right\}^{\frac{1}{2}}$$

and in the case of the conductor having a free end at distance l from the point of observation,

$$B_2 = \sqrt{\frac{T\rho}{C\pi}} \left\{ \frac{\cosh . 2al + \cos 2al}{\cosh . 2al - \cos 2al} \right\}^{\frac{1}{2}}$$

I propose to illustrate by numerical examples and tables the formulæ given in this article, already quite long enough. But the three cases considered have so close a connection with one another that it would have been undesirable to separate them by numerical matters; and the three can moreover be best treated simultaneously.

(To be continued.)

FIRING CARTRIDGES BY ELECTRICITY.—A design for the application of electricity for discharging firearms has just been patented by Mr. T. Page Wood, gunmaker, of Swindon and Bristol. The invention consists of an arrangement of wires through which the current of electricity is passed to the rear of the cartridge. The battery is carried in the butt of the weapon, and the act of pulling the trigger electrically connects the wires with the charge. In connection with this invention Mr. Wood has introduced a patent cartridge.

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(Continued from page 513, Vol. XIV)

The case of a Gramme ring last considered makes it necessary to distinguish between the useful and useless lines of force. In practice this is inconvenient, as we have no means to determine how many lines are useful and how many are useless. Even if we had an instrument by which we could determine the number of lines passing across the central space of the ring (the dotted lines in Fig. 14), it would hardly be possible to employ such an instrument on an actual machine, because the central space is almost entirely occupied by the spindle and hub or spokes which support the ring. It is therefore more convenient to disregard the useless lines altogether, and to introduce the conception of magnetic density for the purpose of estimating the number of useful lines passing actually along the core. According to this conception every square centimetre of core on the cross section C A carries a certain number, μ, of lines, and the total number of useful lines is found by multiplying this magnetic density μ with the area of cross section. It should be at once remarked that the magnetic density is not uniform throughout the area of the core, but is greatest near the outer periphery. For our purpose, however, we may take an average value for μ, and write

$$Z = 2\mu a b$$

where Z is the total number of useful lines, a the radial depth, and b the length of the core. This method of treating the question has also the further advantage of being equally applicable to drum armatures. We need only increase the radial depth a of the core until the central space has completely vanished to obtain a Gramme ring, which is magnetically and electrically equivalent to a Siemens armature of equal diameter. In this case all the internal wires of the Gramme winding would have to be crowded into the axis of the spindle, that is into a mathematical line. This, of course, is practically impossible, because the wires must have a certain thickness to carry the current, and must therefore occupy a certain space. But the argument still holds good; for whatever the space occupied by the bundle of wires, the current in one-half of the wires must always be in the opposite direction to that in the other half, and since the wires lie close together the effect of all these currents on the magnetic condition of the core is *nil*. Conversely the influence of the magnetism of the pole pieces on this bundle of wires must be *nil*, and the electromotive force of the armature is not increased by these wires. They serve merely as connecting links between the wires on the outer circumference, and if the connections could be made in any other way the armature would give the same electromotive force. This is actually done in the Siemens machine. The connection between the external wires is made across the ends of the drum, and thus the resistance of the armature is less than would be the case were the connection made by means of the internal bundle of wires. It is interesting to compare the Gramme and Siemens armatures with regard to resistance. The total amount of wire wound on a Siemens armature, whose length is b and diameter d, is theoretically

$$n(b + d),$$

though practically somewhat more, on account of the space occupied by the wires where they cross over on the ends. The length of each cross connection is therefore not equal to the straight diameter d, but to the meridian of the curved end surface. As a fair average we may take it that this surface is about midway between a hemisphere and a plane. The meridian of this surface would be about $\frac{d}{2}\left(\frac{\pi}{2} + 1\right)$, or nearly $1{\cdot}3\,d$. The actual length of wire on a Siemens armature having n turns is therefore

$$n(b + 1{\cdot}3\,d).$$

The actual length of wire on a Gramme armature is

$$2n(b + a).$$

The difference between the two is

$$\text{Gramme} - \text{Siemens} = n(b + 2a - 1{\cdot}3\,d).$$

Digitized by Google

If this difference be positive the Siemens method is more economical; if the difference be negative, the Gramme method requires less wire. The two are equally good if $b + 2a = 1{\cdot}3\,d$.

Before we can draw any conclusion from this formula, we must make an assumption regarding the proportion between depth of core and its diameter in the Gramme armature. In most modern machines this proportion lies between ·15 and ·20.

Taking ·175 as an average we find

$$b = {\cdot}95\,d$$

as the proportion between diameter and length of an armature at which the Siemens and Gramme methods give equal resistances.

If $b > {\cdot}95\,d$, the Siemens method will give less resistance; if $b < {\cdot}95$, the Gramme method will be preferable.

But to return to our problem of finding the electromotive force created in any of these armatures. If the central space in a Gramme ring be gradually diminished by increasing the radial depth of the core, we approach more and more a Siemens armature; and we reach it if $a = \frac{d}{2}$, the total number of useful lines being in this case

$$Z = \mu\,d\,b.$$

Substituting this value into our formula for $E\,a$, the electromotive force in the armature, we have for a Siemens machine,

$$E\,a = \mu\,d\,b\,N t\,n,$$

and for a Gramme machine,

$$E\,a = \mu\,2a\,b\,N t\,n.$$

It should be remarked that μ is not necessarily equal in both cases; generally speaking it is larger in the Gramme armature. The last formula is applicable to both cylindrical and disc armatures. The character of the armature is determined by the relative values of a and b. In the usual Gramme ring $a < b$, but in disc machines $a > b$. In the equation for $E\,a$, all the quantities are known, or can be obtained from measurements on the machine, except the coefficient μ, which is the number of lines of force passing through one square centimetre of core area at the diameter of commutation.

The aim in designing a dynamo should naturally be to obtain a maximum of electromotive force with a minimum expenditure of material, and at a reasonable speed. From this it follows that μ should be as large as possible. If we were to attempt to raise the E.M.F. by making a and b (the cross-section of the core) large, the whole machine would become too costly and bulky, whilst if we attempted to increase the E.M.F. by a greater number of turns (Nt) on the armature, the resistance of the latter would be too great for economical working. This expedient would also entail the further disadvantage of causing too much sparking at the brushes, as the reader can easily see by referring back to our mechanical model (Fig. 11), which illustrates the effect of self-induction. All these difficulties are overcome, or at least minimised, if the density of lines in the armature core is sufficiently great. In fact the value of μ is a measure for the excellence of the machine.

The above equations for $E\,a$ give the electromotive force in absolute measure. For practical purposes, it is more convenient to employ a formula which gives $E\,a$ directly in volts, and in which the coefficient μ is not a figure of thousands. In this modified form the equation is,

$$E\,a = \frac{\mu\,a\,b\,N t\,n}{1{,}000{,}000},$$

where $E\,a$ is the electromotive force in volts developed in the armature, a the radial depth of the core in inches, b its length in inches, Nt the number of turns of wire on the outer circumference of the armature counted all round, and n the number of revolutions per minute. The coefficient μ varies between 20 and 40 according to the design of the machine and the degree to which the field magnets are excited. Higher values for μ than 40 can be obtained, but at great expense of exciting power. As a fair average, we may take $\mu = 30$ if reckoned over the gross area of the core, including air spaces and insulation between the sub-divisions of the core. If the formula is to be applied to a Siemens or other machine having a drum armature, without any central space free of iron, then a is the radius of the core. The other symbols have the same signification as in the case of a Gramme armature.

In a given machine it is very easy to find μ experimentally. We would work the machine at its proper speed and note the current sent into the outer circuit, and the difference of potential between the two brushes. In the case of a shunt machine, or a compound machine, we would also measure the current used in the shunt coils, or we would calculate it from the electromotive force and the resistance of the shunt coils. Let Cs be the shunt current, c the external current, $E\,b$ the difference of potential at the brushes, and $R\,a$ the resistance of the armature, then the equation evidently obtains

$$E\,a = E\,b + R\,a(C + C\,s).$$

Having thus found $E\,a$, we can determine μ by the formula,

$$\mu = \frac{1{,}000{,}000\,E\,a}{a\,b\,N t\,n}.$$

So far, this is easy enough. But the difficulty is how to determine μ before the machine is actually made and tested—in other words, how to design the machine in order that the magnetic coefficient μ shall have a certain predetermined value.

To treat this question, we must refer back to our analogy between the magnetic and voltaic circuit. It was then pointed out (p. 346, Vol. XIV.) that according to this conception the number of lines produced by a certain exciting power in a wrought-iron electro-magnet is the ratio between that exciting power and the magnetic resistance in the circuit. It is customary to measure exciting power in ampere-turns; as regards magnetic resistance, however, no generally accepted unit does as yet exist. The number of lines created depends not only on the resistance of the circuit, but also on the material of that portion of the core which is directly under the influence of the coils. Remoter parts of the core seem to have only an influence as far as they affect the resistance. To make this clear by an example, imagine we have a horse-shoe magnet of the form shown in Fig. 15, where the length of the yoke is exactly equal to that of both cores.

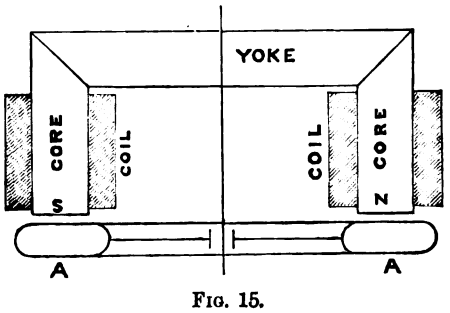

FIG. 15.

A magnet of such proportions could very well be employed in a disc machine, A A being the armature. As far as the magnetic resistance alone is concerned, it will be clearly all the same whether we make the cores of cast-iron and the yoke of wrought-iron, or *vice versâ*, for the lines would have in either case to traverse equal lengths of cast-iron and wrought-iron. Yet experience shows that it is preferable to make the cores of wrought-iron and the yoke of cast-iron. We are thus forced to the conclusion that the total number of lines is not simply ampere-turns divided by magnetic resistance, but that this proportion must be multiplied with some coefficient depending on the material of that part of the core which is immediately under the influence of the coils. What this coefficient is for different qualities of iron the author is unable to say, as he has not made sufficient experiments on this point. An investigation of this kind would be very instructive, and in the hope that some one of his readers might undertake it he would point out how the experiments should be made. Two magnets should be constructed, one with a cast-iron yoke and wrought-iron cores, the other with a wrought-iron yoke and cast-iron cores. In shape these magnets should be exactly alike, so that the same exciting coils can be used for either. To measure the number of lines created by various exciting currents in either

Digitized by Google

magnet, an armature, A A, in the shape of a flat Gramme ring should be used. The core of this armature would consist of the usual soft iron wire, but only one coil, or perhaps one turn of copper wire, should be wound round it. The terminals of this coil are to be connected to a delicate galvanometer, and the deflection must be noted whilst the armature is turned one-half revolution, so that the coil is moved from one neutral point to that on the opposite side. If certain precautions are taken, especially with regard to limiting the throw of the galvanometer, the latter is almost exactly proportional to the total number of lines cut by the coil in its transit from one side of the field to the other. In this way it would be possible to determine for different qualities of iron their relative value with regard to the creation of lines of force. The apparatus above described would also serve to show how many lines are created by a simple coil or solenoid without iron core, and how this number is multiplied by the presence of an iron core.

The author has made all his experiments on real dynamos, which could of course not be modified and arranged with the same facility as could a small model. Especially, the question of the relative value of cast iron and wrought iron could not be closely investigated, for it is too expensive to make different combinations of yokes and cores on a large scale. In one case he has, however, determined the difference between cast-iron and wrought-iron magnets. Both were adapted to receive the same armature (from one of the author's own dynamos designed to feed seventy 20-candle lamps), and he found that the cast-iron field gave 80 volts when at the same exciting power the wrought-iron field gave 100 volts. To obtain 100 volts with the cast-iron field the exciting power had to be more than doubled. The armature was a modified Gramme with a smooth core. Had it been provided with external iron projections like the Pacinotti, Bürgin, or Weston, the difference would probably not have been so great. The experiment proved conclusively that cast iron should not be employed for the cores of dynamo magnets, and in establishing our formula for the number of lines we will assume that the cores consist of soft wrought iron.

(To be continued.)

A CONTEMPORARY OF FRANKLIN.

Maximilian Hell, professor of astronomy and director of the Imperial Observatory of the University of Vienna, though better known perhaps for his astronomical researches, was an earnest student of electrical science. Born in 1720, at Chemnitz, in Hungary, where his father was director of the hydraulic machines belonging to the neighbouring mines, he would appear to have been destined for mechanical engineering both by parentage and opportunity. Accordingly we find his genius asserting itself in this direction during his early manhood. Having completed his school education at Neusol, he entered in 1738 into the society of the Jesuits, who in 1740 sent him to the college of Vienna. "At this seminary," we are told, "he studied philosophy for three years, during which time he displayed great mechanical genius, and employed his leisure hours in constructing water clocks, terrestrial and celestial globes, and machines of the like kind. In the years 1744 and 1745 he devoted himself to his favourite pursuit, mathematics, under the care of the celebrated Frœlich [a name not unknown in the electrical annals of the present day], and not only assisted Franz, the astronomer of the Jesuits' observatory, in his astronomical labours, but also in arranging the museum for experimental philosophy." Having gained distinction as a teacher of mathematics at various schools during the next three or four years, and obtained a reputation as a writer of mathematical works, we find him again at Neusol, in 1752; having been elevated to the rank of a priest in the previous year. About this period he began building the Observatory of Tyrnau, in conjunction with the director of the college of that town, Borgias Keri, the degree of doctor and the public professorship of mathematics at Clausenburg being conferred on him as a reward for his indefatigable zeal. He was also entrusted with the care of establishing a new college and an observatory at the latter place, and of providing the necessary philosophical and mathematical instruments, chemical apparatus, and books. Though his time was thus fully occupied he found leisure to study electrical phenomena, and is credited with important discoveries as to the effects of electricity, which corresponded with those of Franklin, Beccaria, and others. Those of our readers who have a good memory for historical facts will remember that it was about this time (1752) that Franklin made his celebrated kite experiments, and though news travelled slowly in those days, it is more than probable that Prof. Hell had heard of them. Unfortunately Hell's experiments were never published, though we are told that some account was given of them in Jaszlinsky's "Natural Philosophy," published at Tyrnau. Whilst at Clausenburg he again devoted himself to writing mathematical works intended more particularly for the use of his pupils, but was interrupted in his labours by being asked to accept the post of astronomer and director of the new observatory then being built at the Vienna University. This was in 1755. From this time until 1767 he appears to have devoted his energies to astronomical work, although the publication of a small work entitled, "An Introduction towards the Useful Employment of Artificial Magnets," shows that he still found time to continue his electrical studies. In the year 1767 Hell was invited by the then King of Denmark (Christian VII.) to observe the transit of Venus, which was predicted for the 3rd June, 1769, from an island in the arctic seas, near Wardoehuus, at the northern end of Europe. This invitation he accepted, setting out on the 28th April, 1768, and arriving at his destination on the 11th of October following. He built an observatory on the island, and in spite of many difficulties and dangers carried out a regular series of meteorological and magnetic observations from December, 1768, to June, 1769, in which latter month he set out on his return to Copenhagen. As the result of his plucky expedition, Hell promulgated a new theory of the aurora borealis, discovered that there was a great declination of the magnetic needle in different longitudes and latitudes, and that in lat. 70°, in which his observatory was situate, it varied continually. His observations were not confined to meteorological, geographical, or electrical matters, but were extended so as to embrace the history, religion, and language of the people amongst whom he had come, as well as the natural history of the district. The transit of Venus was very clearly observed, and the results of the whole expedition were remarkably good. These were communicated to the Academy of Sciences at Copenhagen on Hell's return, and were subsequently published. In 1770 he returned to Vienna, where he set about collecting and arranging the fruits of his journey with the intention of publishing them for the benefit of the scientific under the title of "Expeditio literaria ad Polum Arcticum." As ill fortune would have it, however, this work never appeared, and we are somewhat significantly told, remembering his connection with the Jesuits, "the cause of its suppression is not known." After this Hell appears to have busied himself with his astronomical records, which he kept regularly until his death in March, 1792. We hear no more of his electrical studies, though we are at liberty to conjecture that they were prosecuted with the characteristic vigour of the man. Some day, perhaps, they will be unearthed from the dust of forgetfulness and oblivion, and the electrical world may be astonished to find how much this Jesuit priest really knew about electricity.

THE SOUTH OF ENGLAND TELEPHONE COMPANY.—Notice is given that the first ordinary general meeting of this company will be held on Thursday next, at 1 p.m., at the Cannon-street Hotel, in conformity with the Companies' Acts, 1862-1880.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 15th inst. amounted to £2,734.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 15th May were £2,141, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th May are £3,811, as compared with £3,051 in the corresponding period of 1884. The January receipts, estimated at £5,447, realised £5,391.

NOTATION AND NOMENCLATURE.

The paper read and discussed at the last meeting of the Society of Telegraph Engineers will probably prove of some historic interest, inasmuch as it has compelled the Council to change their usual attitude of meditation for one of action. Some three or four years ago the suggestion was made to the Council of Telegraph Engineers that a committee should be formed for the purpose of considering the question of Electrical Notation and Nomenclature, but, as is usual in England when an initiative is to be taken, the suggestion was quietly shelved. From time to time since that period the question has been mooted in our columns and in the columns of our contemporary, the *Engineer*. M. Hospitalier, in France, and Messrs. Munro and Jamieson in England, working independently to provide pocket-books for electrical engineers, became tolerably familiar with the chaotic state of electrical notation and nomenclature. M. Hospitalier may claim priority in action, for the formation of the "Commission des Notation Electriques," by the International Society of Electricians, is due almost entirely to his energy and perseverance. This Commission has considered the question, and has drawn up an interim report, which at present is to a certain extent confidential; hence we can only refer to it in somewhat general terms. The question has, we are informed, been considered not only from the standpoint of the requirements of the electricians of France, but from the broader basis of cosmopolitan requirements.

At the meeting of the Telegraph Engineers last week we were told that the Council of that body had agreed to the formation of a committee to report upon the question, and to consult with the French Committee in order that the whole subject might be satisfactorily dealt with—once and for all. Unfortunately we cannot suppose that the French Committee will agree to discuss the question *de novo*; hence it remains simply for the new committee either to accept what has been done, with perhaps a little tinkering for form's sake, or to construct a system of its own. In the latter case we should have before us the rival systems of England and of France, and the universal system would be relegated to the distant future. We cannot help going out of the way to utter another protest at the general policy of the Society of Telegraph Engineers. The scientific position of England does not tolerate being constantly in the second or third rank; but this Society seems to rest satisfied with following and never leading. It should really represent the electrical voice of England, but it does nothing of the kind. In no one single thing does the Society take the rank it should take, and certainly would take if less timorous counsels prevailed. To return to our immedate subject, Mr. Jamieson's paper is admirable as showing how simple it is to pull anything to pieces; but when we consider it as a constructive system in contradistinction to a destructive criticism its value is not so great. The consideration of the question is not at all as simple as it looks. In the first place, it may be asked, are we to assume without discussion that the C.-G.-S. system is acceptable? Of course this is the French system, and it is partly accepted by English scientific writers, although some writers do not accept the system, but prefer the M.-G.-S. system. We have yet to learn, however, which of these systems really commends itself to practical men. Restricting the discussion more closely to the exigencies of electrical science, it will be seen that the existing chaos has grown out of the requirements of telegraphy, and this may form one of the strongest reasons why the developed system should be altogether out of place when used for the requirements of electrical engineering. It may not be to our taste—as pertaining more to the ranks of pure science than to those of applied science—to imagine that the men of theory must of necessity in many things give way to the men of practice; but it is a fact, nevertheless. On the face of it the supposition is only natural that the requirements of electric lighting, for example, are altogether apart from those of aerial or submarine telegraphy. The units used in telegraphy apply to quantities of a very minute nature as compared with those of electric lighting. The construction of dynamos will gradually go out of the hands of the electrician into those of the electro-mechanical engineer, who will suit his own taste and convenience as to the terms he uses; and unless a practical system in accordance with his views is adopted, he will create or import mechanical terms to satisfy his wants. The constructing engineer of the last new ironclad or Atlantic liner is not going to talk about the work developed in ergs, nor will the builders of dynamos in the near future be satisfied to follow the usage developed from telegraphic progress. We already find some makers designating their machines as of so many units, after the fashion of the Board of Trade. The units, however, adopted by the Board of Trade do not fare well in the hands of those who criticised Mr. Jamieson's paper, nor should we imagine that they would fare any better in the hands of a committee.

Should, however, the adoption of the C.-G.-S. system be confirmed, it will be difficult for any committee to differ materially from the conclusions arrived at by the French Committee. We should agree with Mr. Jamieson in using C as a symbol for "current," and not I as suggested by the French Committee; but instead of K for "capacity," we should

Digitized by Google

prefer to follow the system adopted in chemical notation and use the symbol Cp., leaving C.P. to indicate "candle-power." There is another practical consideration which has evidently escaped the attention of Mr. Jamieson when arranging his symbols, and this consideration also applies to the suggestions made by Mr. Munro. Those who are best acquainted with the troubles and trials of printing will understand that the multiplication of signs means not only the multiplication of expense in adding to the immense number of symbols already in use, but multiplies the probabilities of error. It is at the present time very difficult indeed, no matter how careful men may be, to get a mass of symbols, mathematical or otherwise, put into type without some very grave errors. The expense attached to this class of work is greatly in excess of that of ordinary printing, and therefore in the construction of any system of notation every effort should be made to introduce as few new symbols as possible, and those introduced should be of as simple a character as possible. It seems to us that the French Committee have not forgotten this point, and if we might venture the suggestion to the Society of Telegraph Engineers as to the formation of its committee, it would be that the names of several mechanical engineers and one or two practical printers be added to the committee, in order that questions which would not present themselves to an ordinary committee might be considered, and a more complete and practical system of notation and nomenclature devised.

CORRESPONDENCE.

ELECTRICAL CONDITION v. RECENT SCIENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There are one or two points in the letter from "S. E." in your last week's issue that I am afraid are not quite clear to me.

In the first place I should like to know how "S. E." measured the force necessary to extricate the needle of his electrometer after it had been jammed by the sudden rise of potential, and I don't see that, even if he measured that force accurately, he would be able to calculate from it the force necessary to jam the needle.

Would he also kindly explain the method he used for measuring the potential in the case of the gold leaves.—Yours, &c.,

S. E. R.

18th May, 1885.

P. S.—I enclose my card.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(Continued from page 13.)

21. To see if the actual behaviour of such cells at all bears out a hypothesis formed on the above plan, I have made some rough experiments on the lines suggested; that is, I passed the same current through different simple cells. There are so many sources of uncertainty and of variation that it would be very difficult to get really definite and reliable results. Thus, for instance, the back E.M.F. will depend considerably upon how long the current has been flowing, and so the readings will differ according to the time they are taken. The metals I used were zinc-zinc, zinc-copper, and zinc-platinum; and it was found necessary to put the cathode-plate in a porous cell to avoid deposition of zinc on it. But it was now difficult to compare the cells easily when arranged in series, because different porous pots had different resistances. I therefore ultimately decided to use the same porous pot and the same anode zinc plate, and to substitute the other plates one after the other, making the current as nearly the same each time as convenient (by adjusting resistance) and allowing for outstanding discrepancies. An amperemeter placed in circuit measured the current, and the voltameter used was a reflecting galvanometer with some 30,000 ohms in its circuit. Its indications were interpreted absolutely by tapping off, at the same time as the cells, the difference of potential between the terminals of an ohm (or $\frac{1}{4}$ or $\frac{1}{8}$ ohm) coil placed in the circuit.

Any two values of the strength of current enabled the internal resistance of the cell to be calculated, provided its E.M.F. remained constant. With low currents it did seem to be fairly constant, and a mean value of the internal resistance r is reckoned from these as $\frac{1}{2}$ ohm.

The area of each plate under the liquid was exactly the same, and measured 3in. by $2\frac{3}{4}$in. Both faces of each plate were exposed, though naturally one face was more active than the other.

The arithmetical reductions are rather long; the results are all that I give. It will be perceived they are anomalous in places, a great deal of this being dependent on whether the reading of E.M.F. was taken soon after a current-change or not. As I said before, the plan of experiment is avowedly rough, though the actual readings were carefully taken; but without understanding more about the circumstances of the case, and what possibilities of variation there are, I do not see how to plan a perfect system of experiment on the subject.

I will first give relative numbers, simply comparing the differences of potential between the terminals of the three cells when the same current is going through each, the resistance of each being the same, viz., $\frac{1}{2}$ ohm; and then I will interpret the observations absolutely, calculating the E.M.F. of the cell under different currents, and seeing what empirical formula will best fit it.

Relative Differences of Potential between the Terminals of three Voltameters of the same Resistance, through each of which the same current is driven by an auxiliary battery. Anode of each cell, zinc; cathode—zinc, copper, and platinum respectively.

In the above table the difference of potential between the terminals is written negative when it opposes the current, and positive when it helps it on.

We will now interpret similar measurements absolutely, reckoning the actual E.M.F. of each cell, and try to fit an empirical formula to it on the plan of those (in Sect. 20) already guessed; assuming $f(C)$ a linear function, for simplicity, until forced to try something more complex. It is quite impossible that $f(C)$ can be a linear function really, but it very likely begins by being so, and only for big currents diverges notably. A hyperbolic tangent function, at a guess, would seem most likely to represent the case properly.

Electromotive Force of a *Zinc-Zinc*, Dilute Sulphuric-Acid, Cell, of Resistance $\frac{1}{2}$ ohm, through which the specified currents are driven by two or three Grove's; each plate exposing 53 square centimetres on each face.

Current, in amperes, C.	Difference of potential between terminals, in volts.	Observed E.M.F. of cell (obtained by adding rC to the preceding column).	E.M.F. calculated from the formula $e = -\frac{1}{2}C$.

The agreement between the observed and calculated columns is not very bad; and the polarization E.M.F. does not show decided signs of breaking away from the law of simple proportion until a current-strength of 4 amperes is reached—say an intensity of ·04 ampere per square centimetre of total surface.

Here two alternative formulæ are given; it is a matter of opinion which shows the least divergencies from the column of observed values.

The first is the one most naturally suggested by the theoretical considerations of sect. 20, the ·8 standing for Zn/O − Cu/O, or what is commonly called Zn/Cu.

Electromotive Force of a *Zinc-Platinum* Dilute Sulphuric-Acid, Cell, of Resistance ½ ohm, through which the specified currents are driven by two or three Grove's; each plate exposing 53 square centimetres of surface on either side. E.M.F. reckoned positive when it helps the current on.

Current, in amperes, C.	Difference of potential between terminals, in volts.	Observed E.M.F. of cell (obtained by adding rC to the preceding column).	E.M.F. calculated from the empiriecal formula $e = \cdot4 - \cdot1$ C.	F.M.F. calculated from the formula $e = 1\cdot2 - \frac{1}{3}$ C.

Here also are two alternative formulæ given, of which the first agrees best with the experimental results. But it is very strange that the E.M.F. of this cell should be so low when the current is feeble: it is scarcely more than that of the copper cell. The only way I see of accounting for the error (if error it be) is that the platinum was put into the liquid after the copper plate, and it was sometimes found coated with a very thin evanescent film of copper when taken out. Theoretical considerations would suggest something more like the second formula as the probable E.M.F., the 1·2 being what is ordinarily called Zn/Pt.

22. I can now continue the quotation of the remainder of the preliminary notes with the certainty that they will be at any rate intelligible. I begin with statements intended to be true for substances of every kind, and then specialise them for the case of metals.

III. *Statements believed by the writer to be true, though not entirely orthodox.*

xii. A substance immersed in any medium tending to act upon it chemically is (unless it is actually attacked) at a different potential to the medium in contact with it; positive if the active element in the medium is electro-positive, negative if the active element is electro-negative.

xiii. The above difference of potential can be calculated approximately from the potential energy of combination between the substance and the medium; the energy being measured by compelling the combination to occur, and observing the heat produced per amount of substance corresponding to one unit of electricity.

xiv. In addition to this contact-force, due to potential chemical action or chemical strain, there is another which is independent of chemical properties but which seems to be greatest for badly conducting solids, and which is in every case superposed upon the former contact-force, the two being observed together and called the Volta effect. Very little is known about this latter force except in the case of metals; and in these it varies with temperature, and is small. In the case of non-metals it is often much larger than the chemical contact-force.*

xv. The total contact-force at any junction can be experimentally determined by measuring the reversible energy developed or absorbed there per unit quantity of electricity conveyed across the junction (practical difficulties, caused by irreversible disturbances, being supposed overcome).†

xvi. In a chain of any substances whatever, the resultant E.M.F. between any two points is equal to the sum of the true contact-forces acting across every section of the chain between the given points (neglecting magnetic or impressed forces).

xvii. In a closed chain the sum of the "Volta forces," measured electrostatically in any (the same) medium, is equal to the sum of the true contact-forces; whether each individual Volta force be equal to each individual true force or not. See section 7.

xviii. Wherever a current flows across a seat of E.M.F., there it must gain or lose energy at a rate numerically equal to the E.M.F. multiplied by the strength of the current.‡

Development of the above and special application to Metals.

xix. A metal is not at the potential of the air touching it, but is always slightly below that potential by an amount roughly proportional to its heat of combustion, and calculable, at any rate approximately, from it. For instance, clean zinc is probably about 1·8 volt below the air, copper about ·8 volt below, and so on. If an ordinary oxodising medium be substituted for "air" in the above statement it makes but little difference.

xx. Two metals put into contact reduce each other instantly to practically the same potential; and consequently the most oxidisable one receives from the other a positive charge, the effect of which can be observed electrostatically.

xxi. There is a slight true contact-force at the junction of two metals which prevents their reduction to *exactly* the same potential; but the outstanding difference is small, and varies with temperature. It can be measured thermoelectrically by the Peltier effect, but in no other known way. It is probably entirely independent of surrounding media, metallic or otherwise.§

xxii. If two metals are in contact, the potential of the medium surrounding them is no longer uniform; if a dielectric it is in a state of strain, if an electrolyte it conveys a current.

xxiii. In the former case the major part of the total difference of potential is related closely to the difference of the potential energies of combination, and is approximately calculable therefrom. In the latter case the total E.M.F. is calculable accurately from the energy of the chemical processes going on, minus or plus the energies concerned in reversible heat-effects.‖

xxiii *a*. "The E.M.F. of an electro-chemical apparatus" whose energy is entirely expended in maintaining a current "is equal to the mechanical equivalent of the chemical action on one electro-chemical equivalent of the substance." (Thomson.)

xxiii *b*. "If the action in a cell consists in part of irreversible processes, such as (1) frictional generation of heat, (2) diffusion of primary or secondary products, (3) any other action which is not reversed with the current, there will be a certain dissipation of energy, and the E.M.F. of the circuit will be less than the loss of intrinsic energy corresponding to the electrolysis of one electro-chemical equivalent. It is only the strictly reversible processes that must be taken into account in calculating the E.M.F. of circuit." (Maxwell: Elementary Electricity, p. 148.)

xxiv. There are two distinct and independent kinds of series in which metals (and possibly all solids) can be placed: one kind depends on the dielectric or electrolytic medium in which the bodies are immersed, the other kind depends on temperature. The one is the real Volta series, but it is the commonly observed Volta series minus the Peltier; the other is the Peltier or thermoelectric series. To reckon up the total E.M.F. of a circuit, we may take differences of numbers from each series and add them together.

---

* I here assume, what I suppose is recognised as true, that what is known as frictional generation of electricity is really due to a contact-force between the substances rubbed—a force which is exceedingly great for insulators (see § 19). Davy seems to have held this view, from a note on p. 50 of his Bakerian lecture in 1806, cited before.

† These difficulties are, however, tremendous for most substances except metals. M. Bouty's is the only attempt I know of to examine junction-energy between metals and solutions of their salts, which is the case next in simplicity to metals. Observe that the statement says *energy*, not heat only.

‡ A current gains energy at any junction at which heat is absorbed, or chemical combination permitted, or any other form of energy destroyed, by the passage of the current. The current gains the energy which has in the other form disappeared.

A current loses energy at a point where it causes other forms of energy to make their appearance; *e.g.* generation of heat, decomposition of chemical compounds, &c.

§ To distinguish between Peltier-force and Volta force henceforward it will be best to write Bi/Sb or Zn/Cu for the former, and Zn/Air/Cu or Fe/Water/Pt for the latter. The force electroscopically observed is Air/Zn/Cu/Air, but this involves both; the right way of denoting the Volta effect pure and simple is Zn/Air/Cu.

‖ Such, for instance, as we have been discussing under the head of inconstant or simple voltaic batteries (sects. 19-21). These reversible heat-effects indicate the presence if thermal contact-force, which, wherever they exist, prevent chemical data from giving E.M.F. accurately: they also must be taken into account. We have called them Joule or Bouty effects.

Digitized by Google

23. It is necessary to illustrate the meaning of this last statement, No. xxiv. By real "Volta series" I mean such series as we have attempted to calculate from purely chemical data, because they depend on chemical tendencies. By "Peltier or thermoelectric series" I mean those giving a purely physical E.M.F., produced we know not quite how, whose energy-source is not chemical but thermal. We have on the one hand a number of Volta series, each for a special medium, and on the other a table of thermoelectric powers at different temperatures. The latter can be conveniently represented by a number of curves, because temperature varies continuously; Volta series, on the other hand, can hardly be represented geometrically, because the transition from one medium to another is probably *per saltum*; at least, it is not known what is the effect of mixing media, and so passing gradually from one to the next.

We have given several Volta series; and, for the sake of completeness, I will now give some Peltier series for a few substances according to the experiments of Professor Tait at different Centigrade temperatures. Expressing each number as a function of the temperature, we are able to give an infinite number of Peltier series in one table. The range of temperature over which this table may be interpreted is from $-18°$ to $400°$ or so, provided the metals do nor begin to melt. Non-metallic substances have not yet been introduced into such series: much experimental work remains to be done before they can be. The metals used by Tait were not chemically pure.

True Contact E.M.F. or Peltier Series. (Microvolts.)

Metals.	At any Temperature $t°$ C.	At 10° C.	At 100° C.
Iron	$-4760-3{\cdot}94t+{\cdot}0487t^2$	−4795	−4667
Hard Platinum	$-718-{\cdot}54t+{\cdot}0075t^2$	− 722	− 697
Soft Platinum	$+168+3{\cdot}63t+{\cdot}011t^2$	+ 205	+ 641
Magnesium	$-618+{\cdot}36t+{\cdot}0095t^2$	− 613	− 487
German Silver	$+3310+26{\cdot}17t+{\cdot}0512t^2$	+3577	+6439
Cadmium	$-731-14{\cdot}46t-{\cdot}0429t^2$	− 880	−2606
Zinc	$-643+8{\cdot}95t-{\cdot}024t^2$	− 735	−1778
Silver	$-590-6{\cdot}26t-{\cdot}015t^2$	− 654	−1366
Lead	0	0	0
Copper	$-374-3{\cdot}96t-{\cdot}0095t^2$	− 415	− 865
Tin	$+118-1{\cdot}08t-{\cdot}0055t^2$	+ 107	− 45
Aluminium	$+211-{\cdot}31t-{\cdot}0039t^2$	+ 207	+ 141
Palladium	$+1718+16{\cdot}15t+{\cdot}036t^2$	+1883	+3693
Hypothetical* Mercury (Gaugain)	$+1800+4{\cdot}6t-{\cdot}007t^2$	+1845	+2190

* This row of numbers is little better than a guess from some curves given in Wiedemann's *Elektricität*. A more probable deduction from some quite new experiments of C. L. Weber (Wied. *Ann.* November, 1884), gives, for mercury, $1181+5{\cdot}68t+{\cdot}005t^2$. (*Cf.* note to sect. 27.)

To find the E.M.F. of a junction at a specified temperature we have only to subtract the numbers in the above table, inserting the value of the temperature. Thus a junction of zinc and copper at 10° has an E.M.F. of 320 microvolts, acting from copper to zinc; and a unit current sent across such a junction from copper to zinc, or from zinc to copper, absorbs or generates heat at the rate of 320 microwatts, and the current gains or loses energy at the same rate. Clerk-Maxwell says that the force is one microvolt, and that it acts from zinc to copper ('Elementary Electricity,' p. 149, *note*); but he only means, I suppose, that the E.M.F. of a zinc-copper *circuit* with one junction a degree hotter than the other is a microvolt, and is such as to drive the current from zinc to copper across the cooler junction; at least this is true above $-60°$ or $-80°$.*

Hitherto we have supposed the circuit to be all at one temperature; but if different parts are at different temperatures we shall have to use a yet further series, viz., a Thomson series, for the E.M.F. acting in any one substance with a difference of temperature between its ends, or the force acting at a junction of two pieces of the same metal at different temperatures. This series can be deduced from the preceding, using only the coefficient of t^2, and multiplying it by the difference of the squares of the *absolute* temperatures of the two ends of the piece of metal. Such a series then stands thus:—

Thomson Series, or E.M.F. in a metal whose ends differ in temperature. (Microvolts.)

Iron	$\cdot0487\,(t_1-t_2)\left\{274+\frac{1}{2}(t_1+t_2)\right\}$
German silver	$\cdot0512\,(t_1-t_2)\left\{274+\frac{1}{2}(t_1+t_2)\right\}$
Zinc	$-\cdot024\,(t_1-t_2)\left\{274+\frac{1}{2}(t_1+t_2)\right\}$

and so on.

Whether a series of this sort can be made to include any non-metallic conductors also has not yet been discovered. M. Bouty's experiments provisionally indicate the very interesting fact that Sir W. Thomson's general thermodynamic laws of the thermoelectric circuit apply perfectly to circuits which include some electrolytes as well as metals.

Now the meaning of statement No. xxiv. is as follows: Regard zinc and copper in contact as a circuit completed by air or by water as the case may be, and let the temperature be uniform, and say 10°; to reckon up the total E.M.F. we must look in the proper Volta series for Zn/air (or Zn/water), which we find 1·8 say; for Zn/Cu, which we don't find, or find zero; for Cu/air, which we find ·8. Then we must look in the 10° Peltier series for Zn/air or Zn/water, which at present we shall not find there for want of data (possibly we have no right to put them there if we had data); for Zn/Cu, which we find about 320 microvolts; and for Cu/air, which again we don't find. Add them all up with their proper signs, and we have the total E.M.F. of the circuit.

Again, consider the case of a Daniell cell at a given temperature producing a current; we shall have to look in each series for $Zn/ZnSO_4$, for $ZnSO_4/CuSO_4$, for $CuSO_4/Cu$, and for Cu/Zn, and add them all up. It is true that these tables of numbers have practically yet to be made, for at present they include so few substances; but that does not affect the question of the existence and independence of these two kinds of series.

It is, of course, a question how far *all* E.M.F. of contact may be found to depend on chemical tendency. For instance, when bismuth and antimony are put into contact, does the E.M.F. developed measure the alloying affinity of these two metals? When sodium is dropped into mercury, does the heat produced represent the thermoelectric power of a sodium-mercury junction? When metal touches glass, does the tremendous E.M.F. developed represent a tendency of the metal to combine with the glass? These are questions for experiment to decide; but to me it does not seem probable that it will reply in the affirmative.

We know that Sir W. Thomson, and Davy before him, considered the apparent contact-force at the junction of zinc and copper to be due to the chemical affinity between these two metals, and to be measured by the heat of formation of brass; but this we have seen strong reasons for disbelieving. It sounds more probable that the real contact-force at a junction of bismuth and antimony should be due to the chemical affinity between these metals; but perhaps it is no more true. The greater part of a contact-force of this kind is probably due to a physical difference between the metals, such as difference in atomic velocity, and has no close relation to their chemical affinities for each other. It is, however, just possible that *part* of a metallic junction-force is due to chemical tendency between the two metals in contact. For instance, take the case of zinc and copper. There is, I suppose, an undoubted affinity between them, as shown by the formation of brass under proper conditions. [If chemists assume the right to demur to this, on the ground that the two metals mix equally well in any proportions, one can choose any other pair of metals—say, perhaps, copper and tin—for which the statement does not hold.] Now does this affinity result in any E.M.F. between them on making contact? This question, I apprehend, is to be answered by passing a current for a long time across a copper-zinc junction and seeing if any brass does, after a long time, result. Thermopiles show a curious secular deterioration with use, and it may be that some alloying action goes on, though I have never heard of its being noticed. But if no such alloying goes on during the passage of a current, then I should say that, in whatever ways chemical affinity between two metals is able to show itself, it does not show itself as an E.M.F.

Observe, I do not for a moment question the existence of a few hundred microvolts of E.M.F. at a zinc-copper junction. I only ask, is this chemical, or is it physical, or is it a mixture of the two? Statement No. xxiv. is general enough to take into account the possibility of its being a mixture of the two at every kind of junction. It is easy to write one of them zero, if so it turns out.

24. We have been led into a pretty wide discussion of contact-force in general; and, before digressing again on the question of a contact-force-determination of the size of atoms, it may be convenient here to quote the remainder of my preliminary notes, which aim at summarising, in a compact form, the main argument with respect to the immediate subject of discussion, viz., the seat of electromotive force in a voltaic cell, and in ordinary Volta-condenser experiments.

IV. *Brief Summary of the Argument.*

xxv. Wherever a current gains or loses energy, *there* must be a seat of E.M.F; and conversely, wherever there is a seat of E.M.F. a current must lose or gain energy in passing it.*

xxvi. A current gains no appreciable energy in crossing from copper to zinc, hence there is no appreciable E.M.F. there.

xxvii. When a current flows from zinc to acid, the energy of the combination which occurs is by no means accounted for by the heat there

* It is always easy to tell from thermoelectric data which way the force acts at a junction; but it is not always the same way as the current flows, by any means. A current, excited by differences of temperature in a simple metallic circuit, may be urged against the force at *both* junctions. This is the case, for instance, in a copper-iron circuit with one junction above 275° and the other below it by a greater amount. It is customary to say that the current flows across a hot junction from the metal of higher to the metal of lower thermoelectric value; this is not necessarily true. The safe statement is to say that the electromotive force acts from high to low thermoelectric value, at either junction.

* *Note added January* 1885.—My attention has just been called to an article by Mr. Oliver Heaviside in the 'Electrician' of 2nd February, 1884, in which he states views very like those contained in these statements. Had I known of this paper earlier I should of course have mentioned it, but I did not know of it.

Mr. Sprague also, in his book on 'Electricity, its Theory, Sources, and Applications,' on page 331 expresses his belief in much the same sort of way. Although Mr. Sprague is rather too much occupied in tilting against what he considers the absurdities of orthodox and "mathematical" views to work out his own ideas in a very thorough and clear form, there can be no doubt that he has in his own way arrived at very many of the same conclusions as Clerk-Maxwell, though of course in a far less profound and satisfactory manner. He has scarcely received the credit due to him for this, and a cutting review of his book in 'Nature' some years back, though justified in parts by Mr. Sprague's supercilious tone, yet falls into more important errors regarding electrical *facts* than Mr. Sprague himself falls into. See 'Nature,' June 24, 1875, vol. xii. p. 144.

Digitized by Google

generated, and the balance is gained by the current ; hence at a zinc-acid junction there must be a considerable E.M.F. (say at a maximum 2·3 volts).

xxviii. A piece of zinc immersed in acid is therefore at a lower potential than the acid, though how much lower it is impossible precisely to say, because no actual chemical action occurs. [If chemical action does occur, it is due to impurities, or at any rate to local currents, and is of the nature of a disturbance.]

xxix. A piece of zinc, half in air and half in water, causes no great difference of potential between the air and the water (Thomson, Clifton, Ayrton and Perry, &c.) ; consequently air must behave much like water.

xxx. If it makes the air slightly positive to the water, as it does (Hankel), it may mean that the potential-energy of combination of air with zinc is slightly greater than that of water, or it may represent a difference in the thermoelectric contact-forces between zinc and air and zinc and water, or it may depend on a contact-force between air and water. [If such a contact-force between air and water exists, it is obviously of great importance in the theory of atmospheric electricity, for the slow sinking of mist-globules through the air would render them electrical.]*

xxxi. Condenser methods of investigating contact-force no more avoid the necessity for unknown contacts than do straightforward electrometer or galvanometer methods ; the circuit is completed by air in the one case and by metal in the other, and the E.M.F. of an air-contact is more hopelessly unknown than that of a metal-contact.

xxxii. All electrostatic determinations of contact-force are really determinations of the sum of at least three such forces, none of which are knowable separately by this means.

xxxiii. The only direct way of investigating contact-force is by the Peltier effect or its analogues. [Maxwell.]

xxxiv. Zinc and copper in contact are oppositely charged, but are not at very different potentials ; they were at different potentials before contact, but the contact has nearly equalised them.

xxxv. The potential of the medium surrounding them is, however, not uniform. If a dielectric, it is in a state of strain ; if an electrolyte, it is conveying a current.

(To be continued.)

ELECTRICAL DEFINITIONS, NOMENCLATURE, AND NOTATION.†

With the rapid progress that has lately been made in electrical science and its applications, there has sprung up a new and fast-increasing class of practical electricians. These, partly from necessity, and partly from well-meant respect, have adopted and applied the old terms and expressions which appeared suitable to their predecessors, as well as coined not a few new ones ; until now their vocabulary is in considerable confusion, and, as all must admit, requires sifting and reform.

Nothing is more tantalising and perplexing than the different modes of expression and symbols used by different authors, and sometimes by the same author, to explain and interpret one and the same thing or result. All this might be avoided if an international system of definitions, nomenclature, and notation was agreed upon and legalised. The rapidity with which the new definitions of the ohm, ampere, and volt (issued and legalised last spring at Paris by the International Congress of Electricians) were universally adopted shows this. These definitions should be still further extended to other electrical units. They should embrace a suitable system of notation, whereby electricians could represent in symbols and letters, terms, expressions, and formulæ of common occurrence, in a similar manner to that adopted by chemists in connection with chemical elements and their combinations. Last session the author promised a communication to the Society on this subject, and, being again reminded by the Secretary of his unfulfilled promise, he now submits a few of the more apparent instances where ambiguity or want of uniformity exists, with suggestions, in the hope that a discussion may follow, and that a Committee of this Society may be formed to consider and draw up a series of definitions, nomenclature, and notation that would be generally acceptable. The proposed Committee might then confer with the French Committee, also with a similar Committee appointed by the British Association, and finally this important question should be referred to the International Congress of Electricians, in order that they may legalise and issue their decisions in a similar manner to that adopted by them in the case of the ohm, the ampere, and the volt. Undoubtedly, if such a course were adopted, most beneficial results would accrue to all concerned.

Only last November, M. Hospitalier brought this subject prominently before the International Society of Electricians at Paris, and strongly advocated an investigation, so that you will no doubt have their support and concurrence.‡

"Sur la proposition du Président, l'assemblée décide qu'une Commission spéciale sera nommée à l'effet de rechercher les meilleures méthodes à adopter pour les notations électriques et de codifier ces notations.

"M. le Président propose, au nom du Bureau, d'appeler à faire partie de la Commission des notations électriques.

"MM. Ed. Becquerel.	MM. H. Becquerel.

"L'assemblée adopte cette liste à l'unanimité."

Examples.—1. At the very outset students are perplexed by such different terms as "Ordinary* or Static or Frictional or High-tension Electricity." One author will tell his readers or students : "For a long time the name Frictional Electricity was given to a group of phenomena produced by electrical charges. This is an improper expression, because friction is only one means for producing electrical charges."† Another says : "Static Electricity is, however, a misnomer ; it has no existence ; all the phenomena are due to static strains, but there is always a gradual loss called leakage, which is, however, the current due to the actual conductivity of all circuits, and every motion set up by so-called static electricity implies a transfer of energy and action occurring in a field of force set up in the form of strains in the particular inductive circuit in which the motions occur."‡ A third objects to the word "tension" in respect to electricity, and points out that "all the phenomena observable in connection with so-called High-tension Electricity may be produced by electricity drawn from batteries or dynamos if the electromotive force or difference of potential is sufficiently increased." Would not the term "Electro-statics" be more suitable and comprehensive?§

2. The old nomenclature "vitreous" and "resinous," as applied to substances which when rubbed by certain other substances produce opposite electrical properties, and the scholastic one and two fluid theories based upon these effects, should be discarded for the more comprehensive modern theory of electric polarity of molecules or continuous particles, expressed by "positive" and "negative," or by the algebraical signs (+) and (−).

3. "Electrics," "dielectrics," "non-conductors," "insulators," and "isolators" are terms used by different writers to express a condition or behaviour of certain materials with respect to electricity, in contradistinction to the terms "non-electrics" or "conductors," as applied to other materials. The words "electrics," "non-conductors," and "non-electrics" are, strictly speaking, meaningless, because all materials may be termed electrics and all conductors, only differing in degree. The words "isolators" and "isolation" (from the French verb *isoler*, to isolate or separate) should give way to "insulators" and "insulation" as applied to substances which offer a comparatively greater resistance to electricity than semi or good conductors used in connection with the apparatus being referred to at the time.

The term "dielectric"‖ was first used by Faraday on finding that conduction was effected by induction (of polarity from molecule to molecule), and is generally employed by practical electricians when speaking of the inductive capacity of the insulating material surrounding the conductor of leading wires or submarine cables, or that placed between the plates of a condenser. In this sense, viz., of a body transmitting electric induction, or capable of undergoing electric stress, and retaining the stressed condition, it is a very appropriate term to use.

4. The term "accumulator" is the name given in several text-books to apparatus, such as the Leyden jar or condenser, for receiving and retaining quantities of electricity, but has been lately inappropriately applied to secondary batteries, which do not accumulate electricity.

5. "Cascade," as applied to Leyden jars, should give way to "series."

6. "Tension,"¶ "potential," and electromotive force," are terms which, when variously and indiscriminately applied, have given rise to considerable confusion and a great deal of writing in trying to define them. If we consider "tension" as simply the stress put upon the circuit by the electromotive force, and not in the sense that it used to be employed (for example : "Join up a battery or set of condensers for tension"), it might do very well if kept in its place ; but it can easily be dispensed with. "Potential" is a word that has also given great trouble. We find in "Sprague's Electricity"** no less than three pages devoted to an explanation of the different ways in which the words "tension" and "potential" are employed. Clerk Maxwell said : "The theory of electro-statics is greatly simplified by the introduction of this new conception of potential." "As soon as we pass from electrostatics to other deparments of electrical science, we find that the conception of potential is no longer available, except when used in a restricted sense and under carefully-defined conditions." "In other parts of electrical science we have to deal with electromotive force in cases where 'potential' and consequential 'potential difference' are words without meaning." Professor Fleeming Jenkin, in his well-known text-book on electricity and

§ Electricity and Magnetism," by Clerk Maxwell, Vol. I., Part 1.

‖ Faraday's "Experimental Researches," p. 364. "I use the word *dielectric* to express that substance through or across which the electric forces are acting." (See also pp. 537, 538.)

¶ For a good definition of these terms, see "Electricity and Magnetism," by Clerk Maxwell, vol. i., p. 49.

** 1884 edition, pp. 58—62.

Digitized by Google

magnetism, devotes twenty-six pages to "potential," and defines "unit difference of potential or electromotive force in electrostatic measure to exist between two points when the unit quantity of electricity in passing from one to the other will do the unit amount of work." "The property of producing a difference of potential may be said to be due to a peculiar force, to which force the name *electromotive force* is given." "The words *electromotive force* and *difference of potential* are used frequently one for the other, but they are not, strictly speaking, identical." "Electromotive force is the more general term of the two, and includes difference of potential as one of its forms." "Potential" might well be reserved for electrostatics, and "electromotive force" for electro-kinematics, or current electricity, and thus prevent confusion. The word "electric-pressure" has come into vogue lately, and strongly appeals to those of a mechanical turn of mind, seeing that the hydraulic simile of "head" or "pressure" is often brought forward to assist in explaining the terms "potential" and "electromotive force."

7. In magnetism we find the same want of uniformity exists. Take the case of a freely-suspended magnetised needle. The pole which turns towards the geographical north is variously called the "austral pole," "north pole," "north-seeking pole," "marked pole," and is painted red by Sir Wm. Thomson, while Sir Wm. George Airy, Professor Guthrie, and others paint it blue. It is sometimes indicated by French makers by the letter A, and by British by the letter N. The pole which turns towards the geographical south is correspondingly called the "boreal pole," "south pole," "south-seeking pole," "non-marked pole," painted blue by Thomson, and red by Airy, Guthrie, and others, and indicated by the letters B or S. Such is the general doubt and diversity in regard to the nomenclature on this subject, that each author on magnetism considers it necessary to state at the outset which term and symbol he intends to apply. If once for all the pole which turns towards the north was termed the "*north* pole," painted red, and indicated by the letter N, and the opposite pole was termed the "*south* pole," painted blue, and indicated by the letter S, much vexation would be saved. The French terms "austral" and "boreal," with letters A and B, should be obliterated. In this way the earth would have a uniformly recognised polarity, which would of course be opposite to that of the magnetised needle—in other words, the true north pole of the earth would be that situated near the geographical south pole.*

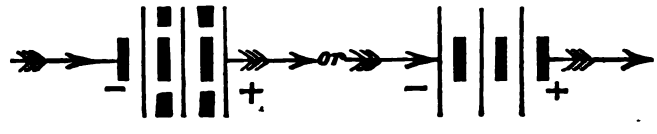
8. Sailors and some writers on the mariner's compass call the angle which the magnetic meridian makes with the geographical meridian the "variation" of the compass, while electricians call it the "declination." Variation is, properly speaking, the hourly, diurnal, annual, or secular changes which occur in the value of the elements of terrestrial magnetism. This leads to great confusion and argument between the electricians and the officers of a telegraph steamer. The declination for each place is marked on the Admiralty charts. Sailors also speak of the "deviation" of a compass, meaning by that the local error due to the resultant of the quadrantal, semicircular, and heeling errors. It would be far better if they simply spoke of the "compass error," or angle which the meridian of their compass-needle makes with the true north and south magnetic bearings. This deviatian or compass error arises from local magnetic influences on board ship. Sir William Thomson's well-known compass, when properly adjusted on board a ship, has no compass error, and therefore the only thing to guard against and correct for in the steering of a ship is the declination of the place where the ship may be at the time of observation. Of course, if the magnetism of the ship changes in the slightest, due to a change of cargo or position thereof (if of iron or steel), or due to buffeting the waves for some time on one course, a slight error will creep in, but the compass can be soon adjusted to the new condition of affairs, and the officers have therefore seldom to think of or even speak of "deviation" or compass "error."

9. When we come to electricity generated by batteries, we find the expressions "galvanism," "voltaic electricity," "dynamic electricity," "electro-kinetics," "current electricity,"† &c., according to the fancy of the writer or speaker. Surely one name might suffice; and certainly the older terms "galvanism" and "voltaic electricity" might well be left to the past. The simple term "current electricity" seems to commend itself, as most of the effects in connection with this branch of the subject have reference to electricity as if it was in motion or distributing itself over a conductor.

10. "Density of current" and "intensity of current" often cause great confusion. "Density of current" should only be used in the case of electrolysis or electro-deposition of metals. Here it means the amperes per unit of surface of the cathode. In electro-statics "surface density" or "electric density" means the quantity per unit area of surface. "Intensity" was used at one time in the same sense as "electromotive force" is now, and therefore not so much out of place there; but several writers, notably Prof. Silvanus Thompson, have thought fit to borrow the French term "*intensité de courant*" wholesale, instead of a translation thereof, and symbolise it by the letter I. The literal translation of the French word *intensité* being strength or amount, therefore the expression "current strength," or simply "current," symbolised by C, is far preferable, for it conveys the correct meaning of the quantity in a given time. With a little pressure, French electricians would no doubt agree to the symbol C instead of I, to promote uniformity. Then I might be reserved for intensity of magnetism, where it suits very well.

11. "Positive electrode," "(+) terminal," "zincode," "anode," "positive pole," and "negative plate," severally used by different writers to designate that end of a cell, battery, or pile where the current leaves, and "negative electrode," "(−) terminal," "platinode," "kathode" or "cathode," "negative pole," "chlorous pole," "positive plate," where the current returns to or enters the same, requires revising and simplifying, more especially when we consider that the end plates of a battery are of opposite sign to their electrodes or terminals, and that the nomenclature is still further complicated when we come to consider secondary batteries or electrolysis by the terms "anion," "kation" or "cation," and "ions." Take, for example, the definition given by Sprague* of "anode:"—"The positive electrode or pole of a battery; the wire or plate connected to the copper or other negative element of the battery; the plate which leads the + current into a solution to be decomposed, and at which are set free the oxygen, acid radicals and all—ions (anions). In electro-metallurgy it is usually formed of the metal to be deposited, in which case it is called the soluble anode or pole."†

12. Again, we have the two different ways of graphically representing a battery according to the whim or fancy of the writer. Practical submarine



electricians were the first to use this very neat and handy way of representing a battery and its poles, and always adopted the former method, with the long thin vertical line for the plate where the current leaves, and the thick short line for the plate where the current returns to the battery. Why should this have been departed from? It is a mere arbitrary arrangement, but, being a most convenient symbol, it should be used in a uniform manner. Mr. John Munro proposes that the symbol for a secondary battery should be a modification of this, viz.,

the current outside the cell proceeding from the long line to the short one.

13. "Parallel circuit," "multiple arc," "loop circuit," "in loop," "derived circuit," "shunt circuit," are all expressions to signify pretty much the same thing, where one expression, "shunt circuit," would do.

14. "Polarisatian" is a term used in many different senses—for example, the polarisation of battery plates, molecular polarisation due to electrification or magnetisation, polarisation of light due to magnetism, &c., as in Dr. Kerr's experiments. Some reform is required here.

15. Coming to telegraphy, telephony, and electric lighting, we find, as M. Hospitalier points out, "the words generator, receiver, transmitter, and motor are mixed up by different inventors, sometimes through ignorance, sometimes willingly." "A generator is an apparatus which, receiving energy of a certain nature, produces an energy of another nature, and it borrows its name from the nature of the energy which it generates. A receiver is an apparatus analogous to the generator but it borrows its name from the energy which it receives." "A given apparatus is at once a generator and receiver—for example, an electric motor is a generator of mechanical energy and a receiver of electrical energy." "The name transmitter ought to be reserved for an apparatus which, receiving an energy of a certain kind, produces or brings into play an energy of the same kind or of the same form." For example, a relay on a telegraph system, or induction coils as used on a trunk telephone line with several subscribers' lines at each end, or in electric lighting on the Gaulard and Gibbs' system, lately tried in London. Professor Silvanus Thompson uses the phrase "Dynamo-Electric Machinery" in the most general etymological sense of the term, as meaning machinery for converting the energy of mechanical motion into the energy of electrical currents, or *vice versâ*, excepting such induction machines as Holtz, Voss, &c. He thinks this reduces the ambiguity to a minimum, and leaves the word "motor" to be applied, if desired, to the steam-engine, water-wheel, &c., from which the mechanical motion is derived. The terms "magneto-electric machine," as applied to a dynamo fitted with permanent field magnets, and "electro-magnetic machine" to a series, separately-excited, shunt, or compound-wound dynamo (generator or receiver), are very handy expressions, and should not be discarded.

16. We have dealt hitherto chiefly with definitions and nomenclature, and have given a few examples; others will occur to every member present. We now come to abbreviations and notation with symbols. The want of uniformity here, and the need for systematising is still more obvious, but perhaps more difficult to accomplish. Everyone admits the great advantage in being able to write down the symbols for chemical

* Sir W. Thomson calls the magnetic pole of the earth, situated near the geographical north, the "north pole," and the end of the magnetised needle which points towards it, the "*true south pole*" of the needle, and paints it red.

† See Ferguson's "Electricity," second edition, by Professor Blyth, p. 164. The term "electro-kinematics" has been used by Clerk Maxwell to cover a large part of this subject, such as "electric current," "conduction," "resistance," "electromotive force," "electrolysis," &c. (See "Electricity and Magnetism," by Clerk Maxwell, vol. i., part 2.)

* Sprague's "Electricity," 1884 edition, p. 624.

† See Faraday's "Experimental Researches," articles 661 to 667, on *Definitions of New Terms*, where he very clearly points out the meaning he attaches to the words "electrode," "anode," "cathode," "ions," "anion," "cation," etc.

Digitized by Google

elements and their actions and reactions one with the other in the form of simple equations, which anyone may comprehend who knows the subject, without a detailed description of what each letter or symbol stands for. Electricians should not rest satisfied until they are supplied with a similar universally-accepted notation, whereby electrical phenomena and actions may be similarly treated. The author submits a sample of what he considers would be useful in this respect. Many of them are taken from Munro and Jamieson's "Pocket-book of Electrical Formulæ," where an effort was made to use the same notation and abbreviations throughout, except in such cases as that of quoting direct from some other author.

It will be observed in this list that in most cases the first English or Greek letter of the word has been used. Those relating to the metric system have been copied from the French edition of Hospitalier's "Electrician's Pocket-book," which are no doubt copied from the list decided upon by the International Commission on the Metre, with a few omissions and additions by the author.

The Greek letters π, μ, ϵ are universally adopted—π for the ratio of the circumference of a circle to its diameter, μ for the coefficient of friction, and ϵ for the base of Naperian logarithms.

Metric Abbreviations.

m.	for	metre.
cm.	,,	centimetre.
mm.	,,	millimetre.
m.q.	,,	metre-square.
m.c.	,,	metre-cube.
c.q.	,,	centimetre-square.
c.c.	,,	centimetre-cube.
gm.	,,	gramme.
mg.	,,	milligrammæ.
k.g.	,,	kilogramme.
kgm.	,,	kilogrammetre.
&c.		&c.
temp.	,,	temperature.
res.	,,	resistance.
g.d.	,,	gramme-degree.
kg.d.	,,	kilogramme-degree.

Electrical Abbreviations, Notation, and Symbols.

When a capital letter is used for the symbol, then small capitals or italics with suffixes, 1, 2, 3, &c., may be used for parts making up a whole. For example—L for length, L_1, L_2, L_3, &c., or l_1, l_2, l_3, for different lengths, or parts of L.

Fundamental and Derived Mechanical Units.

L	for	Length.
M	,,	Mass.
T	,,	Time.
V or v	,,	Velocity.
A or a	,,	Acceleration.
F	,,	Force.
δ	,,	dyne; *e.g.*, 10 δ = 10 dynes.
W	,,	Work.
w	,,	weight.
ft. lb.	,,	foot pound.
H.P. or HP	,,	Horse-power.
I.H.P.	,,	Indicated Horse-power.
B.H.P.	,,	Brake Horse-power.

Other Common Symbols allied to Mechanical Work.

S	for	Speed or Stress.
D or d	,,	Diameter.
r	,,	radius.
ω	,,	angular velocity = $2\pi n$ in radians per second.
g	,,	acceleration due to gravity.
N or n_1 n_2, &c.	,,	number of revolutions.
$-^s$	,,	second; *e.g.*, 3^{hr} 5^m 10^s = 3 hours 5 minutes 10 seconds.
$\tau_1\tau_2\tau_3$, &c.	,,	temperatures, absolute.
or $t_1°t_2°t_3°$, &c.	,, ,,	common.

Practical Electric Currents.

The astronomical method of putting the small letters above the line of the figures, as in the case of the example 3^{hr} 5^m 10^s (3 hours 5 minutes 10 seconds), has not been followed in the following examples, as mathematicians object to the system, the letters appearing as if they were powers. Neither will they readily agree to suffixes, as suffixes have been already adopted by them to distinguish between things of the same kind. The author has therefore written the distinguishing letters on a level with the figures: for example, 10ω stands for 10 ohms (the methods 10^ω and 10_ω being both objectionable).

C.G.S.	for	centimetre, gramme, second.
R	,,	Resistance.
ρ	,,	specific resistance.
ω	,,	ohm; *e.g.*, $10\omega = 10$ ohms.
Ω	,,	megohm; *e.g.*, 10Ω = 10 megohms.
C	,,	Current.
A	,,	amperes; *e.g.*, 10A = 10 amperes.
a	,,	milliamperes; *e.g.*, $10a$ = 10 milliamperes.
E	for	Electromotive force or E.M.F.
v	,,	Volts; *e.g.*, 10v = 10 volts.
K	,,	Capacity.
σ	,,	specific inductive capacity.
Φ	,,	farads; *e.g.*; 10Φ = 10 farads.
ϕ	,,	microfarads; *e.g.*, 10ϕ = 10 microfarads.
Q	,,	Quantity (coulombs).
P	,,	Power.
WP	,,	Watts or Watt power.*
W	,,	Work in Joules.
H	,,	Heat in ,,
J	,,	Joule's equivalent = 42×10^6 ergs, or work spent on ·2405 gm. of H_2O raised by 1° cent.

$$C = \frac{E}{R} \text{ (Ohm's law).}$$

$$E \times C = C^2 R = \frac{E^2}{R} = WP \text{ (Watt powers).}$$

$$ECT = C^2RT = \frac{E^2T}{R} = EQ = W \text{ (Joules).}$$

$$\frac{ECT}{J} = \frac{CRT}{J} = \frac{E^2T}{JR} = \frac{EQ}{J} = \frac{W}{J}$$

$= W \times \cdot2405 =$ g.d. or gramme degrees.

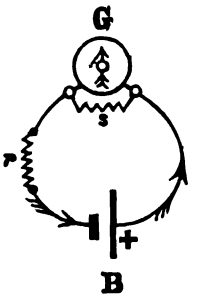
z = Electro-chemical equivalent.

Magnetism.

N	For	North pole of a magnet, painted red.
S	,,	South ,, ,, painted blue.
m	,,	magnet strength (of pole) or quantity of magnetism.
l	,,	distance between the poles of a magnet.
M or ml	,,	moment of a magnet.
$\mathfrak{F}$ or I	,,	intensity of magnetisation.
s	,,	cross section of a magnet.
mp	,,	magnetic potential.
μ	,,	magnetic permeability.
κ	,,	magnetic susceptibility.
H	,,	horizontal intensity of terrestrial magnetism.
θ	,,	angle of deflection.
d_1 d_2 d_3	,,	divisions deflection, as in mirror galvanometer.
r	,,	radius (mean) of a coil or solenoid.
n	,,	number of anything; *e.g.*, turns of wire in a coil o galvanometer.

Take Tangent Galvanometer Formulæ, as an example to illustrate the above:

$$\text{Current, } C = H \frac{r}{2\pi n} \cdot \tan\theta.$$

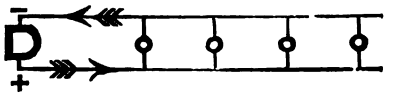


G	for	Galvanometer or galv. res.
s	,,	shunt res. for galvanometer
r	,,	resistance coils
B	,,	Battery or battery res.

$$\therefore R = B + \frac{G S^1}{G + S} + r\dagger$$

Dynamo Circuits Contractions.

Example:



D	for	Dynamo.
T+	,,	Terminal positive.
T−	,,	Terminal negative.
E.M.	,,	Electro-magnet.
or F.M.	,,	Field Magnet.
c.p.	,,	candle-power of a lamp.
A.M.	,,	Ampere-meter.
V.M.	,,	Volt-meter.
S.W.G.	,,	Standard wire gauge.

* By adopting the term "Watt power," there can be no doubt what a Watt means.

† See Munro and Jamieson's "Electrical Pocket-book," p. 65.

Digitized by Google

For use in Formulæ.

R_a R_m R_e for Resistance of armature, magnets, and external circuit respectively.

C_a C_m C_e ,, Current in armature, magnets, and external circuit respectively.

L_s ,, coefficient of self-induction.

L_m ,, coefficient of mutual induction.

In the above notation the first letter of the most important words has been used wherever it was found practicable to do so, and the recurrence of the same letter under similar circumstances avoided as much as possible. In cases where no ambiguity can occur, such as H for the heat in Joules, and H for the horizontal intensity of the terrestrial magnetism; m for metre, and m for magnetic strength of pole; V for velocity, and v for volts, it will be observed that the same letters appear in each case.

A discussion followed the reading of the above paper, M. HOSPITALIER, who had come from Paris for the express purpose, leading off with a series of sharp criticisms on Mr. Jamieson's proposals. M. Hospitalier stated that the committee in Paris had already made some progress in devising a scheme of notation and nomenclature such as might form the basis of an international system. Nothing of the kind could be expected of Mr. Jamieson's scheme, which proceeded on no definite principles, and was often contradictory, arbitrary, and hard to remember. Prof. FORBES, Prof. AYRTON, and others followed, their general verdict being unfavourable to Mr. Jamieson's paper. The president, Mr. SPAGNOLETTI, announced that the society had had under its consideration the desirability of arriving at some international understanding on this subject, and had that evening decided to form a committee for its investigation. The committee in the first instance would be a broad one, and not confined to members of the society.

PHILADELPHIA EXHIBITION.

(Concluded from page 380, Vol. XIV.)

THE DELANY CABLE.

("C." of the Section's Classification.)

This cable may comprise any number of conductors desired, and of any size required. When a single conductor is used, a bare or cotton-covered wire, insulated in any of the usual ways, is threaded through small discs or buttons of vitreous material, such as porcelain or glass, so that the conductor throughout its entire length is covered by the incombustible buttons which are about half an inch in length and one-eighth of an inch in thickness. The conductor thus surrounded is passed through a compound of insulating material and through a lead press machine, which encloses the whole in a lead covering or pipe, so that, when finished, the cable or conductor is first enclosed in a braided covering saturated with an insulating compound, then surrounded by the incombustible discs or buttons, again covered with an insulating compound, which is forced in hot as the lead pipe is formed around it. The latter filling occupies all the interstices and space between the conductor and the vitreous buttons and between the buttons and the pipe, thus leaving no air spaces, and thereby preventing condensation of moisture. The incombustible material separating the conductor from the pipe renders the transmission of the most powerful currents absolutely safe, since under no circumstances can the conductor come in electrical contact with the pipe. Should the conductor become heated the soluble insulating compound would be united more firmly, closing up any cracks that might have occurred from low temperature or contraction.

When a series of conductors are used they are all threaded through separate holes in the same disc or button, and thus mechanically separated from each other, and from the pipe in which they are enclosed.

This cable is practically indestructible, as its durability is only limited to that of the enclosing pipe, which may be of lead or iron. When lead is used the cable may be constructed in lengths of one-quarter or half a mile without splicing, and coiled on a reel, the vitreous discs admitting of flexing to any extent necessary,

The conductors cannot become crossed, nor can they be grounded so long as the enclosing pipe remains intact. As the lead pipe is formed around the cable in a molten state, there is no seam, weld, or joint throughout the entire length in each section.

All danger from fire in buildings is obviated. Rats cannot destroy the insulation, and the cable may be laid in chimneys, ventilation or heating flues, or placed in the walls like gas or water pipes, with perfect security against interruption or damage, or the necessity for tearing out the walls for repairs of any kind.

Three tests of this cable were made at the International Electrical Exhibition, for the purpose of ascertaining the effect of powerful currents on the insulation. These tests were made under the direction of Capt. de Wolski, Chairman of the Committee on Underground Conductors. The first consisted of placing a piece of cable about five feet in length so as to short-circuit the Hochhausen electro-plating dynamo machine. This conductor, a single one, insulated as described in the beginning, was No. 4 Birmingham gauge copper wire. The dynamo machine had an electromotive force of two and one-half volts. A current of 600 amperes was passed through the cable for 20 minutes. The conductor was made red hot, but the insulation was uninjured, the melting of the filling-in compound being the only result of the experiment.

The second test was similar to the first, with this difference in the current—800 amperes were sent through the cable for 20 minutes. The wire became so hot that the vitreous discs surrounding it melted the lead covering, leaving the insulation uninjured.

The third test was with the conductor inclosed in an iron instead of lead covering. When sufficient current could not be passed through the conductor to cause any effect other than the melting of the filling compound and charring of the braided covering on the wire, the conductor was perfectly secure in its insulated separation from the pipe and consequently free from all danger.

This single conductor, insulated and inclosed as described, ready for use in the ground or elsewhere, can be furnished for 22 cents per foot. Six separate conductors of No. 16 copper wire, for telegraph or telephone use, and covered in a like manner, will cost the same amount.

INVENTORS' INSTITUTE.

At a meeting of this Institute on Monday evening, Mr. C. E. Spagnoletti in the Chair, a paper "On Electric Tramcars" was read by Mr. A. Reckenzaun. The author said that whilst a single electric tramcar only existed in this country, a paper on the subject might be thought premature. This solitary example is, however, the latest and only practical form; and the Institute has the privilege before other societies of judging of the merits of an invention, as an invention, apart from commercial aspects. After a comparison of horse, steam and compressed air traction with electrical traction, the difference of the electric tramcars from electric tramways and railways was pointed out to be that, whereas in electric tramways the energy is conveyed from the generating station to the rails or other conductor communicating with the motor which turns the car wheels, the electric car carries its own energy within itself, and is quite independent of external influence, and the car can travel over any road or rail for whatever system, ordinary or specially designed. The original Faure battery has never been of practical use, and very substantial improvement had to be made at enormous expense to bring the secondary battery to a commercial value. The Electrical Power Storage Company having acquired the patents of Sellon, Swan, and Volckmar in addition to Faure's, have step by step improved the mechanical details of the storage batteries, until they have arrived at a thoroughly practical article; but the prejudices created in the public mind by the early failures are now encountered and have to be overcome. The cell for the tramcar is contained in a lead-lined strong teak box. In it are placed 21 lead plates, weighing together 26lb., including terminals and fittings. Sixty such cells, weighing one ton and a quarter, are required to propel a car with 46 passengers for about two hours over a road with ordinary gradients, curves, and 60 stoppages per hour. A diagram was shown representing the car which has been running at Millwall and Battersea. The electric motor has to convert the electric current into mechanical power. For tramcar propulsion, it is absolutely necessary that the motor should have high efficiency, and at the same time be of small dimensions and light weight. The author's machine has these qualifications. For the car there are two motors, each capable of working up to nearly nine horse-power, and weighing 420lb. Each motor is carried separately upon a small bogie, in such a way that each bogie forms a small locomotive engine upon which the car rests. One axle of each bogie is a driving axle; thus are actuated four small driving wheels. The speed of the motors is high, about 1,000 revolutions per minute when the car is running at seven miles an hour. Thus it is necessary to introduce reducing gear between the motor shaft and the driving axle. The gearing employed is a worm on each motor shaft, and worm-wheels on the driving axles, giving a ratio of about one to twelve. This worm-gearing is cased in, and the wheels work in oil, the lubrication being perfect. The variation of speed and power is obtained by means of a compound switch, which arranges the motor circuits so that the machines shall work in series, in parallel or singly; thus the resistance of the circuit being varied, the power and speed vary accordingly; when a greater range of speed is desirable the motor circuits are still further divided by arranging the field magnet wires apart from the armatures. This obviates cumbersome gearing which would add to the weight and the expense, increasing first cost and the maintenance as well.

Brake power, both mechanical and electrical, is efficiently applied The most economical steam tramway locomotives burn from nine to eleven pounds of coal per mile. The coal for charging the electric tramcar batteries amounts to four pounds per indicated horse-power. Reckoning the coal at eighteen shillings per ton the fuel per car mile would be less than one penny.

An interesting discussion followed, in which Prof. Geo. Forbes, Mr. Traill, Mr. Shoolbred, Mr. Drake, and others took part, the improvements made by Mr. Reckenzaun being thoroughly recognised.

LEGAL.

The Duplex Telegraph System.

Yesterday the House of Lords gave judgment in the appeal of the Direct United States Cable Company *v.* Muirhead and others. The question in the case was as to whether the Cable Company should pay a royalty of £2,000 per annum under an agreement, they having ceased to use it, owing to the telegraph cable having got into such a state that the duplex system could not be applied. It appeared that the patentees of the duplex system, Messrs. Muirhead, entered into an agreement with the Direct Cable Company to receive £2,000 per annum as royalty on the duplex system of telegraphy "operating satisfactorily" on the line of the company. The Direct Company had only one line, but it was contemplated that there should be four lines, and Messrs. Muirhead were to receive something additional on its being applied to the other lines. In consequence, however, of a former arrangement the Direct Company had the advan-

Digitized by Google

tage of sending over another line, and so the simplex system was continued. The line, too, of the Direct Company had got into a state unfitted for the application of the duplex system. The case originally went before Baron Huddleston, and then to the Court of Appeal, who decided against the Direct Company, who now appealed to the House of Lords. Their lordships present were the Lord Chancellor, and Lords Blackburn, Watson, and Fitzgerald.

The Solicitor-General for Scotland and Mr. W. A. Hunter appeared for the Direct United States Company; and Mr. Webster, Q.C., and Mr. Moulton for Messrs. Muirhead.

It was contended for the appellants that, though the duplex system had operated satisfactorily for five years, they were, when the line got into such a state that it could not be applied, entitled to cease the payment of the royalty.

For the respondents it was argued that the whole scope of the agreement showed that what was contemplated was that, as soon as the duplex system was proved to be successful as a system then the respondents were bound to use it and pay the royalty.

The LORD CHANCELLOR in giving judgment said that the decision of the Court below ought to be affirmed. The recital of the agreement, after mentioning that the Direct Company were the owners of a certain line of telegraph cable, proceeded thus: "Whereas the company have proposed to the patentees to apply to their cables the system of duplex telegraphy of the patentees." Now, that application of the system to the company's cables was the object of the entire agreement. The first Article said that "the patentees grant to the company a license to use the inventions in question, so far as they regard the duplex working of telegraphs, and any improvements in and upon or in connection with all or any cables or lines connected with the telegraph cable which they do possess." That was that they purchased a license to use these cables and telegraphs; and it appeared to him that the company were responsible for providing the cables and maintaining the mechanism which they were to lay down necessary for working the duplex telegraph invention. If they did not provide cables of the proper kind, to be judged by reasonable and skilful men, then they would not carry out that part of the agreement which depended upon them. The company must therefore provide two things: cables, to which the system of duplex telegraphy was to be applied, and the mechanism of the duplex telegraphy itself; and they should not only provide these things, but maintain them in a proper state to enable them to get the benefit which they stipulated for from the use of the invention; and he should have thought, independently of any evidence almost, that it was essentially involved in the idea of cables that there should be a proper continuity for the purpose which both parties had in view. He could not conceive how the rights of the patentees were to be taken away merely because the company did not choose to do that which it was incumbent upon them and not upon the patentees to do. By the 11th Article the patentees were in effect to assist to bring into original operation their duplex system on any of the company's cables when required on certain terms. The patentees had done that some years ago. Then the 2nd Article said that as long as the license was in force "the patentees shall and will render to the company, their successors, and assigns, all instructions, advice, and assistance to enable the license to be used to the utmost advantage, at the expense of the company." It was not alleged in this case that the patentees had not complied with this term of the agreement, and everything that the patentees were to do had been fully and completely done. Then the 3rd Article was the clause upon which the question turned. It provided for the consideration of the license—the money payment. That money payment was to commence and to be payable from the date when the patentees "shall have supplied their duplex system to the company's line, and shall be considered as accruing and due from day to day, and apportion it accordingly; and that payment so commencing is to continue during the continuance of the license, and whilst the duplex system of the patentees shall operate satisfactorily, subject as hereinafter provided." Now the first thing to observe was that it was not said, "whilst the mechanism laid down for this duplex system is actually connected with the cable in its actual state for the time shall operate satisfactorily," but "whilst the duplex system of the patentees shall operate satisfactorily." The system was a perfectly different thing from the mechanism which the company and not the patentees laid down and had to keep in order for the purpose of using it, and though no doubt it was involved in the idea of the words "operating satisfactorily" that it should be applied to the company's cables, yet, on the other hand, that condition was satisfied if the operation of the system was satisfactory, and it carefully abstained from making that dependent upon what he might term the accidental condition either of the mechanism for the use of the system or of the cable to which it was to be applied, and for both these the company and not the patentees were responsible. If these words stood alone he should infer that if the fault was not in the system, but in the manner in which the company thought proper to use or not to use it, that the payment was not to stop merely because of those words, "whilst the duplex system shall operate satisfactorily." The whole context of the agreement showed that the payment was not to stop in that event. There were certain stipulations as to when the payment was to be suspended. Article 6 showed that the mere voluntary non-user of the invention on the ground that something else might be more for their commercial advantage was not to be a thing which in itself would suspend the payment, or to which the words, "whilst the duplex system of the patentees shall operate satisfactorily," could be applied, because Clause 6 provided, in the case of any better invention of the same kind recommending itself to the company, that certain things were to be done which might or might not terminate in relieving the company from liability. They first must give notice; then they must in substance give the patentees the opportunity of producing the same effect in as advantageous a manner, and if they did not then the company might be relieved from the payment, therefore making it most clear that if the thing did not operate satisfactorily, merely because the company did not choose to let it operate at all, even for reasons which turned upon their commercial advantage and benefit, that the payment was nevertheless to go on. As to Article 5, he did not think it necessary to go into any question as to the precise event, but taking it that if in a certain manner there was a total interruption of communication of the company's cable between London and New York, then the payment was to cease during the period of interruption. Why was that put in? He should say because, if it had not been put in, and if the patentees and their system had not been in fault, then the liability in the view of both parties would have continued. But if the liability had continued in the case of total interruption, then there was nothing for which the royalty could be obtained, and the fact of there being no similar provision made for a partial interruption, the inference was that it was to go on. Now, what were the actual facts of the case? They were these. A certain amount of continuity and insulation was required for the proper operation of that kind of cable to which this invention was to be applied. It was admitted that there were such serious faults—that there was such a serious breach of continuity and insulation in the case of this cable in the deep sea, that some times there were interruptions of variable duration and importance continually occurring, and that it did not work properly even as a cable for what was called the simplex system. It was capable of transmitting the messages, but not with the rapidity, or certainty, or clearness which it ought to do if in proper order. It was confessedly out of proper order, and he should say out of that sort of order which everybody must be considered to have had in view when the application of this simplex system was made. Who was responsible? Of course the company, because it did not suit them to go to a large expenditure for the purpose of putting that right, the patentees being in no fault whatever, and their system having operated for five years quite satisfactorily until this fault in the company's cables took place, and that being a fault which the patentee did not profess by his patent to be able to remedy. It was agreed by both sides that the duplex system was inapplicable to a fault of this magnitude, and that being the case, it appeared to him that within the true and natural meaning of the contract, and according to good faith, the event had not arisen in which the company was entitled to say that the system of the patentees was not "operating satisfactorily." He therefore agreed with the judgment of the Court below, and he advised their lordships to dismiss the appeal, with costs.

Lord BLACKBURN said he perfectly agreed with the judgment of the Lord Chancellor. The words they were to construe were that the company were only to pay whilst the duplex system of the patentees "shall operate satisfactorily." The parties probably had in their minds what James Watt said of some inventions, that they were mere toy models, and they might consider that if it operated satisfactorily then they would be willing to pay £2,000 a year. They began working in April, 1867, and it had worked satisfactorily for five years; and he could not think that the system had ceased to operate satisfactorily merely because the cable got so far out of order that it no longer operated satisfactorily upon the cable. But he would go further, and say that if the system worked satisfactorily, and if the line were injured and it would cost more to bring it into a state of repair to use the duplex system, still the company would be bound to pay.

Lords WATSON and FITZGERALD agreed.

The appeal was dismissed with costs.

Gandy v. the Gulcher Electric Light and Power Company.

This was an appeal before Lord Coleridge and Mr. Justice Cave, on Friday last, by the plaintiff for a new trial, or that judgment might be entered for the plaintiff for a sum agreed upon, on the ground of misdirection, and that the verdict was against the weight of evidence.

It appeared that the plaintiff in April of 1884 offered to supply the defendant company with some belting for six months for the purpose of driving their dynamos at the Crystal Palace, for the consideration of his being allowed to place a board notifying that the belting belonged to him in the space allotted to the Gülcher Company, by way of advertisement. The offer was accepted, with the condition that the board should meet with the approval of Mr. Wallace, one of the company's directors. Shortly afterwards the board, which was 20ft. long and 4ft. high, was put up at the Palace by the plaintiff without its having been seen by Mr. Wallace. It had, however, only been up a few hours when the manager of the Crystal Palace came and ordered it to be taken away, on the ground of its not belonging to the Gülcher Company, but to an outsider, who, if wishing to advertise, must pay for advertising space. The board was accordingly removed, and a meeting between the parties took place. Mr. Gandy proposed that the bargain should be dropped, but the company objected and offered to pay £60 for the use of the belting for six months from the 1st of May, which offer the plaintiff refused to accept, demanding another £15 for the cost of the board, and no arrangement was come to. The plaintiff afterwards sent to fetch his belting away, but the defendants refused to give it up, and went on using it till the end of the six months, when, as they refused to pay anything for the use or to purchase it outright, Mr. Gandy commenced proceedings against them. The trial came on for hearing before Mr. Justice Wills and a jury, with the result that a verdict was returned for the defendants upon the ground that there was no agreement, the plaintiff not having complied with the condition of getting Mr. Wallace's approval to the board.

Mr. French appeared for the appellant, and Mr. Kingscote for the respondents.

Lord COLERIDGE was of opinion that a verdict should be entered for the plaintiff. It appeared to him that there was a contract entered into

Digitized by Google

between the parties, the performance of which was prevented by an obstacle the arising of which was contemplated by neither party when it was entered into. That being so, he thought that as the defendants had had the use of the plaintiff's belting they must pay for it on the "quantum meruit." It had been agreed that the "quantum meruit" should be £50; therefore their judgment was that the verdict should be entered for the plaintiff for that amount.

Mr. Justice CAVE concurred.

Mr. KINGSCOTE asked what order their lordships would make as to costs. The defendants had made an offer of £60 on the 26th of May.

Lord COLERIDGE said they were both of opinion it was a case for no costs.

COMPANIES' MEETINGS & REPORTS.

The West India and Panama Telegraph Company (Limited).

The sixteenth ordinary general meeting of the members of this Company was held at the City Terminus Hotel, Cannon-street, on the 20th inst, under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) having read the notice convening the meeting, and the minutes of the last meeting, which were confirmed, the report of the Directors was taken as read.

The CHAIRMAN: The accounts which we present to you to-day show a decrease in the gross revenue for the half year of £4,235 in comparison with that of the last corresponding period; but that is in comparison with an abnormal half year, in which we had over £5,000 increase. It was a half year of windfalls. We chartered one of our repairing ships to an American company, which brought us in some profit. Then there are some other details which account for the decrease of the present year. For instance, there is the interest upon the reserve fund, which is now carried to the reserve fund instead of to the credit of revenue, and there were some arrears of subsidy which in the corresponding half year became payable, and which do not appear in the present half year's accounts. There is nothing in the working of the concern at all which has caused the falling off in the gross revenue. It is entirely a matter of accounts, I may say, in comparison with an unusual period. The same state of affairs influences the expenditure side of the account. We have an increased expenditure of £5,400, but that is comparing it with a period in which there was £6,075 decrease over the then corresponding period. In that half year—the half year ending 1883—the ships were first of all taken off our hands, as far as expenditure goes, by the International Ocean Telegraph Company chartering one of them, and we brought one of our vessels home for repairs and over-hauling. That ship took out a cargo of cable, the freight of which was credited to the ship, and so the expenses of that half year were materially reduced. There is nothing in the expenditure of the present half year which is abnormal, and our business was conducted at very much the same cost as before. As to the subsidies, the report states pretty fully what the position is. When I last had the pleasure of addressing you we were in negotiation with the three colonies of Barbadoes, Guadaloupe, and Martinique for a renewal of their subsidies. I am happy to say that they have all renewed for various terms—Guadaloupe for ten years, Martinique for five years, and Barbadoes for only three years. The renewal of the St. Thomas subsidy has not yet been settled, though it expired the 31st December last. I met the governor of the colony, which you all know is a Danish colony, while he was in London, and he explained to me, or rather impressed on me, what I had known before, that the colony was in a very poor condition as to finances. It appears that its supremacy as the great shipping port of the West Indies has vanished, and the cause of their losing that supremacy is the existence of the telegraph. The telegraph has benefited very much the other colonies at the expense of the shipping of the colony of St. Thomas, and the governor told me that it was not possible for them to continue the same amount of subsidy which they had been hitherto paying—£1,000 a year. He made certain proposals for our doing a little more work for a little less pay, as usual, and I am in hopes that we shall have a renewal of that subsidy, though I am sure it will not be on the same terms as before, but perhaps at a diminution of £200 a year. I am sorry that the colony of Barbadoes still stops the way with regard to an increase of the subsidies. But it appears from what I have heard, not only from the governor of St. Thomas but from others, that what the island of St. Thomas has lost through the telegraph Barbadoes and some other colonies have gained; and yet while we are mulct to a certain extent of the subsidies payable by St. Thomas for instance, because some of its trade has gone elsewhere, we get no increase from Barbadoes, which has been the gainer. In all these questions, however, we must be ruled by the possible, and we all know the severe depression through which the West Indies have gone. [He then quoted an extract from the *European Mail*, and continued.] When we complain of the treatment of the colonies it is well to bear in mind what a very depressed condition they are in. Supposing it is true (and it is so stated in that excellent paper) that the Government officers themselves are only paid their salaries by driblets, one can hardly expect just now that they should increase our subsidies. The sugar market—sugar is the great staple of course of the West Indies, and its ups and downs very much affect us—is improving. I find that Muscovada sugar was quoted at 19s. 6d. per cwt. in 1882, while at the end of last year it was down to 10s. 3d. At the present time it is 14s. 6d.—perhaps a little better, as yesterday there was a rise—so it is going on towards half-way recovering the great fall it had, and I hope that our affairs will improve in the same ratio. In fact our traffic returns for the current half year are about 6 per cent. increased on those of the corresponding period of the previous year. Perhaps the most important part of the report that we are discussing to-day is the repair of the cable between Jamaica and Porto Rico. That was laid in 1871, before this Board took office. It was never, I believe, a very effective cable in those days. In 1873 a cable was purchased and intended to be laid between Jamaica and Colon, but, very fortunately for us all, it was diverted by the late Board so as to run between Jamaica and Porto Rico, instead of between Jamaica and Colon. The Jamaica and Colon cable, which was then thought hopeless, has since operated very regularly. It was only at the end of 1884 that we were able to restore the original cable between Jamaica and Porto Rico. We have been several years at work on that cable. I think we began in 1881 to seriously examine and effect repairs on it. It was only when the ships were not engaged in more pressing work that we could proceed with the restoration of this very important section, and after a very persistent, troublesome, and expensive course of operations the cable was restored in October last year, and it has worked very satisfactorily ever since. I think that great credit is due to the officers and crew of the ship that was at work. One is apt to talk very glibly of repairs seated here comfortably in London, but if one could carry one's imagination to the long days under a tropical sun, and picture men trying to find a cable, perhaps 1,200 or 1,500 fathoms deep in water, enduring the disappointments and vexations that must occur to those engaged through a very long time in such work, I think you will agree with me that those men deserve our thanks. We are now bringing our second ship, our smaller vessel, home to be refitted. She has been out some years in the West Indies. She was not new when we bought her, and her boilers are giving some symptoms of wearing out. We want some more cable in the West Indies for repairing purposes, and we thought this year a very good opportunity for bringing her home to be overhauled and to take out this cable. I should be very happy to answer any questions you may ask, but meantime I will move, "That the report and accounts to the 31st December, 1884, submitted to this meeting be, and the same are hereby received and adopted; and that, as recommended by the Board, a payment of 6s. per share on account of arrears on the first preference shares be, and the same is hereby declared."

Mr. WM. FORD seconded the motion.

Mr. NEWTON thought that the operation which had been accomplished of repairing the original cable between Jamaica and Porto Rico was exceedingly important to shareholders in telegraph companies, as inspiring them with confidence in the substantial character of their property, and therefore he thought that the fact of such a repair having been effected should be emphasised. He also considered that it might be regarded as a splendid advertisement for Messrs. Silver. He desired to know the present condition of the cable, and the type of the new cable put in.

The CHAIRMAN, in reply, said they quite appreciated the value of the repairs which had been effected, as it had given the Company a duplicate line over the most important part of their system. The quantity of new cable put into the old cable was 232 miles out of a length of 700 miles. He did not mean to state that the cable was in a very high electrical condition, but he supposed that it was in as high electrical condition as most of their cables out there. It was in very good working order, and it had given them no trouble since it was repaired last October. The type of cable with which it was repaired was identically the same as the original cable. It was a sheathed cable. The benefit of the repair had already been felt during two interruptions of the duplicate cable, as the line that was restored last October carried all the work. He had not meant to say that the construction of the cable which had been repaired was not good, for he believed it was as good as any, but it was not skilfully laid. There was no doubt that if the late Board had not diverted the cable which had been meant to be laid down between Jamaica and Colon, and laid it between Jamaica and Porto Rico, the Company would have been in a very great difficulty, for they would have lost the connection for some time with all the islands in the Antilles to the eastward, and all the subsidies.

A SHAREHOLDER asked if any idea had been formed by the Directors as to the effect on the Company of the opening of the Panama Canal.

The CHAIRMAN thought it was very difficult to speculate on such a matter. It would be a long time before it was opened; but when that occurred he should imagine that it would have a great influence on the trade of the region, and that the Company must share in any benefit that arose in that way.

Mr. BAKER said that a large amount was due for arrears on the preference shares, and thought that the Company would be in a very much better condition if some second preference shares were issued in payment of arrears on the first preference shares. As to the £50,000 of 6 per cent. debentures, their reserve fund was now invested at 4 per cent., and he thought it would be a very good thing to invest a portion of the reserve fund in paying off the debentures, which would save £1,000 a year. He really believed that something should be done now with a view of improving the position of the original shareholders.

The CHAIRMAN said that the 6 per cent. debentures were due at the end of next year, and that they could do nothing with them until they became due. When they matured, the Directors no doubt would be able to make some other arrangements; but as to paying them off, unless the money were taken from the reserve fund, he did not know how that proceeding could be accomplished.

A SHAREHOLDER: Pay them off, as the Direct United States Company did theirs, out of the reserve fund.

Mr. FORD: The Direct Company had an ample reserve fund.

Mr. WM. ANDREWS observed that the shareholders might take it that they had not more than an adequate reserve fund.

The CHAIRMAN, in further reply to Mr. Baker, stated that great difficulty was experienced on the last occasion in capitalising the arrears. He

Digitized by Google

was open to any suggestion, but his feeling was that until their revenue was a little better they could not bear an increase on the fixed charges. Indeed, it was rather by the skin of their teeth they paid the fixed charges at present.

Mr. NEWTON thought it might be possible to do as the Direct Company had done, and pay off the debentures out of the reserve fund; but as to capitalising their arrears that was impossible, in the opinion of Mr. Horace Davey, whom he had consulted in connection with another company as to capitalisation of arrears.

Mr. CHAPMAN asked whether the Chairman could hold out some hope to the shareholders by mentioning a limit for the reserve fund.

The CHAIRMAN said he did not like to commit himself as to the extent to which they were going to continue the reserve fund. They had a certain basis, formed on the presumed life of a cable, and the rate of interest they could get on securities of a good class; but he thought he could say in a very short time the contributions would be less annually than they were now—he might say considerably less. But a reserve fund which was really a depreciation fund could never be quite closed.

The resolution was then put and carried unanimously.

On the motion of Sir JAMES ANDERSON, seconded by Mr. HENRY HOLMS, Mr. Earle was re-elected a Director, and Mr. Ford was also re-elected to his seat at the Board on the motion of the CHAIRMAN, seconded by Mr. ANDREWS.

Mr. FORD said he desired to thank the shareholders for the renewal of confidence which they had shown in re-electing Mr. Earle and himself, a proceeding by which they had, he thought, expressed their confidence in the whole of the Board. The present Board were elected ten years ago, and he occasionally met some shareholders who asked him was there any hope for the Company, and the solace he gave them was derived from facts—that was from a comparison of the position of the Company in 1874 with the position of the Company in 1884, at the close of the financial year with which they were dealing at that meeting. The income of the Company in 1874 was insufficient to pay its working expenses, being £28,394, while for 1884 it was £91,660. What was their position as to the subsidies? In consequence of the inefficient service which the Company at that time gave, the subsidies amounted to £2,125, whereas in 1884 they received on that head £22,915. Not only had they succeeded in obtaining the full amount of the subsidies, but they had obtained something more—a renewal of them for further periods. With regard to the means of the Company for effecting repairs, when the present Board took office they had a paper ship, the "Suffolk," which, he believed, involved the previous Board in a loss of £24,000. They had now instead of a paper ship two efficient repairing steamers—the "Grappler" and the "Duchess of Marlborough"—which the Company had provided out of the revenue at an expense of £30,000 or £35,000. As the shareholders were aware, the strength of a telegraph company consisted in the duplication of its lines. When, however, the present Board came into office, they had not a single duplicate line, whereas they had since added 870 miles of duplication. As to the question of dividend, up to 1874 not a farthing had ever been paid to the shareholders, but they had since paid altogether £157,587. Ten years ago they were in litigation, and the first act which the present Board was called upon to perform was practically to draw a cheque for £8,000 to meet the expenses of counsel's fees upon the suit then pending between the Company and the India Rubber Company. They settled that litigation, and succeeded in striking off the capital account no less than £181,000; but what was still more important was this. In 1874 the Company was practically insolvent, not having a farthing of reserve fund, but in 1884 they had £105,214 in hand with which to keep up their system, so that its continuance was, in his humble opinion, practically secured. That was the account which he ventured to give on behalf of his colleagues, without whose able assistance it would have been impossible to effect such results. When, therefore, he was asked what hope there was for the future, he asked those who put that question to read the answer by the light of information which the facts he had given them afforded.

Mr. J. G. GRIFFITHS having been re-elected to his position of auditor, a vote of thanks to the Chairman and Directors was passed on the motion of Mr. Newton, and the proceedings terminated.

The Consolidated Telephone Construction and Maintenance Company (Limited).

Report of the Directors to be presented at the fourth general meeting of the Company, to be held at the Cannon-street Hotel, on Tuesday, 26th inst., at 12 noon:—

According to the revenue account the amount standing to the credit of profit and loss is £5,208. 18s. 4d., and the Directors recommend that this amount be carried forward to the next year's account. It will be recollected that at the meeting in December, 1884, it was decided to write off to capital account the sum of £7,500 from the balance of revenue account 1883-4, viz., £10,290. 17s. 9d., and the remainder has been written off the valuation of stores on hand on the 31st March, 1884, the amount being considered in excess of their value. In accordance with the resolution passed at the adjourned general meeting in December, 1884, the capital account has been reduced to £243,787. 10s., of which £168,637. 10s. is issued, and the same has been sanctioned by the Court of Chancery. The relations between the United Telephone Company and your Company continue of a satisfactory nature. Your Directors are happy to state that the manufacturing business has decidedly increased, and that with the extension of the radius granted by the Postmaster-General to the United Telephone Company and its subsidiary companies, a new life seems to have been given to telephonic enterprise, and considerable orders have been executed for the United Kingdom. There is on hand at the moment, amongst others, a most substantial order from the United Telephone Company on behalf of the Postmaster-General. Sample telephones have recently been submitted to the War Office (for use abroad), to the Postmaster-General of Melbourne, and to the Spanish Government, and good results may be looked for in these quarters. There is also under the consideration of the Board a large order for Canada. The shareholders will read with satisfaction that the "Consolidated" telephone is highly approved by the Canadian Government, which has recently favoured this Company with an order; and also by the authorities working the Sydney Exchange, and in many other places. In addition to the orders received from your subsidiary companies in Austria, Portugal, and the River Plate, several orders have been received from the Continent, and it is hoped that in course of time these may be greatly extended. The business of the several subsidiary companies in which this Company is largely interested continues to make very satisfactory progress. The Telephone Company of Austria at the end of March, 1884, had 575 subscribers, paying a gross annual rental of £3,920. At the end of March, 1885, there were 918 subscribers, representing a gross annual rental of £6,433. This shows an increase of 343 subscribers, and of £2,513 on the annual rental. There also were 264 persons wishing to join the exchanges, with a gross annual rental of about £2,000. With regard to the Edison-Gower Bell Telephone Company, at the end of March, 1884, the two exchanges of Lisbon and Oporto had 586 subscribers, paying a gross annual rental of £3,821; and at the end of March, 1885, there were 870 subscribers, paying a gross annual rental of £5,380. This shows an increase of 284 subscribers, and of £1,559 rental during the year. As to the River Plate Telephone Company, on the 29th February, 1884, the number of subscribers in the exchanges of Buenos Ayres and Monte Video was 1,571 with a gross annual rental of £27,000, and on the 28th February, 1885, there were 1,858 subscribers, paying a gross annual rental of £29,400. This shows an increase of 287 subscribers and £2,400 gross income. The total increase in the exchanges, as compared with 1884 and 1885, may thus be stated:—

Telephone Company of Austria	343 Subscribers.	£2,513 Rental.
Edison Gower-Bell Telephone Company	284 ,,	1,559 ,,
River Plate Telephone Company	287 ,,	2,400 ,,
Totals	914	6,472

In accordance with the Articles of Association the following Directors retire by rotation, and being eligible, offer themselves for re-election, viz.:—Major Fitz-Gerald, John Taylor, Esq., and Richard Van-Zeller, Esq. The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and A. E. Green, Esq., also retire, and offer themselves for re-election.

NOTES.

NOTICE OF REPAIR.—The cable between Para and Maranham is repaired.

NOTICE OF INTERRUPTION.—The land lines in Guatemala are interrupted.

PROPOSED NEW CABLE.—A telegram from Japan announces that it has been arranged to lay an English telegraph cable to Nagasaki.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 22nd inst. amounted to £3,370.

THE AUSTRALIAN TELEGRAPHS.—A post and telegraph station has been erected in the township of Narridy, in South Australia, at a cost of £1,000.

A NEW LAND LINE.—A special land line of telegraph, built by the Commercial Cable Company, and extending from Havre to Paris, was, says an American contemporary, opened on 24th April.

ENTERPRISE.—The New Montezuma Hotel at Los Vegas, N. M., has been fitted by the United States Company with the Weston incandescent lights. There is not one foot of gas pipe on the premises.

THE BRITISH ASSOCIATION MEETING.—The subject of Prof. W. G. Adams's address at the forthcoming meeting of the British Association will be "The Electric Light and Atmospheric Absorption."

TELEGRAPH STORES.—Particulars will be found, in our advertisement columns, of stores, consisting of telegraph apparatus, wire, &c., for which tenders are invited by the Directors of the North Eastern Railway.

THE ELECTRIC LIGHT AND RAILROAD CROSSINGS.—The Springfield, Ill., City Council has passed an ordinance providing that railroad companies shall erect electric lights at all principal streets crossed by said roads.

PERSONAL.—Mr. C. Todd, C.M.G., the South Australian Postmaster-General and Superintendent of Telegraphs, has announced his intention of leaving Adelaide on leave of absence. He will visit England and Europe, and probably America.

SILICIUM BRONZE WIRES.—The silicium bronze wires of M. Lazare Weiller seem to be giving some degree of satisfaction in Switzerland and in Bavaria, where, in addition to Austria, they are largely employed for telephonic and other purposes.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 22nd May were £2,706, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE JABLOCHKOFF AUTO-ACCUMULATOR. — Despite the glowing accounts which continue to be given of this accumulator, we hold our opinion in reserve. A practical trial of the apparatus may not improbably demonstrate its utter worthlessness.

THE ELECTRIC LIGHT AT EASTBOURNE.—The Eastbourne Electric Light Company have recently fitted up new and more powerful machinery in their works in Junction road, and have also made several important improvements in the working of the electric light.

SYNDICAT PROFESSIONNEL DES INDUSTRIES ELECTRIQUES. At a meeting of this syndicate, held last week, it was decided that the general meeting be postponed until the commencement of June. The syndicate has under consideration certain questions relative to the Antwerp and other exhibitions, &c.

THE LONGITUDE OF TENERIFFE.—It is stated that M. Bouquet, membre de l'Institut, has arrived at Santa Cruz de Teneriffe, to determine, on behalf of the Government, the geographical position of that town with Senegal and Cadiz, the cable communication between those points being utilised for the purpose.

THE SCELLOS BELTING.—The Scellos belting, for electric lighting purposes, continues to receive the support of our contemporaries in France. It is said to be of a superior quality of leather, and composed of different bands not exceeding 1·5 metre in length, which are joined together in such a manner as to give great strength and pliability.

THE ELECTRIC LIGHT IN AMERICA.—Lake City, Minn., will soon have the electric light in operation. The Bridgeport Electric Light Company has offered to renew its various contracts with the city for street lighting. The price of lights is to vary from $1.50 per light per year to $1.75, and to burn from sundown to 3 a.m. every night in the year.

ELECTRIC LIGHT TEST.—On the 6th instant, the 600-hour test of the electric lights at the Exhibition Building, West Philadelphia, was completed. The 1,000-hour test is yet to come off. Only six dynamos are now in the building for testing—three of the Edison, and three of the Weston pattern—but more are expected. The tests will not be finished before the middle of June.

SIXPENNY TELEGRAMS.—By arrangement and for the general convenience of members the second reading of the Sixpenny Telegrams Bill was agreed to without a division. Lord John Manners' amendment in favour of free addresses will be brought forward and pressed on the next stage of the Bill. There is reason to believe that it will receive the support of the majority of the House.—*Standard.*

THERMO-ELECTRIC PHENOMENA.—At a meeting of the Reale Accademia dei Lincei, Rome, Dr. Battelli, after giving a *résumé* of the theoretical explanations offered by Thomson and Tait to account for the results obtained experimentally in thermo-electric phenomena, stated also the hypothesis of Kohlrausch on the electrical transport of heat, and showed how, from the conclusions of Kohlrausch, all the formulæ confirmed by experiment might be deduced.

NATIVE MERCURY.—Native mercury has been discovered on the west bank of the Mississippi, about ten miles above New Orleans. An analysis of two triturated specimens of half-dried earth gave the following results :—

1. Weight of soil,	500 grms.	Wt. Hg,	1·4652 grms.	p.c.	0·0029+
2. ,, ,,	500 ,,	,,	1·4687 ,,		0·0029+
Total,	1 kilo.	Total,	2·9339	,, mean, p.c.	0·002934

Or a mean percentage of mercury of 0·002934 per cent.

TRAIN LIGHTING.—The Great Northern Railway Company are lighting one of their trains with "E.P.S." accumulators placed in each coach. The cells are charged by a dynamo driven from the axles, and an "E.P.S." magnetic switch closes the circuit when the E.M.F. of dynamo rises above that of the cells. The Electrical Power Storage Company have lately supplied accumulators for use on the Lancashire and Yorkshire, as well as the Great Eastern Railways.

PHOTOGRAPHY BY ELECTRIC LIGHT.—At the artists' fancy dress ball, recently held at the Prince's Hall, Piccadilly, a large number of photographs were taken throughout the evening by Mr. Barraud, of Regent-street, by the electric light. The

Digitized by Google

negatives are said to be as good as those taken by daylight. Two arc lamps, with 10 ampere current, were supplied with current from "E.P.S." accumulators. The installation was carried out by the Electrical Power Storage Company.

THE GROSVENOR GALLERY INSTALLATION.—We are informed that the whole of the power for driving the electric light machinery at the Grosvenor Gallery is to be transmitted through the patent friction pulleys and clutches of Messrs. J. Bagshaw and Sons, of Batley, Yorkshire; and in accordance with instructions from Messrs. Marshall, Sons, and Co., Gainsborough, the firm are also manufacturing one large clutch of 300 horse-power, and others of 150 horse-power each.

THE NATIONAL SELF-BINDING INSULATOR.—This insulator possesses certain new features which appear to be of greater practical value than any improvement made in glass insulators since the introduction of the internal screw-thread. The improvement enables the ordinary tie-wire to be wholly dispensed with, the insulator, with its clip, being so formed that the line-wire is readily placed in position, and rigidly secured without the aid of tools. The insulator can be applied in any position, wherever the ordinary pattern is available.

DEATH OF A POST OFFICE OFFICIAL.—The death is announced of Mr. Thomas Boucher, who was appointed to the Post Office in 1834, and subsequently promoted to be Controller of the Circulation Department. In 1875 he was raised to the rank of Surveyor General, which position he held until 1877, when, on account of failing health, he retired from the service. When in 1855 Mr. Rowland Hill commenced the London Postal District System he was ably assisted by Mr. Boucher, to whom the greater part of the arrangements were entrusted.

ELECTRIC SIGNAL BALLOON.—A new departure in military signalling has been made by Mr. Eric S. Bruce, son of the late General Michael Bruce, who commanded the Grenadier Guards. He places an incandescent lamp in the body of a translucent captive balloon, and flashes signals according to the Morse code by making and breaking contact, thus permitting signalling to be carried on at great altitudes and to considerable distances. Mr. Bruce is experimenting with various lamps and batteries, so as to determine those best suited to his purpose, and he will describe the invention at his forthcoming lecture at the Birkbeck Institute on 10th June. Moreover, the balloon is soon to be on view at the Inventions Exhibition, in the War Department, Group 25, near the main entrance.

ELECTRIC LIGHTING IN LUXEMBURG.—The first application of the electric light in the Grand Duchy of Luxemburg was the temporary installation of a Schuckert dynamo and fifteen arc lamps, for the purpose of facilitating the progress of the new Thomas Gilchrist steel works at Dudelange or Dudelingen. It is expected that two blast furnaces will be blown in during June, and the steel works started in October, when there are to be three dynamos, two at work and one in reserve. A novelty in the permanent installation is that the same engine, horizontal, with air-pump and condenser in line with the cylinder, will drive the Kley fans for blowing the pig and spiegel cupolas when required during the day, and the Schuckert dynamos at night. MM. Glaesener Frères have lately completed an installation of incandescent lamps, maintained by their new secondary batteries, in the Luxemburg Prison.

OVERHEAD WIRES AND THE COURT OF COMMON COUNCIL.—At a meeting of the Court of Common Council held recently the Chairman of the City Commission of Sewers was asked if it were true that the Streets Committee and the officers of that Commission were to spend the Whitsun holidays in Paris in order to investigate the system of underground telegraphic and telephonic communications, and if so whether the visit would cost about £800, and whether that sum would come from the City's cash or otherwise. The Chairman of the Commission, who eventually rose in response to loud calls, said the Commission had been considering, in the interests of the public, the dangers and inconveniences arising from the present system of overhead telegraphic and telephonic wires, and they were called upon to give evidence on the subject before a Select Committee of the House of Commons. They had commissioned a certain small deputation of their number to visit Paris to examine the successful system of underground telegraphic and telephonic communication. Their visit, which would be paid, like their other expenses, from the rates, would cost less than their obtaining the information through experts, and as the results would be to the public advantage, the money would be well spent. As for going in the Whitsun holidays, that was the only time at which the deputation, who were all business men, could go.

WHIT MONDAY AT THE INVENTORIES.—In an article entitled "A Monster Day at the Inventions," the *Daily News* says:—"In due time the conservatory and main buildings were suddenly outlined with what seemed to be small copper nails, and when the nails grew as by magic into bright lamp lights a roar of surprise and admiration drowned the music of the bands. This marvellous electrical illumination is not literally effected instantaneously. The installation throughout the grounds consists of twenty-three circuits, made into eight sections, and to each section there is a switch controlled by Sir Francis Bolton or his assistant in the clock tower. First, therefore, to appear were the glow lamps at the upper end; then in quick succession followed those of the main buildings, trees, and flower beds. The general effect was enthusiastically recognised. The illuminations are, as we learn, however, still in the experimental stage. These 20,000 glow lamps almost simultaneously starting into light are a marvel of electrical progress; but as they never twinkle, and are necessarily arranged with regularity of line and pattern, they have somewhat, as a general design, the prim formality of an Italian garden. Coloured lanterns suspended from the branches would supply the small effect that is wanting for perfection. Last night, however, the lamps and the lovely fountains as they were proved all-sufficient in affording pleasure. It was, under all the circumstances, a grand day at the Inventions."

RADIATION V. ELECTROLYSIS.—Mr. Frank Lockwood recently had occasion to examine a lamp which has been in use a long time in the premises of a large silver-ware manufacturing firm in this city. It is an ordinary 16-candle Edison lamp, and at present has almost the appearance of a solid globe of bronze, so great is the deposit of copper within it. The explanation is apparent; electrolysis of the copper has resulted in the fourth condition of matter, and not as ordinarily in cases of this kind, in the third or gaseous state. The peculiar effect is due in part to radiation and not simply to decomposition. This is demonstrated by the directions taken by the matter, and by the fact that the distribution has taken place from one point, which, so far as can be judged, is one of the copper clamps holding the filament of carbon. It is also verified by the fact that from the top of the lamp to where the other clamp is situated a thin line of clear glass may be observed, following the line of the carbon filament and evidently protected by it from the deposit of particles proceeding from the centre of

Digitized by Google

radiation. It is a somewhat novel phenomenon, and we think on that account deserves notice. Aside from the elaborate experiments of certain physicists, the often peculiar and sometimes startling effects of the fourth condition of matter have perhaps not received the attention they are justly entitled to. The study of these phenomena is at once entertaining and instructive, and undoubtedly will in time become more general than it is at present.—*American Electrician.*

THE TELEGRAPHS IN THE FAR EAST.—No action has yet been taken by the Government in the direction of constructing an independent cable to Singapore, and delay is much deprecated in Hong Kong. The Hong Kong correspondent of *The Times* says:—"Three things are well known to be needed immediately in the Far East, and these are not mere *pis-allers*, but permanently required when the fortifications, &c., are completed—namely, (*a*) a sufficient number of torpedo boats, properly manned and equipped, for all the principal harbours and coaling stations; (*b*) telegraphic communication, by a direct English cable, from Hong Kong to Singapore; and (*c*) a reinforcement of the garrisons, especially at places like Singapore and Hong Kong. The importance of direct telegraphic communication so as not to pass through hostile or possibly hostile territory, so invaluable at the outbreak of any war, need not be urged here. To a nation like ourselves, with the enormous interests involved, one would imagine that we should recognise the absolute necessity of being forearmed by being forewarned, and this at any cost. Far from costing an enormous sum, however, this might have been accomplished by a small guarantee contributed by the Imperial Government, Hong Kong, and Singapore, and, if commenced when the scare begun, have been now working. Nothing whatever has been done in this matter; it has not even entered upon the chrysalis stage. The official answer to our demands is easy enough to predict. Put, of course, in a very much more plausible form, the responsible officials will tell us:—'If the colonies and Indian ports want torpedo boats or English cables they must pay for them themselves.' A terrible blunder will be committed if this attitude be persisted in."

RESEARCHES ON THE ACTION OF THE COPPER-ZINC COUPLE ON ORGANIC BODIES.—Dr. J. H. Gladstone, F.R.S., and Mr. Alfred Tribe have extended their previous researches on the action of the copper-zinc couple on organic bodies to compounds of the aromatic series. Ortho and para bromotoluene are not attacked by the couple, but the isomeric benzyl bromide, C_7H_7Br, is very readily acted upon. So rapid, indeed, is the action that it is necessary to operate with only very small quantities at a time. Some bromide of zinc is formed, but the main products are bromhydric acid and two apparently different resin-like bodies, the one soluble and the other insoluble in ether, which become viscid at a little above the ordinary temperature, and are decomposed on distillation. Though no specimen was obtained pure, combustions indicated that they were hydro-carbons of the empirical composition C_7H_6, and this was supported by evidence derived from their specific refraction and dispersion. It is proposed to name them α and β benzylene. The bromo and nitro-compounds are uncrystallisable bodies. *In the presence of ether* the reaction is very different. The zinc is dissolved in a larger proportion than would be necessary to form $ZnBr_2$; in fact, the proportion of zinc to bromine is very constantly 1:1·6. The organic zinc compound was not isolated, but it is decomposed by water with the formation of zinc hydroxide, zinc bromide and toluene. When the compound is strongly heated, dibenzyl also separates from it. *In the presence of absolute alchohol* the reaction takes another form. Toluene, C_7H_8 is produced, and a bromo-zinc organic compound, doubtless bromoethylate of zinc, $ZnBr.OC_2H_5$. Some dibenzyl was also formed. *In the presence of water* the action was slow at the ordinary temperature. The benzyl bromide was found to be mainly resolved into dibenzyl and zinc bromide, but some toluene and zinc oxybromide were also produced. One or two other compounds formed in smaller quantities were partially examined, but the investigation was not carried further on account of the extremely noxious character of the vapour of the original substance.

MEASUREMENT OF STRONG ELECTRIC CURRENTS.—In a letter to Silliman's *American Journal*, Mr. J. Trowbridge says:—"I have no reason to change my belief, that a dynamometer is the most suitable instrument for measuring strong currents. I have lately, however, employed the cosine galvanometer for this purpose in the following manner:—The galvanometer is mounted so that its compass is at the centre of a large circle of wire, the plane of which is vertical and is in the magnetic meridian or in the plane of the needle of the compass, whatever that is. When the current from a dynamo machine is passed through the large vertical coil, which may consist of a single wire, the arrangement answers as a tangent galvanometer. I then connect the movable coil of the cosine galvanometer with a Daniell cell of known electromotive force, place in the same circuit a resistance so large that the battery resistance can be neglected, and having joined the poles in such a manner that the deflection produced by the coil of the cosine galvanometer shall be opposite to that produced by the current from the dynamo machine in the large outer coil, I incline the coil of the cosine galvanometer until the compass-needle is brought again to zero. We then have, if we represent by F and F′ the force produced at the centre of the coils by the current from the dynamo machine and by the Daniell cell, S and S′ the respective currents, r and r' the radii, n and n' the number of coils in the two galvanometers, and H the horizontal force of magnetism:—

$$F = \frac{2\pi n S H}{r} = P' = \frac{2\pi n' S' H}{r} \cos\alpha, \quad \text{or } S = \frac{S' n' r}{n r'} \cos\alpha.$$

The strength of the current from the dynamo is thus simply obtained in terms of the current from the standard Daniell cell, and the method is independent of the strength of the earth's magnetism, or of the special field in which the instruments may be placed. The diameter of the outer coil can be diminished by employing Prof. Brackett's method of passing the current through one coil in one direction, and through an inside coil in another. In an experimental trial I employed simply a scaffolding of wood, upon which a single turn of wire was fixed as a vertical circle.

TELEGRAPH CONSTRUCTION IN CHINA.—Our Hong Kong contemporary, the *China Mail*, says:—"In November last we referred to the telegraphic communication to be established between the port of Pakhoi and a point in Kwangsi (Wang Chow) on the main line from Canton to Lung Chow (on the Tonquin frontier), which passes Nanning. This line was completed on the 4th of February; the first message went through at 4 p.m. on that date, and it was notified that the Chinese Telegraph Company's lines had been placed at the disposal of the public generally free of charge *for all messages handed in at Pakhoi* for the term of three days ending on the evening of the 6th of the month mentioned. We understand that the telegram received by us was the first private message forwarded. The building of this line, which passes by Lingshan and Liemchow, has been a hard task, and those engaged in it have had to endure much suffering from the inclement weather and severe cold experienced throughout. The work was calculated

Digitized by Google

to take three months, but it has been completed some ten days ahead of that time. Taking into consideration the facts that one month was lost in waiting at Wang Chow for poles and wire (which should have been there in October), that the country traversed was mountainous and imperfectly surveyed, great credit is due to the energetic Danish gentleman, Mr. Mühlensteth, of the Great Northern Telegraph Company, by whose skill and experience the work has been accomplished. In recognition of the great exertions he has made to complete the Wang-Chow-Pakhoi line under extremely adverse circumstances, his valuable services have at once been secured by the Chinese Government for the building of a new line from Liemchow westward towards the Anamite frontier, passing by Chin-chow and Yam-chow. He set out on this new work on the 7th inst., and the line is expected to be completed in about six weeks. Two other Danish gentlemen, Messrs. Jensen and Madsen, belonging to the Chinese Telegraph Company, have also just started for Liemchow to proceed with the building of a telegraph line from that place to Hainan (surveyed by Mr. Jensen a couple of months ago), which is to connect this port with Kiung-chow. The cable from Hoihow to Cape Cami was laid in November last. This line will also be completed in about six weeks, material not failing. The only station between this and Wang-chow is at Liemchow, whence lines will thus go out in four directions."

THE ELECTRIC LIGHT IN CHICAGO.—Our American namesake says:—The United States people have lately put an extensive plant in the Post Office portion of the Government buildings in Chicago; and, by the way, despite the defeat of the Republican party in November, these seem to burn just the same under a Democratic administration. The same company are wiring large plants in the Home, the North Western, and the Royal Insurance buildings, the Mahler building, and the barber shops of the Palmer House. In these several plants there is a total of about 4,270 glow lamps. The Edison people, too, are full of work, wiring the new Board of Trade building, adding to the Pullman building plant, and the county buildings at Wauwatosa, near Milwaukee, and will soon be wiring the city buildings and the two tunnels from the south division to the west and north divisions of the city. This latter plant will consist of two engines and four generators, which will be placed in the basement of the city buildings, with a capacity for 1,500 lamps of 16 candle-power. Of these about 300 will be distributed between the tunnels, the remainder in the corridors and various offices of the city building. It is proposed to light only a portion—about one-third—of the tunnel lamps during daylight, the entire number being in use at night, while an average of three hours per diem will be the use of those in the building. Advertisements for bids were published early in the past winter, and the Edison Company made proposals for furnishing the plant in accordance with the above data, for 41,375 dols., and the Council at the regular meeting of the 30th of March, ordered: "That the controller is hereby directed to enter into a contract with the Western Edison Company, in accordance with the proposition of the said company, dated 26th December, 1884, in regard to lighting the buildings of the city, for the sum of 41,375 dols." The city officials, whose duties require artificial light to a greater or less extent, are as tickled as a boy with a new top at the approaching release from the thraldom of gas. As one of these remarked to the writer, "This light is like fresh eggs compared to the kind that are only fit for scrambling, when placed alongside of gas. A gas plant is a bad egg all the year round—a bad colour, pollutes the air, and—smells." Then again M'Vicker's Theatre is to be lighted with incandescent lights. So is the new Chicago Opera House; and the present Grand Opera House has lately blazed up with glow lights. This last is a Mather-dynamo-Perkins-lamp plant, and makes a very pretty show indeed. A stage trick accompanied its inauguration. On the night of its *début* the auditorium was lighted up as usual with gas jets. All being ready these were extinguished, and electric lights substituted. The audience, at first astonished and bewildered, then pleased, saw the joke, and broke into the most uproarious applause, indicative of their approbation.

BOOKS RECEIVED.—"On the Mechanical Characteristics of Lightning Strokes," by Col. the Hon. Arthur Parnell. The main objects of this essay, which is a reprint from the *Quarterly Journal* of the Royal Meteorological Society, are as follow: First, to show that lightning is not a sort of electric fluid that descends from the clouds, injures buildings and persons in its course, and dissipates itself in the earth, but that it is a luminous manifestation of the explosion caused by two equal forces springing towards each other simultaneously from the earth and the under surface of the inducing cloud, and coalescing or dying out nearly midway between the two plates of the electrical condenser formed by the earth and cloud; secondly, to demonstrate that of these two forces it is the earth-sprung or upward force alone which injures buildings, persons, or other objects on the earth's surface, and which constitutes tangibly what is known as a lightning stroke. Some of our readers, we are afraid, will find this hypothesis rather difficult of explanation, unless they accept the author's statement that in 1759 the English philosopher Symmer revived and remodelled Dufay's ideas into the "two fluid" theory that has since been *universally accepted as the correct one.* The italics are our own.—"Facts Proving that Lightning is a Composite Force," by Mr. Wm. Boggett, is a publication upon somewhat similar lines. Mr. Boggett's ideas on the subject of electricity, like those of other people whose knowledge of science is superficial, are peculiar. He says: "In the hope of removing all doubts from the minds of electricians as to my conception that lightning is a composite force, I append the following facts." We repeat *facts*:—"(1) Electric force in an active state always comprises two currents. (2) The said two currents invariably move in opposite directions, owing to one being positive and the other negative. (3) Each of the two currents has electricity as its basis, &c." It is kind of Mr. Boggett to remove our doubts in this fashion. We are entirely with him in his belief that "lightning results from electric action," and that "thunderstorms frequently happen on the ocean," and if we ask with him whether "the most gifted electrician can explain from what other source than water electricity is derived," it is only in the hope that a few facts on the subject will eventually reach a quarter where they are obviously required.—"A German Grammar and Reader for the Use of Science Students," by Emil Beyer, lecturer on German at the Technical College, Finsbury, E.C. (David Nutt, 270, Strand), is a useful little work, containing besides the grammar proper a compendious vocabulary of words relating to the mechanical, chemical, and electrical sciences. It will facilitate in a very great measure the study of treatises of a technical nature, and we must, therefore, congratulate the author upon the apparent thoroughness of his labours.

ELECTROLYSIS OF DILUTE SULPHURIC ACID.—An abstract of a paper by M. F. Richarz, in the last issue of the Society of Telegraph Engineers' *Proceedings*, says:—"In his experiments the author at first made use of a U tube, but this had to be abandoned, as the results were not concordant, owing to the concentration of the sulphuric acid in the leg of the tube containing the positive electrode. A straight tube was then

Digitized by Google

used, which was clamped in a vertical position. The positive electrode was formed by a platinum wire placed in the upper part of the tube, the two ends of the wire being sealed into the glass at two points vertically below each other. The object of having both ends brought out of the tube was in order to enable the wire to be brought to a red heat by the passage of an electric current, it having been found that, unless this were done previously to each experiment, the results did not agree. The negative electrode finally decided upon, after a trial of thin plates of platinum, was a similar platinum wire fused into the opposite side of the tube, and lower down than the positive one. The whole apparatus was kept at zero temperature by being surrounded with melting ice; and the current used for effecting the electrolysis was kept constant by observing the deflections of a tangent galvanometer, and putting in or cutting out portions of a resistance which formed part of the circuit. The galvanometer constant having been accurately determined, it was also possible to calculate the total amount of gases which should have been liberated by the passage of the current, and thus to check the quantities determined by the chemical analysis. The quantity of ozone formed was determined by the amount of iodine set free from a solution of potassium iodide, this amount of iodine being estimated by its reaction on normal sodium sulphite. The sulphur trioxide formed was calculated from its action on ferrous sulphate, which it converts into ferric sulphate. For the determination of the hydrogen dioxide, the permanganate of potash test was used. At first the positive platinum wire electrode was not heated, and it was then found that the results did not agree. The author sought for the cause of this, in the first instance, in the negative electrode, but he found that this did not affect the result, nor did the evolution of hydrogen, nor impurities such as lead or manganese in the electrolyte, and he therefore concludes that this alteration of the positive electrode was due to the evolution of oxygen. The reduction of the sulphur trioxide at the negative electrode causes a disappearance of a quantity of hydrogen equivalent to its own oxygen, which will be shown by a deficiency in the total quantity of gases produced. It was clearly proved that the sulphur trioxide was reduced by the nascent hydrogen; also that the formation of these higher oxides is dependent on the temperature, and that the quantity of sulphur trioxide decreases much more quickly with rise of temperature than the ozone. The author also found that the quantity of these evolved gases increased with the current density, and that he consequently got better results when using wires than when using plates. The degree of dilution of the sulphuric acid also has its influence on the amount of gas evolved, and it was found that the largest quantity of sulphur trioxide was formed when the electrolyte contained from thirty to forty per cent. of sulphuric acid. It was more difficult to determine the quantity of ozone, but it seemed at any rate that with a solution containing more than sixty per cent. of acid the quantity was less than with more dilute solutions."

THE PHYSICAL SOCIETY OF BERLIN.—At a meeting of this society, held on the 6th March, Dr. Kalischer described a new secondary battery intended to overcome the disadvantage of the usual accumulators, namely, that the sheet of lead used as anode got very soon destroyed. This object he attained by adopting a very concentrated solution of nitrate of lead as electrolyte, and iron as anode. The iron, on being immersed in the solution of lead, became passive and resisted every corroding effect of the fluid; in other respects the peroxide of lead on the electric charge became deposited at the anode as a very firm coherent mass enveloping and protecting the iron on all sides. The charge was continued till the greater part of the nitrate of lead was decomposed, a condition which was marked by the occurrence of a greater development of gas at the anode. At the beginning of the charge all development of gas must be avoided, as otherwise the peroxide of lead, or, more correctly, the hydrate of peroxide of lead, became covered with bubbles. As cathode a sheet of lead was used, but it was attended by two disadvantages. In the first place the lead, during the charge, separated itself at the cathode into long crystal threads, which soon passed through the fluid, and produced short closing (of the current). In the second place the nitric acid, which remained in the fluid after the separation of the lead, acted very powerfully on the sheet of lead. Both disadvantages Dr. Kalischer avoided by amalgamating the cathode. This accumulator of iron, concentrated solution of nitrate of lead, and amalgamised lead yielded, after the electric charge, which could be carried out without any special preparations, a current of about two volts. After about six hours' discharge, however, the electromotive force sank to 1·7 volt, but, on the battery being left to itself for twenty-four hours, it became a little increased. According to the measurements hitherto taken, the functions of this accumulator were satisfactory. An attempt to substitute sulphuric manganese for nitric lead in this battery did not answer the purpose, as the peroxide of manganese separated itself, not in a continuous layer, but in loose scales. At another meeting of the same society, on the 20th March, Dr. Gross, starting from theoretical considerations, instituted the following experiment:—Two iron electrodes, overlaid with sealing wax in such a manner as to leave only the terminal planes free, were dipped into a solution of chloride of iron, closed by means of a galvanometer into a circle, and any inequalities there might happen to be adjusted according to the Poggendorf-Du Bois-Raymond method. When now one electrode was surrounded by a magnetising spiral, there was seen, on its being magnetised, an electric current passing from the magnetic electrode through the fluid to the non-magnetic electrode. It might be thought that the current was a thermo-electric one, produced by the warming of the magnetising spiral; but a delicate thermometer showed that the air within the magnetising spiral was but 2° warmer than the surrounding air. Besides, the electrode that was to be magnetised was surrounded by a double cylinder, through which water of a temperature 12° below that of the air was constantly flowing; and yet, notwithstanding this powerfully cooling influence, the current always passed from the magnetic to the non-magnetic electrode, whereas a thermal current must have passed from the warm to the cold electrode. The electric current was therefore produced, not by a difference in temperature, but by the magnetisation of the one electrode. The current continued so long as the electrode was magnetised. If the electrodes were now brought into a tube, and so arranged as to lie behind each other in the axis of the tube, with their free terminal planes turned to each other, then, on the magnetisation of one electrode, an electric current again set in, passing now, however, from the non-magnetic electrode, through the fluid, to the magnetic electrode. The direction of the current was consequently dependent on the direction of the magnetic axis to the electrolyte and the second electrode. As conducting fluid only sulphates of iron could be used in these experiments, and of these only such as received the free terminal plane of the electrodes nakedly. Dr. Gross believed that the currents demonstrated by him in the experiments thus described were related to the thermo-electric currents between magnetic and non-magnetic iron wires, which were a subject of study to Sir William Thomson.

THE CHARGING OF SECONDARY BATTERIES.*

BY WILLIAM HENRY PREECE, F.R.S.

1. I have for the past twelve months been experimenting with secondary batteries, with a view of getting an efficient, uniform, and constant source of currents for electric lighting my house, and I have succeeded beyond my expectations. Some new facts have developed themselves during my experience, which I have thought of sufficient importance to bring before the society.

2. The cells are of the Planté type, manufactured by the Elwell Parker Company, of Wolverhampton. Fourteen plates of plain sheet lead, 17in. × 11in. are suspended in well insulated wood boxes filled with diluted sulphuric acid in the proportion of about 1 to 10. These plates are grouped in two groups of seven, each group being soldered to a lead strip, forming alternately the positive and negative poles of the cell. The plates of the respective poles are prevented from touching each other by ebonite grids or separators†. Each plate offers a surface of 1·3 square foot, so that the total surface of lead of each group opposed to each other is 9·1 square feet; that is, 9·1 square feet of peroxidised lead is opposed to 9·1 square feet of spongy lead. I use 24 such cells.

3. My charging current varies from 3 to 3½ amperes per square foot, while the current discharge used in lighting my house varies from 1 to 1½ ampere per square foot. The total weight of each cell is 120lb. The plates are prepared by the Parker-Planté process before insertion in the cell, those forming the positive pole being well peroxidised, while those forming the negative pole are well coated with spongy lead.‡ They are thus, when put together, prepared at once to be charged. If they are not at once charged, local action sets in, and lead sulphate is injuriously formed.

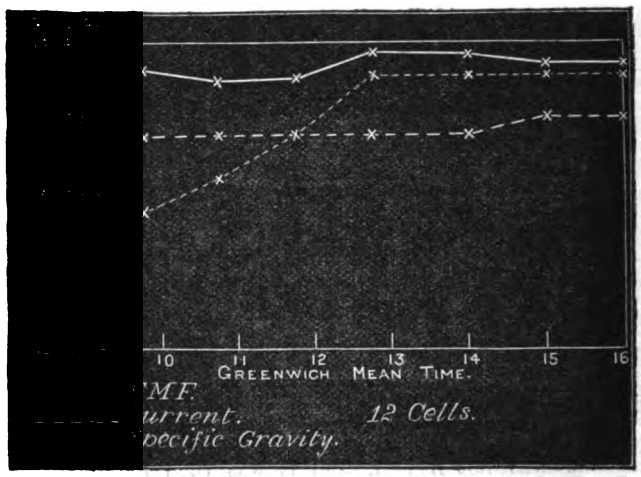
4. I have cut away a small portion of the centre of the central plate of each cell to admit a hydrometer having a scale graduated from 1·050 to 1·150. The changes of the density of the liquid and of the colour of the plates give the fullest and clearest indications of the behaviour of the cell. The condition of the surface of the peroxidised plate as felt by the finger is also good evidence of its condition. If a plate is yellowish-brown and rough, it probably makes bad contact with the lead terminal; if black and hard, it wants the density of current regulated; if plumb-coloured and greasy to the touch, it is in good order, and working well.

5. At the present time I am charging my battery twice a week, putting in at each charge about 120 ampere-hours; the battery is charged in two sections. During each charge observations are made every hour, and sometimes every half-hour (1) of the strength of current flowing through; (2) of the electromotive force; and (3) of the density of one or more of the cells. The relation of these three quantities tells me the condition of the charge. The diagrams (Nos. 1, 2, 3, 4) are typical cases.

Take No. 4, which is the diagram of this morning's (April 28) charge of 15 cells. The following are the particulars:—

	E.	C.	D.
9:0 a.m.	37·7	32·24	1.115
10:0 „	40·2	32·24	1·119
11:0 „	42·5	31·50	1·121
12:0 noon	42·5	30·74	1·123
1:0 p.m.	42·5	29·95	1·124
2:0 „	42·5	29·95	1·124

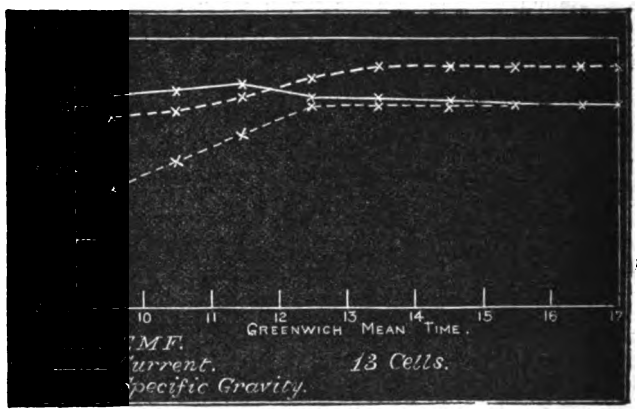
6. It is evident that after four hours' continuous charging the battery was full, for the density, the electromotive force, and the strength of current became constant. The same scale of ordinates is used for volts and amperes. When each magnitude reaches its constant bubbles of gas are freely given forth, and energy is being wasted. The variation of the electromotive force and current strength is clearly due to the counter-electromotive force of the cells, which becomes a maximum only when the plates are fully formed. The counter-electromotive force partakes of the character of a higher resistance opposing the charging current, and increasing the proportion of the current through the shunt of the dynamo. Hence the changes of electromotive force are more marked than those of the current. Indeed, the changes in the electromotive force, as given by the voltmeter, are sufficient alone to



No. 1.

indicate the progress and completion of the charge. They are more reliable than the evolution of gas. (My dynamo is shunt-wound; my voltmeter is Cardew's, a most reliable, simple, and valuable instrument; and my current meter a Siemens electro-dynamometer.)

7. I was at first much troubled with electrical leakage. The current escaped over the edges of the box through creeping, and the formation of moisture from the spray of the solution when bubbles of gas arose in the liquid and burst on the surface. This was quite cured by standing each box on three white porcelain supports of the form shown in the accompanying Fig. A, the cups being half filled with resin oil on Messrs. Johnson and Phillips' plan. It is now quite impossible to measure the leakage except with a delicate galvanometer, and the insulation may be said to be practically perfect.



No. 2.

8. The E.M.F. of the battery at its terminals:—

When charging	2·25 per cell.
When idle	2·05 „
When discharging	1·90 „

* Paper read before the Royal Society.

† These ebonite grids were introduced by Mr. Charles Moseley, and have effectually removed one incessant source of trouble in these cells, viz., short-circuiting through the buckling of the plates.

‡ The Parker-Planté process consists in immersing for a few hours the lead plates in a solution of nitric and sulphuric acids in these proportions:—Nitric acid 1, sulphuric acid 2, water 17, before fixing in the cells. This not only chemically cleans the lead surfaces, but it favours the formation of sulphate of lead in such a way as to be readily converted into lead peroxide and spongy lead on the passage of a strong current through the cells. The formation of the cells is thus greatly expedited.

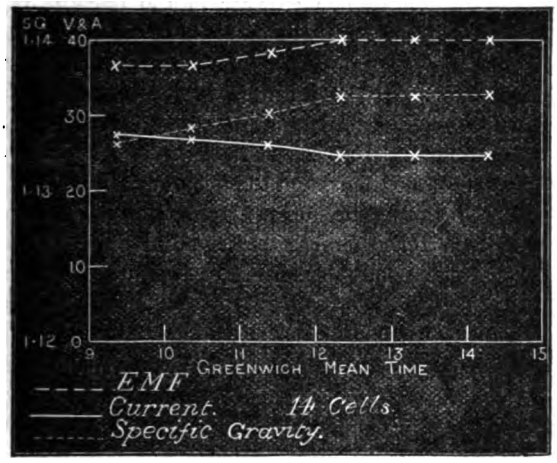
Digitized by Google

The internal resistance is, per cell :—

When charging..... ·0060ω
When discharging ..... ·0017ω

9. But the latter varies very markedly with the strength of current of discharge. This is shown by the following experiment made with 23 cells of a smaller type than those described above, which are used in the Post Office.

Current of discharge in amperes.	Internal resistance in ohms.
4·39	0·7608
7·25	0·4607
15·84	0·2816
25·07	0·1969

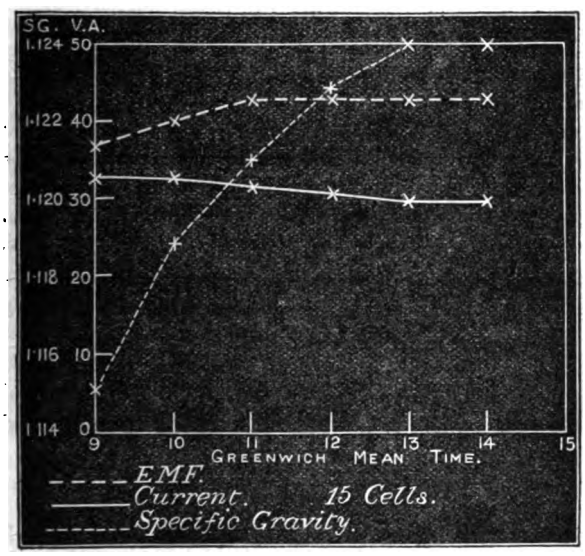


No. 3.

10. Thinking that the remarkable diminution of internal resistance might be due to the evolution of heat, I measured the temperature with a delicate thermometer.

Normal temperature of cell 12½° C. Current of discharge :—

5 amperes ..... No alteration of temperature perceived.
10 „ ..... An exceedingly slight change.
16 „ ..... About 12⅝°.
20 „ ..... Barely 13°.



No. 4.

The current in each case was kept on for twenty minutes, hence the diminution is not due to heat. Since the internal resistance varies in this way, I now always take the internal resistance with the same current, viz., 10 amperes.

11. The capacity of these batteries certainly improves with age, and up to the present time I have seen no sign of decay or deterioration. M. Planté informed me that, though in course of time the peroxidised plate becomes very brittle, it is impossible to peroxidise it completely through; there always remains a metallic core to give it strength. I find that this is so. Up to the present moment I have made no careful measurements of the efficiency of my battery. I cannot do so without deranging the lighting of my house, and I regard observations on single cells as illusory. I put in about 240, and I take out about 200 ampere hours weekly, and I do not observe any change or fall in the electromotive force. When the electromotive force of these cells falls, it falls rapidly, indeed, almost suddenly. Occasionally one plate of a group becomes inactive from undue local action, or from bad connection (shown by the colour). I remove this cell and put it in what I call a "hospital" cell, where it is brought into order either by a greater density of current or by reversal.

12. Reversing has a great beneficial action on a cell ; it not only improves its capacity, but it removes any cause of irregular working. It is advisable to do this periodically. I have two extra cells, which enables me to have two cells always under reversal by means of the charging current. It takes from 1,000 to 1,200 ampere hours to reverse a cell, so that at this time of year it takes a month or more to complete the operation, and it will take a year to reverse the whole battery. I have thus up to the present time reversed 16 cells.

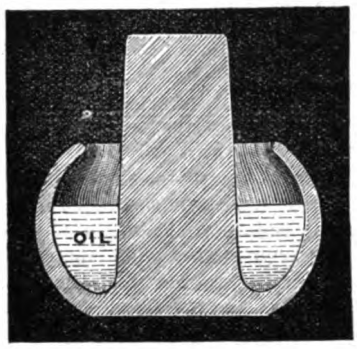


Fig. A.

THE ELECTRIC LIGHT IN LONDON.—From the report of the Metropolitan Board of Works, which has just been issued, we extract the following:—"The lighting by electricity of the streets of London has not apparently made much progress during the last year or two, notwithstanding the numerous provisional orders granted by the Board of Trade under the provisions of the Electric Lighting Act of 1882, and confirmed by Parliament. In some places, indeed, there has been a temporary retrogression, which, however, it may be hoped is only temporary. The Victoria Embankment, for instance, and Waterloo Bridge, which for about five years were lighted by electricity under an arrangement made by the Board, originally with a French company but afterwards with the Jablochkoff Electric Light and Power Company, are now again for a time dependent for their light upon gas. The agreement with the company came to an end on 30th June, 1884, and, as the Board had had several times to complain of the sudden extinction of many of the lights during the hours when they ought to have been constantly shining, and as moreover the affairs of the company were then in liquidation, the Board was unable to renew the agreement. The Board by advertisement in the newspapers invited tenders from parties willing to undertake what had hitherto been entrusted to the Jablochkoff Company, and a small number of tenders were received. None of them, however, offered terms which the Board considered satisfactory. It was therefore decided to revert to gaslight for a time, and to make further inquiries with reference to the most suitable and economical method of lighting by electricity."

THE DEBATE ON SIXPENNY TELEGRAMS.

The second reading of the Telegraph Acts Amendment Bill was allowed to pass last Friday without opposition, on the understanding that if anyone of its opponents could devise a measure securing the same benefits without inflicting a greater loss on the revenue, the Postmaster-General would reconsider the Bill in Committee after the Whitsuntide holidays. If this assurance is to be taken literally for nothing more than it promises, and if Mr. Shaw-Lefevre stands to his pledge to pass the measure on these conditions and no other, then we may safely say that in the month of August next the experiment of a sixpenny telegraph rate on the Continental model will be begun. For it is perfectly evident that no alternative scheme yet suggested, or possible, will meet the conditions imposed. But if the offer which disarmed opposition to the second reading of the Bill betrayed any misgiving as to the soundness of the case on which the Government proposal rests, there will be no lack of critics in Committee who will do their utmost to invite or extort concessions of a kind which from a financial and business point of view would render the experiment disastrous.

Both in Parliament and in the Press there are signs of opposition to the Bill, not perhaps sufficiently strong to upset it, but just sufficient to make its fate uncertain on a critical division if the Government is not thoroughly satisfied that the essential feature of the scheme must be maintained. This essential feature we hold to be, not the maximum number of words for which the charge of sixpence is to be made—though the maximum is sufficiently liberal—but the abolition of the free addresses. It is against this provision, of course, that all the opposition is directed; not because the commercial community objects—quite the contrary, for commercial men see perfectly well that they will be large gainers by the change—but because it is supposed to inflict some hardship on the general public, and the poorer classes in particular. The pretence of objecting to the curtailment of addresses in the interests of the Telegraph Department can be dismissed as of no account; the Department may be presumed to know their own business, and we have their assurance that they apprehend no difficulty in respect to the delivery of telegrams when brevity in the addresses becomes the rule instead of, as now, the exception. Similarly, we may dismiss the prediction ventured by one speaker in the debate, that the new system will discourage the sending of telegrams, and may result in a diminution of their number. He arrived at this, apparently, by having discovered that under the new tariff a long telegram may, and indeed often will, cost more than under the old. Just so; the essence of this reform is to discourage long telegrams, and to encourage short ones. The boon will be in the permission to send a telegram for sixpence, whereas now a telegram can be sent only at the cost of a shilling; and this boon is so large and so valuable in itself that the contingent extra charge for telegrams of exceptional proportions may be disregarded altogether.

On this point Mr. Lefevre's statement has not had justice done to it. His critics all dwell exclusively upon the acknowledged waste of words in the addresses, whereas he pointed out that the same extravagance commonly prevails in the message itself. It is, in fact, notorious that in a large proportion of telegrams the permissible maximum, not the possible maximum, is before our eyes, and we carelessly avail ourselves of the wasteful privilege. One London newspaper eloquently declares that the public demand that they shall enjoy telegraphy at least as cheaply as it is to be had in other countries. The fact is that this is precisely what we are to enjoy next August if we may. In all other countries the addresses, we believe, have never been transmitted free, but have formed part of the message as a whole. It is this fact that has enabled Continental telegraph administrations to be beforehand with us in cheapening their rates, the free addresses in this country causing the prime cost of transmission to be exceptionally high. The maximum of twenty words for the text was too high to begin with, and the addresses being unlimited made matters worse; so that the English telegraph system, ever since the rate was reduced to a uniform shilling, has never had a fair chance of being remunerative; and to reduce the charge on the same footing, or anything like the same footing now, would be simply ruinous. If the existing system were a real privilege, something might be said for its retention even at a financial sacrifice; but all authorities in this country are agreed, and the experience of Continental administrations bears them out, that a comparatively low maximum will occasion no inconvenience, and that a higher one is downright waste. There is a wide difference between a tariff of twelve words and one with an average of twenty-seven. But so there is between six pennies and twelve; and when it is known that the general run of messages, with their addresses, might be reduced by half, or nearly half, without any hardship at all, the balance of advantage to the public in being able to send a short message for the smaller sum must be held to outweigh the trouble of cutting down superfluous verbiage in the message, and elaborated courtesies in the addresses.

As to the alleged hardship to the working classes who have long addresses, their short messages will make amends for that.

Digitized by Google

The picture of the working man being "deterred" from sending a telegram for sixpence now that the addresses are to be charged for is something too ridiculous even for a sentimental Parliament to weep over. We don't much believe in this new patron of the telegraphs; but supposing he turns up, he will find his advantage, like other people, in being able to send a message for half what it would cost him now if he chooses to cut it short. Mr. Shaw-Lefevre has wisely helped him in this matter by adopting the Continental practice of allowing five figures to count as one word, and compound words in the addresses to be treated in a similarly liberal spirit. These concessions, especially the one relating to figures, have been too little noticed. They will in effect expand the maximum by at least one or two words in almost every case; and in commercial messages, where figures are of frequent occurrence, the advantage will be even greater. If the critics of the Bill are not satisfied with this, the responsibility of losing it altogether should be thrown upon them. Those who complain of the anomalous effect on long telegrams under the proposed tariff should be reminded that a far greater anomaly prevails in respect to short telegrams under the existing tariff. One person may send forty words for no more than a shilling, whilst another person has to pay half as much again, or more, for fewer than thirty if the excess happens to be in the message and not in the addresses. This is not merely an anomaly; it is an injustice—to the department in the one instance, to the public in the other; and it can only be remedied by taxing the despatch as a whole.

CORRESPONDENCE.

NEW ELECTRICAL EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: While experimenting with vacuum tubes on the 23rd inst. I observed a phenomenon which I have seen no published account of. The source of electricity used was a coil machine, the primary coil being excited by a battery. Having by the means of a small insulated gas flame determined the direction in which the current of electricity was passing between the terminals of the secondary coil, I applied the plus or electricity-giving terminal of the coil to the right arm of a V-shaped vacuum tube, and the minus or exit-terminal of the current I attached to the left-hand terminal of the V tube. As seen in the dark the right hand arm of the tube was full of pink coloured rays of light extending from the platinum terminal at the top of the arm down to nearly the bottom, but not to the very bottom of that half of the tube; the pink rays of light stopped at a horizontal line parallel with the upper edge of the bent part of the tube. The left arm of the tube was filled with a greenish-yellow light, which extended round the turn at the bottom of the tube until it met the horizontal line of pink light in the right arm of the tube. The greenish-yellow light filled all the left arm of the tube, except a small inverted pyramid of pink light which was attached to the under side of the platinum disc, which forms the inner end of the terminal of the tube. This small inverted pyramid of pink light was evidently kept in existence by particles of the pink light coming from the right arm of the tube, but these particles of pink light were invisible as they passed up through the greenish-yellow light in the left arm of the tube. It was only on their arriving close to the platinum disc that they became visible as they rushed against it. This state of matters led me to think that a change would take place if I inverted the tube, and used it like a letter Λ instead of a V. Having inverted the tube, I passed the electricity through it in the same direction as before. The right arm of the tube was again filled with rays of pink light, which now turned the corner of the tube and descended into the left arm, filling it also with the pink light. From this it was manifest that either the magnetism of the earth or the attraction of gravitation had been the cause why the pink light did not freely ascend into the left arm of the tube when it was used like a letter V. To determine this question I made the following experiment with a straight vacuum tube, 13½in. in length between the inside terminals and ¾ of an inch in diameter, and having at one end of it a small chamber for holding potash, so that when the latter is heated the vacuum may be partially destroyed. When this tube has been undisturbed for some days, and then electricity passed through it, throughout the length of it there is nothing visible but the greenish-yellow light, similar to that which is seen in the V tube. But after the potash has been heated the tube is filled with striæ of pink light. When about to make the following experiment, I first tested the straight tube with electricity while it lay in a horizontal position, and found that it had not had time to fall back into the state of greenish-yellow light since the time I had previously heated the potash. There were still in the tube striæ of pink light, which extended from the end by which the electricity was admitted to the tube to within 3½in. of the outlet terminal. I now placed the tube in a perpendicular position, and admitted the electricity to it, so that the current went in by the bottom terminal and went out at the top one. While thus arranged the pink light extended from the bottom terminal to within 3½in. of the top of the tube. These 3½in. were filled with greenish yellow light, and this part of the tube was quite transparent. The pink striæ in the lower part of the tube were well defined, being much flattened spheres, and the highest of these striæ was so flat on the top that there was a well defined line between it and the greenish yellow light above. I now reversed the current of electricity, making it to descend through the tube. Immediately the whole appearance was changed. The great mass of the pink light was now at the top of the tube, and the 3½in. of greenish light at the bottom of it, with this very marked difference, that the pink striæ were no longer well defined—they seemed to run into one another, and there was no defined line between the pink striæ and the 3½in. of greenish yellow light at the bottom of the tube, and the latter was no longer transparent; the pink particles were seen descending through the greenish-yellow light. From these facts it is manifest that gravitation must be the force operating on the pink particles of potash, which, as far as known, are not acted upon by the earth's magnetism.

These experiments prove that the plus or inlet terminal of the current of electricity exerts the greatest amount of force in controlling the potash matter. Now, this is opposed to the statement of Mr. Crookes that the minus or negative terminal of these tubes exercises the most influence over the matter within them.

The tubes I have were made by the same party who made tubes for Mr. Crookes.—Yours, &c.,

JAMES JOHNSTONE.

8, Dalhousie-terrace, Edinburgh, 25th May, 1885.

ELECTRIC LIGHTING IN MILAN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a note from the *Tecnomasia Italiano* of Milan, published in your issue of 22nd inst., we observe several misleading statements which we would respectfully request you to rectify.

The Teatro alla Scala at Milan is, and has been since December, 1883, lighted by 2,546 Edison lamps, fed from the Edison Central Station in Via S. Radegonda, and operated by the Società Generale Italiana di Elettricità, Sistema Edison.

The installation at La Scala forms part of the general network of conductors parting from said Central Station, which has at present connected with it 5,600 Edison lamps, and seven Siemens arc lamps.

The arc lighting referred to by your correspondents was a provisory installation, consisting of a portable engine and a Gramme dynamo, feeding six arc lamps, with hand regulators,

Digitized by Google

which were used only for special scenic effects during ballet performances.

In fact, as a result of experiments made by our engineers at La Scala during the past season with arc lamps fed from the incandescent circuits of the theatre, this company has been requested in the future to furnish also these arc lights.

As noted above, we have seven Siemens arc lamps in regular operation on our incandescent circuits, which give great satisfaction to the consumers. Hoping you will accord the same publicity to our corrections as you gave to the article in question, we remain, yours, &c.,

SOCIETA' GENERALE ITALIANA DI ELETTRICITA', SISTEMA EDISON, L'Amministratore Delegato, G. COLOMBO.

Milano, May 25, 1885.

ELECTRICAL CONDITION v. RECENT SCIENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter of your correspondent, "S. E. R.," surprises me. Surely a reference to any of the thousand-and-one text-books of electricity published during the last twenty years would have supplied him with all the information he can desire.—Yours, &c., S. E.

ON OBSERVING AND RECORDING THE VARIATIONS OF A CURRENT.

BY C. W. S. CRAWLEY AND F. B. O. HAWES.

The authors have for some time past had occasion to observe and obtain a permanent record of the variations of certain currents, these variations being continuous and sometimes large, at other times very small compared to the total current. The method employed may, they think, be of use in similar work, such as earth currents, &c., the apparatus used having the advantage of being easily and cheaply constructed.

The measuring instrument employed was a non-astatic mirror galvanometer.

The first method adopted was using an ordinary scale for taking the readings of the galvanometer. One observer watched the scale, calling out the numbers to which the spot moved every time the current varied, a second immediately called the time, while a third recorded the two together in a book. This method required at least three observers, and was found quite unsuitable for quickly varying currents.

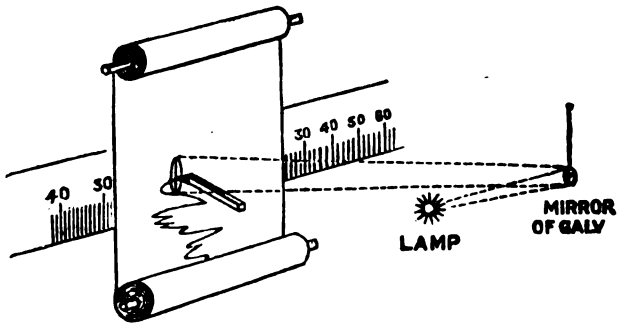

FIG. 1.

This was improved by the observer who read the scale having a key, which he depressed every time he called a number, *i.e.*, every time the current varied. The key worked an electric pencil, which made a mark on a moving Morse strip. Alongside the first pencil was a second one, in connection with a clock which sent a current every half minute, and thus made half minute marks on the same strip.

Only the numbers called had thus to be taken down, the times being afterwards determined from the dots on the Morse strip. In both these methods curves were afterwards plotted out from the data obtained; they were, however, found to be not sufficiently accurate, as there was occasionally a difficulty in determining the time, and in addition the curves did not show the speed of the increase or decrease of a current.

The following method was therefore finally adopted, by which very quickly varying currents were accurately recorded for hours at a time, only one observer being required, and the labour of plotting the curves afterwards being avoided.

Suppose a continuous sheet of paper were moved vertically across the scale of the galvanometer at a uniform speed, and the spot of light were followed by a pencil in its movements along the scale (Fig. 1), the result would be a continuous curve, showing every change of current. This would, of course, be impracticable, as the hand would be continually between the galvanometer and the paper, thus intercepting the spot of light; but by using a mirror, M, as in Fig. 2, the light may be reflected on to a sheet of paper moving horizontally across a table, when the curve may be conveniently traced.

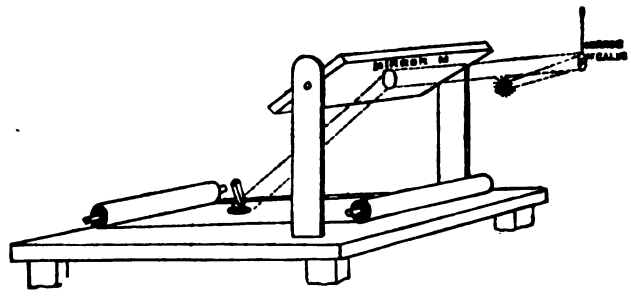

FIG. 2.

The paper was wound off one roller on to another, the former having an adjustable break on it, to keep the paper taut; and the latter being rotated by means of an endless cord and weight, so arranged that the weight might be pulled up without stopping the movement of the paper.

In Fig. 3 A is the roller carrying the paper, B and C weights of 10 and 1lb. respectively, and D a ratchet or clutch pulley, the driving weight B being raised by pulling the right hand cord, as shown by the arrow.

The roller A is also connected by an endless cord to a small pulley on the axle of an escapement wheel, controlled by a heavy pendulum, and, by altering the size of this pulley, any desired speed may be given to the paper. The speed generally used for earth currents was about three meters an hour.

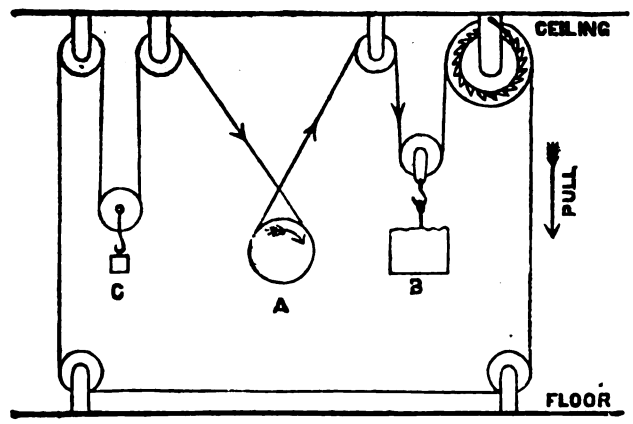

FIG. 3.

The spot of light was followed by a pencil, working against a brass bar (not shown) fixed across the paper at right angles to the line of motion, the centre of the spot being made to fall at the front edge of the bar by adjustment of the mirror *m* (Fig. 2). Close to the edge of the paper is another pencil (not shown) fixed on a spring, and working against the same brass bar, with which a mark was made every minute; it would be worked either by the left hand, by foot, or automatically by a clock.

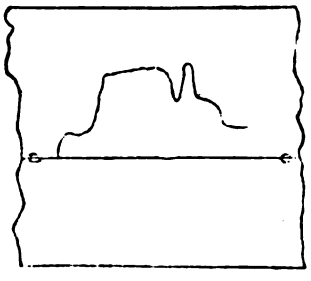
When taking a curve the position of the spot of light when at zero was first marked on the paper, and such data as the time of swing, constant of galvanometer, exact hour and minute of starting, &c., noted down for future reference. Zero was also taken every quarter of an hour throughout the readings, both to facilitate the drawing of the zero line when the curve was

Digitized by Google

finished, and to avoid any error due to slow shifting of zero from torsion of the fibre or other cause. The amount of curve lost in this latter operation was very small, it being done with practice in less than ten seconds.

The swinging of the needle caused some trouble at first. Thus, say Fig. 4 is the curve representing the true variations of the current, if the swings were unchecked it would give a curve somewhat like Fig. 5, and to find the true variations it would have to be replotted. This, besides taking time, would be liable to introduce errors, as it would be difficult to distinguish between the swings and the true variations.

FIG. 4.



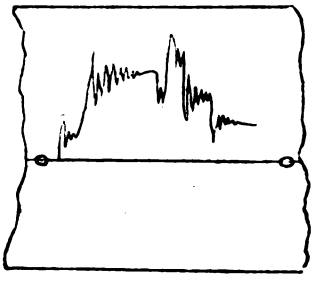


FIG. 5.

To overcome this inconvenience a coil of about fifty turns of wire was placed at a short distance behind the galvanometer, and joined up with a Leclanché cell through a double reversing or commutator key (Fig. 6) with two bottom contact pieces instead of one, as in an ordinary double key.

By depressing the right hand key the spot may be deflected to the right, and *vice versâ*.

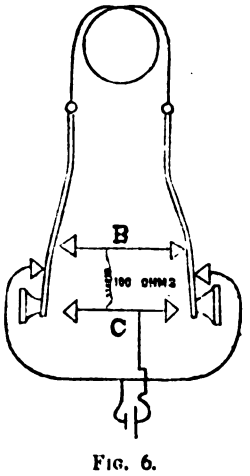

FIG. 6.

The use of the two bottom contacts is as follows:—When one of the keys is depressed, it first makes contact with the back contact piece B; the current then passes to the coil through a resistance of about 100 ohms (a couple of yards of 3 mil. G.S. wire). When, however, it is fully depressed it makes contact with the front piece C, and the full current is sent through the coil, the effect on the needle being then about twenty times as strong as when the key is half depressed. Now, supposing a steady current switched on to the galvanometer, sending the spot to the left, the right hand key must be depressed for a sufficient length of time to "break the swing," so that the spot may stop short at the point at which it would have finally settled down had it been allowed to continue swinging till it came to rest of its own accord. If the current is a strong one (or in the case of a varying current, if a variation be large) giving a considerable swing to the needle, the key is depressed to the front contact; but, if it be small, the key is only half depressed, using the back contact.

This method, it may be urged, tends to introduce errors, but it is not found to do so; for, with practice, the spot can be brought to rest at once at the right point, the speed at which it moves being the guide to the position at which it should be brought to rest.

This "swing check" has also been found to effect a very large saving of time in condenser and similar work, in which, after taking one reading the spot must return to zero before the next one is taken. It is also found useful in Mance's method for finding internal resistance, for the final readings in bridge work, &c.

(To be continued.)

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(Continued from page 30.)

CHAPTER V.—*Suggestive.*

25. Discussion of Sir William Thomson's contact-electricity limit to the size of atoms, from the new standpoint.
26. Suggested mode of ascertaining the heat of formation of brass or other alloy.
27. Attempt to determine size of atoms from heats of amalgamation and thermoelectric data. Possible mode of measuring latent heats of liquefaction for metals at ordinary temperatures.
28. Consideration of limit of thinness of a metal sheet exposed to air, and estimate of molecular dimensions therefrom.

Size of Atoms.

25. I may now claim to have accomplished my task; and terminate this long paper; but there are several interesting points which arise in connection with Sir W. Thomson's deduction of a limit to the smallness of atoms from contact data, and these I may be permitted to indicate. Indeed it evidently becomes a question whether or not his argument remains quite valid if the chemical-strain view be taken of Volta's force.

Let us then inquire whether any modification has to be made in Sir Wm. Thomson's argument, if the hypothesis set forth in this paper be adopted. He says (virtually), Take a number of plates of zinc and copper of specified thickness, arrange them alternately like the leaves of a book with the covers doubled right back, and then shut the book. Directly they touched at one edge they became oppositely electrified and attracted each other, and therefore did work as they approached. By making the leaves numerous and thin enough, and shutting them up close enough, any required amount of work can be thus done with given quantities of metal, provided the thin plates retain the same properties as masses of metal possess; *i.e.* provided they are not only a few atoms thick. So far there is no possible objection; but Sir William proceeds to consider the attraction as depending on the affinity of zinc for copper, and the work he requires of his plates is that evolved in the formation of brass. But if we regard the attraction as depending on the difference of combustion energies, Zn/O – Cu/O, we must, to keep the charge constant, not only take the plates several atoms thick, but we must suppose films of air of sufficient thickness to preserve their normal activities in the way of chemical strain to be shut up with the plates. Given these, the amount of work he has calculated would certainly be done in shutting the book, and a corresponding amount of heat generated. But would this heat have anything to do with the making of brass? So far as I can see, nothing whatever.

If we intend to make brass, must we not regard the air surrounding the plates as a simple accident, and imagine all air-films removed before beginning the operation? Work with the zinc and copper plates in absolute vacuum, where (on my hypothesis at any rate) the only difference of potential between them is a minute thermoelectric one; there will be an attraction caused by this difference of potential, and work will be done in shutting the book, but to get any appreciable amount of heat the plates must be terribly thin. How much heat really is produced in the formation of brass I don't believe any one knows; but if it be enough to warm the metals sixty degrees, the lower limit to the size of atoms becomes greatly depressed.

In a note near the end of this paper I show that a rise of from ½ to 2 degrees is all that is probable, on the usual estimate of atomic dimensions;

* Reprinted from the *Phil. Mag.* for May.

Digitized by Google

the smaller evolution of heat being caused by alloying the metals at 10° C., the larger being produced by alloying them at 400° C.

26. *Is* there much heat produced in the formation of brass? Is there any way of attacking the question simply? The only way which has occurred* to me is to dissolve brass in acid, and to see whether one gets appreciably less heat than by dissolving its constituent copper and zinc separately. When an alloy is dissolved, I suppose the affinities of its constituents are unloosed, or the combination undone; hence the heat developed during the solution of an alloy, subtracted from that produced during the solution of its constituent metals and mixing of those solutions, ought to measure the heat of formation of the alloy. Dr. Forster Morley, of University College, London (also on the boat), said he might be willing to undertake this observation, which is doubtless a delicate one, for he was engaged in some thermo-chemical researches. It may not be practicable for the actual case of brass, because of the complication and uncertainty introduced by secondary products, but a better pair of metals may no doubt be readily found.

Adhering to zinc and copper as convenient for explanation, the argument, though obviously not the order of experiment, will stand as follows:—Take definite weights of zinc and copper, dissolve them separately, getting heats H_1 and H_2 respectively; then mix the solutions, getting a possible further heat-production h. This is one plan of passing from separate zinc and copper to a solution of a salt of brass.

Next take the same weights of zinc and copper as before and alloy them, getting heat H; then dissolve the brass in the same acid as before, getting heat H_3. This is another plan of passing from separate zinc and copper to a solution of a salt of brass.

Now, unless external work and secondary products are different in the two cases, we are justified in writing the heats evolved in the two cases equal:—

$$H_1 + H_2 + h = H + H_3.$$

H is the unknown quantity to be determined, and its determination involves four separate measurements, H_1, H_2, H_3, h.

The only one of these at all easy to observe is h, and this my assistant, Mr. Butler, has done. Proportions of zinc and copper sulphate, containing equal weights of zinc and copper, are dissolved in as little water as will keep in solution any double salt that may be formed on mixing. The zinc sulphate is enclosed in a thin bulb or tube inside the other solution, and left, screened from stray heat, for some hours. The bulb is then broken, or the liquid otherwise blown out of it, and the liquids mixed. No certain change of temperature so great as a hundredth of a degree has been observed.

27. In thinking over what metals were more suitable, it struck me that the heat of formation of amalgams was a subject easy of direct attack. I therefore, as a preliminary, have dissolved a little granulated tin in mercury. Of course the latent heat of liquefaction of tin has to be allowed for, and the actually observed result is a cooling; but I hoped that the cooling observed would be less than what the latent heat would account for, and that I might then calculate the real evolution of heat due to combination. Unfortunately the only data I know of with reference to the latent heat of tin relate to its ordinary melting point, at which point it is given by Rudberg as 13·3, and by Person as 14·25. We have no ground whatever for believing latent heat to be constant, and I am therefore utterly in the dark as to what the latent heat of tin at ordinary temperatures may be. That liquid tin could be super-cooled to ordinary temperatures without solidification is unlikely. I give, however, the data of my experiment (which was carefully performed) in case better latent-heat data are known to some one else:—2·10 grammes of thin granulated tin at 12°·4 were dropped into 502·00 grammes of mercury at a steady temperature of 10°·85, contained in a large thin protected test-tube, of which the part sharing the temperature of the mercury weighed 8 grammes. After solution, which took ten minutes, the resulting temperature was found to be 8°·82. Three minutes later it had risen to 8·99 from surrounding influences. The thermal capacity of the immersed part of the thermo meter was equivalent to ·48 gramme of water.

Working on these data, and taking the specific heat of tin as ·056, latent heat 14·25, specific heat of glass ·19, and of mercury ·033, we find:—

Heat disposed of in cooling and liquefying tin ..... 30·45 units.
Disappearance of heat actually observed ..... 43·57 ,,

More than can be accounted for without any combination-heat at all! This is rather depressing; but it only shows how wrong is the estimate of 14·25 for the latent heat of liquid tin at 10° C.

Ignorance of the true latent heat thus effectually prevents our obtaining any information whatever, about the heat of combination of tin and mercury, from the experiment. It seems, indeed, easier to observe the combination-heat by a process of dissolving the amalgam and the metals separately in acid, as already explained for brass, and then to use the above experiment to calculate latent heat from. One might perhaps thus get the latent heats of fusion at various temperatures for metals soluble in mercury.

Another alternative, however, presents itself. Instead of trying to reduce the latent heat to ordinary temperatures, one might form the amalgam at a temperature just below the melting-point of tin, and obtain, if possible, the net evolution of heat then.

Suppose the heat of combination of the 2·1 grammes of tin with mercury to be somehow or other determined, we have next to suppose the amalgam made otherwise, bringing the molecules together in a reasoned way. Let the same quantity of tin be brought to within molecular distance of the mercury in successive pieces of very thin foil, first made to touch at one corner and then laid down.

* It occurred in conversation with Prof. S. P. Thompson and Dr. J. A. Fleming on board the Quebec excursion steamer 'Canada,' and I am unable to say who suggested it.

It is quite true that each flake would be charged with a Volta E.M.F. of, say, ·6 volt, and so would attract the mercury and do a certain amount of work in laying itself down. But it is not fair to compare an operation thus conducted in air with the dropping of a solid mass of tin into mercury: to be able to compare the two operations, one must perform the foil experiment in absolute vacuum. This being done, the contact E.M.F. is no longer ·6 volt, but only about ·00015 volt according to the experiments of Matthiessen. Good data for this quantity are, however, wanting. Mercury is not one of the metals included in Prof. Tait's series. It was observed by Gaugain; and by rather hypothetical deduction from his numbers, as given pictorially in Wiedemann's *Elektricität*, I make the tin-mercury Peltier force 1·75 millivolt at 10°*.

Taking one of these numbers (15,000 or 175,000 in C.G.S. units), or a better one when determined, we can calculate how near the given mass of tin must be brought to the mercury in order to generate the actual heat of combination, provided one knows the specific inductive capacity of absolute vacuum†. But I do not know it. Thus the supply of data for this case is distinctly unsatisfactory.

28. Let us try whether we cannot do better with a single metal exposed to air, not troubling about the contact of two metals, which is unnecessary, but simply considering one metal in contact with air.

Take a gramme-equivalent of any metal, say 65 grammes of zinc, and imagine it rolled out into a thin sheet of foil of area A. The difference of potential between it and the air being V in electrostatic units, $\frac{V}{300}$ in volts, its charge will be $\frac{2AV}{4\pi x}$, where x is the distance between it and the air, a quantity of molecular magnitude. The electrical energy of this charge is $\frac{AV^2}{2\pi x}$, which must therefore have been the electrical work done (*i.e.*, the amount of potential chemical energy transmuted into electrostatic energy) in spreading out the zinc over so much surface. [Capillary tension is part of the *mechanical* work done.]

Now let it be rolled so thin that every atom of it is in contact with air, *i.e.*, let its thickness be also of molecular magnitude x. We can regard its potential energy in two ways: either as chemical or as electrical. Chemically its energy, measured by heat of combination, is

$$46{,}000\ VJ,$$

where V is expressed in volts. Electrostatically its energy is

$$\frac{A}{2\pi x} \cdot \left(\frac{V}{300}\right)^2.$$

Equating these two values, and writing for the quantity of metal $m = Ax\rho$, we have the general relation

$$mV = \cdot 828\ \pi\ \rho\ x^2\ J \times 10^{10};$$

whence, taking $m = 65$, $\rho = 7$, and $V = 1 \cdot 8$, we get as our estimate of linear molecular dimensions,

$$x = 4 \times 10^{-9}.$$

The data in this calculation are all very definite; hence, if the reasoning is legitimate, this estimate ought to be a pretty good one. It is true that another metal would give a rather different estimate, unless $\frac{mV}{\rho}$ were constant for all; but for ordinary methods—*e.g.* zinc, iron, copper,

* Since this was in type a paper by C. L. Weber has appeared in Wiedemann's *Annalem* for November, 1884, on the thermoelectric properties of amalgams, in which mercury itself was examined; and from the data there recorded, together with Tait's value for copper, I reckon the thermoelectric value of mercury at t° C. as

$$431 + \cdot 5t \text{ absolute electromagnetic units.}$$

Whence the Peltier force at the same temperature is

$$1181 + 5 \cdot 68t + \cdot 005t^2 \text{ microvolts.}$$

The Peltier force between tin and mercury at 10° is therefore 123,800 absolute units, or 1·24 millivolt, which agrees well enough with the rough estimate above.

† Taking this as 1, and assuming the estimate of molecular dimensions hereafter established, and working backwards, one can show that the Peltier force of tin and mercury at 10° is connected with the heat of combination of our 2·1 grammes of tin with the 502 grammes of mercury by the relation

$$J\Pi = 3 \cdot 6 \times 10^6 \sqrt{H}.$$

The two rough estimates of $J\Pi$ deduced from Matthiessen and Gaugain respectively (15,000 and 175,000) thus give H as about $\frac{1}{4}$ and $\frac{1}{18}$ of a unit respectively. Either of these is too small a quantity to be observed in the process of dissolving tin in mercury; so neglecting it we get, from that experiment, the latent heat of molten tin at 10° C as 20·4. Another experiment made in a similar way gave 19·6.

If the above reasoning be regarded as legitimate, a combination of thermoelectric measurements with observed heats of solution in mercury may furnish a means of estimating latent heats of fusion at various low temperatures in general.

Working back similarly to the heat of combination of 1 gramme of copper with 1 gramme of zinc, we calculate ·077 unit as the heat developed at ordinary temperatures; only enough to raise the mass of brass formed through three eighths of a degree Centigrade. At a higher temperature, such as 400° C., the Peltier force for these metals is greater, being 4600 microvolts, and the calculated heat of combination is then $\frac{1}{2}$ of a unit per gramme of each, sufficient to raise the whole mass of metal through nearly 2 degrees Centigrade. This, then, is the sort of elevation of temperature one may expect in making brass at a temperature of 400°.

Digitized by Google

mercury, silver—this is not so outrageously far from being the case; though discrepancies arise with such metals as sodium on the one hand, and platinum on the other. But it is very doubtful whether platinum could be regarded as an oxide, however thin it were beaten; and sodium would probably take fire long before the proper molecular thinness was reached.

The several estimates of Sir William Thomson for the size of atoms were given in 'Nature,' March 1870, and are reproduced in Thomson and Tait, Part II., Appendix F. In a lecture on the size of atoms delivered at the Royal Institution in February, 1883, he restates these estimates with slight modifications thus:—

If atomic dimensions are comparable with 10^{-8} centim., brass would rise 62° C. at the instant of formation; while if atoms are so small as $2{\cdot}5 \times 10^{-9}$, it would rise 1,000° C. Hence 10^{-8} is to be regarded as a limit of smallness.

A soap-film so thin as 10^{-8} centim. would raise itself 280° by collapsing; therefore there are not several molecules in this thickness.

The theory of gaseous collision, combined with the density of liquids, suggests a range lying between 7×10^{-9} and 2×10^{-9}.

The dispersion of light seems to require atomic dimensions to lie between 10^{-7} and 10^{-9}.

The final estimate made by Sir William is something between

$$2 \times 10^{-7} \text{ and } 10^{-9}.$$

But if the reasoning in the present paper be admitted as correct, it would seem possible to reduce this range of uncertainty, and to make an even more precise estimate.

PHYSICAL SOCIETY.—May 23.

Professor Guthrie, President, in the chair.

Dr. A. H. Fison was elected a member of the Society.

The following communications were read:—"Experiments showing the Variations caused by Magnetisation in the length of Iron, Steel, and Nickel Rods," by Mr. Shelford Bidwell. The subject of the extension and retraction of bars of iron and nickel under the action of magnetic force has been investigated by Drs. Joule and A. M. Mayer and by Mr. Barrett. In the present experiments the magnetising force has been increased, with the result of bringing out some striking and novel characteristics. The apparatus employed consisted of a vertical magnetising helix considerably longer than the experimental rod, the latter forming the central portion of a compound rod, the two ends being of brass. The lower end of this rod is plane, and stands on a firm support; the upper end is a knife edge, which bears against a brass lever 18cm. in length, about 1cm. from the fulcrum; the portion of the rod to be examined is in the central portion of the helix. The above lever is furnished with another knife edge at the end which acts in a similar manner on a second lever, at the extremity of which is a small mirror. A lamp and vertical scale being placed at a distance of 470cm. the slightest motion of the mirror could be read with great accuracy, an elongation of the bar amounting to 1/102·000th mm. being easily detected. A few of the more important results are as follow:—In the case of soft iron the bar continually increased in length till nearly saturated, up to which point Mr. Joule had traced it, but then it reached a maximum, decreased, and continued decreasing to the limit of the experiments, at which point the retraction was about double what the extension had been. The effect depended upon the thickness of the bar, an increase of diameter diminishing the maximum extension and increasing the critical magnetising force, or that force which produced the maximum extension. The results seemed to show that this extension varied inversely as the square root of the diameter of the bar. The general behaviour of steel was the same as that of soft iron; but the critical point varied with the hardness and temper of the metal, appearing to be a minimum for steel of yellow temper. The results of experiments upon nickel coincided with those obtained by Prof. Barrett, the effect of magnetisation being to cause a continuous retraction greater than that obtained with soft iron. In answer to Prof. HUGHES, who believed that the effect of the coil was always to produce *retraction* of the bar, the *extension* at first being due to the molecular arrangement of the particles during magnetisation, Mr. Bidwell further described an experiment showing that the action of the coil was to produce the *extension* of a magnet. Two thin strips of soft iron fastened together at the ends, their central portions being about 2cm. apart, were placed in the coil. On making the current the ends were drawn out, the sides coming together. Prof. FORBES suggested that the effect of thickness was really owing to the irregularity of magnetisation produced by the ends, and that in future experiments the middle of the bar only should be examined.

"On the Spectral Image produced by a Slowly Rotating Vacuum Tube," by Mr. Shelford Bidwell.

"Note on the Action of Light in Diminishing the Resistance of Selenium," by Mr. Shelford Bidwell. As the result of their investigation upon the behaviour of selenium, Messrs. Adams and Day arrived at the conclusion that it conducted electrolytically. Since it would necessitate the assumption that selenium is not an element according to accepted theories caution must be exercised in accepting that view. It seemed possible, however, that since the selenium in the cells had always undergone a prolonged cooking in contact with the metal terminals, selenides of these metals might exist in the selenium, forming a kind of network, and thus affording conduction through the mass, which without the cooking is non-conducting. It had not been possible to test this directly, but a somewhat analogous case had been tried. Some precipitated silver had been heated for some hours with sulphur and the clear liquid poured off. A cell was then made by coiling two silver wires side by side upon a strip of mica, the spaces between them being filled with the prepared sulphur, which would contain a small quantity of sulphide of silver. It was found necessary to reduce the resistance of the cell by placing a small strip of silver leaf over the sulphur and cooking it again. The cell thus prepared was very sensitive to light; by burning a piece of magnesium near it, the resistance was reduced to one-third. Mr. CLARK said that Mr. Bidwell's cells probably contained sulphides of copper or silver, substances which the researches of Faraday had shown conducted electrolytically in the solid condition. On the other hand, Cu_2Se and Ag_2Se conducted like metals, and were probably often present in the ordinary selenuim light cells. Mr. Clark thought that Mr. Bidwell's paper raised this question:—What influence had light upon the electrolytic conduction of Cu_2S and Ag_2S, and upon the metallic conduction of Cu_2Se and Ag_2Se?

"On Certain Cases of Electrolytic Decomposition," by Mr. J. W. Clark. The first part of this paper consisted of a critical examination of the behaviour of those substances which have been described as exceptions to Faraday's laws, with the object of generalising as to the condition of internal or molecular structure corresponding to their electrical properties. The second part described an experimental investigation into the nature of the conduction of fused mercuric iodide and mercuric chloride, both of which were stated to undergo electrolytic conduction. Decomposition and recombination of the products of electrolytic action may, however, follow so closely as to simulate metallic conduction. The first product of electrolytic decomposition of mercuric iodide was stated to be iodine and mercuroso-mercuric-iodide (Hg_4I_6), which latter, under the continued action of the current, yields free mercury. Similarly it was found that fused mercuric chloride, when electrolysed between graphite terminals, split up into chlorine and mercurous chloride. Metallic conduction—*i.e.*, conduction without decomposition in fused compound solids, therefore, appears to be unknown.

Note on "Electrical Symbols," by Mr. J. Munro.

SIXPENNY TELEGRAMS.

In the House of Commons on Friday evening last, Mr. Shaw-Lefevre moved the second reading of the Telegraph Acts Amendment Bill.

Mr. W. Lawrence, who had an amendment on the paper to the effect that, if any charge is made for addresses, it should be a fixed one, and not varying with the number of words, figures, or letters, and that such charge should not exceed threepence, said he would not move his amendment, but he hoped that the Postmaster-General would consider the matter during the recess.

Mr. Puleston said he believed that under the Postmaster-General's scheme there would be such a diminution of telegrams that the loss to the revenue would be greater than from free addresses.

Dr. Cameron suggested that in large towns the Post Office authorities should codify the streets. Such a code might be published, either in a separate form or in the "Postal Guide"; if this arrangement were adopted, the address would be got through in one word.

Mr. Shaw-Lefevre said this discussion was only a rehearsal of the debate that would arise on the amendment of the noble lord opposite (Lord J. Manners), and he, therefore, hoped hon. gentlemen would excuse him if he did not now reply to all the points that had been raised. He did not understand the hon. member for the City of London to be opposed to the principle of the Bill, but only to propose an alternative plan. When in Committtee he should be happy to consider fully any amendments that might be brought forward provided they did not involve a greater burden on the Telegraph Department than the plan laid down in the Bill. It had been urged that the Post Office and the telegraph business should be considered as one, and that the profits of the one might very fairly be applied to cover the loss on the other—that any loss in the Telegraphic Department ought to be recouped by the profits of the Post Office. That was a principle that had never been recognised by that House. Since the purchase of the telegraphs it had been well understood that the Telegraph Department should be treated by itself, and that, as far as possible, it should be made self-supporting after paying reasonable interest on the purchase money paid for the acquirement of the telegraphs. He thought that a sound principle, and was not prepared to depart from it. It would not be right or fair that the general public should be taxed in order that a small part of the community should be able to send their telegrams at a price much less than the cost price. The telegraph service was not now in so flourishing a condition as it was two years ago. Owing to the increase of remuneration paid to the *employés*, and also to the competition with the telephone, there had been a great reduction in the profits of the telegraph service. They had fallen from £450,000 to at the outside £250,000 a year, and out of this £250,000 there remained to be paid the interest on the £11,000,000 which was paid for the purchase of the telegraphs, and this reduced the interest to a very low rate. The plan that he now proposed had been carefully worked out by experts in the Post Office, and it was calculated that, allowing for an increase of 30 per cent. in the number of messages sent, there would during the first year be a reduction of the Telegraph Department profits by about £180,000, and this would reduce the profits to £70,000 a year, which was a very small margin of profit on a business of such magnitude. The reduction of the price of telegrams from 1s. to 6d. really involved a much larger financial risk than most persons supposed. There were certain expenses connected with telegrams which were incurred whatever the length of the telegram—such as the receipt of the telegram over the counter and its delivery within the radius. It had been estimated that the average necessary cost of each telegram, irrespective of its length, was 2½d., and that left the price charged now and to be charged under this Bill 9½d. and 3½d. respectively, and therefore the proposed reduction was really about one third. Every telegram was accompanied

Digitized by Google

by certain official words, eight in number, necessary for the purposes of information to the department. The average length of addresses had been found to be 11 words, and therefore the average length of an ordinary message under present circumstances was 39 words—the message 20 words, the address 11, and the official words 8. The Bill proposed to reduce the number of words to 20—namely, 12 words in the message and address, and the eight official words; the length of the message would be reduced from 39 words to 20 words, or one-half, while the price was being reduced from 9½d. to 3½d. It was accordingly neceessary that there should be some economy of work. It was well known that there was an enormous waste of words in the sending of telegrams, and an amount of useless labour was thus thrown on the department. A large number of telegrams had been carefully examined, and it was found that the number of superfluous words amounted to about 25 or 30 per cent., and a large proportion of the superfluous words occurred, it was found, in the addresses. These, on an average, now consisted of eleven words, and it was the opinion of competent persons that the address as a rule need not occupy more than five words. A saving of six words could thus be effected in each telegram, which was estimated to amount in the year to about £200,000. He quite admitted that free addresses had some convenience, but on the other hand they were a very expensive luxury, as they cost the service £200,000 a year. He had observed in the newspapers various alternative suggestions to his proposal. They all resulted in loss to the department. The hon. member for the City of London who last spoke proposed that a free address and ten words should be given for 6d. He had had the cost of that calculated. It showed that, assuming an increase in the number of telegrams sent in consequence of the reduced tariff to the extent of 30 per cent., the loss to the service would be £560,000 a year. That was not the worst part of the case, for a tariff of that kind would enormously stimulate business and would greatly increase the working expenses. They believed that it would be impossible to send free addresses and ten words for 6d., without in a short time, by reason of the enormous increase of business, incurring a much greater loss than £560,000 a year to the department.

In answer to a question by Mr. Hubbard as to whether he calculated the loss to the department by rule of three, Mr. Shaw-Lefevre said that the figures he had quoted were from calculations made by the officials of the department. The loss from the hon. member's suggestion would be so great, therefore, that a tariff of that kind was altogether out of the question. The suggestion of the hon. member for Devonport, that there should be a free address and six words for 6d., it had been calculated would cause a loss of £110,000 a year more than the proposal submitted. The tariff proposed by the hon. member for the City of London, who spoke first, that a free address and five words should be allowed for 6d., would result, as far as he could make out, although it was somewhat difficult to state the actual cost, in a loss of £100,000 a year more than his proposal. He thought, therefore, that the House would be of opinion with him that these various suggestions were all out of the question without inflicting heavy loss upon the department, and therefore upon the public revenue. The tariff which was proposed under their Bill was a word rate of a halfpenny a word, with a minimum of twelve words for 6d. It was calculated that five words would on the average be used for the address of the message. That was the opinion formed from a careful examination of the existing telegrams by officials of the department. They could not but think that there was a good deal of misunderstanding upon the subject of addresses. The belief had been expressed by the officials that the sender's address would in future average only one word. In support of that view they had before them the experience of foreign telegrams and also telegrams to France and Germany. It was found that foreign telegrams sent to this country in a large majority of cases contained no address at all of the sender. The message itself no doubt showed the receiver from whom it came. A large proportion of the foreign telegrams had only one word to indicate the sender. It was believed that in future, if the proposal of the Bill were adopted, senders would in a very large proportion of cases indicate themselves by one word, and in very few cases would it be necessary to use more than one word. If it were necessary for the sender of the telegram to give a full description of his address, that was information that ought to be contained in the text of the message and ought to be paid for. The hon. member for Salford had quoted the unanimous resolution of the Manchester Chamber of Commerce approving the Bill, and he had asked that in future the suggestion of the Chamber should be adopted—namely, that numbers should be counted as one word, and that where it was necessary the sender's name should be inserted in the address. He was in a position to answer both those questions in the affirmative, and they would in future be the rule. Different words in a number would therefore in future be counted as one word. As regarded the post office to which the message was sent, it was not necessary to put it in the address, because it was always sent for official purposes, and there was no necessity that the sender should put it in as one of the words of the message. While he believed that on an average one word would indicate the sender, a careful examination of telegrams led to the belief that the receiver would be indicated on an average by four words. A large proportion of the foreign messages sent into this country contained only three, and in some cases four, words of address. No great hardship would result if an extra word or two had to be inserted in an address, as the rate would be two words for a penny. The objections which had been raised to this proposal rested mainly on two points. In the first place it was said that the abolition of free addresses would lead to uncertainty and to extra labour on the department; and, secondly, it was said that it would be a hardship on certain classes of persons. As to the first point, the officials in the department did not think that any extra difficulty would be thrown on them, judging by the large experience they had had of foreign telegrams, and also to the fact that, although the addresses in those telegrams were shortened, little confusion or trouble had resulted. There was also the experience of foreign countries to guide them, where a word-rate prevailed. In Germany there was no free address, and it was found that addresses averaged only four words; again, in France a word-rate only existed, and no difficulty was found with respect to the address. The other objection, that this proposal would press hardly on certain classes of people, in this country, was one into which he went at some length in introducing the Bill. With some difficulty he had obtained a number of telegrams sent by working people, and although it appeared that their addresses averaged somewhat longer than those of other telegrams, it was found that about 60 per cent. would admit of curtailments of the addresses without any trouble or difficulty being occasioned. It had been pointed out that the proposed tariff did not look so favourable as the present tariff. By the present tariff 20 words were allowed for 1s., with a free address, whereas under this proposal 24 words would be allowed for 1s., with no free address. But the higher they went in the tariff the more favourable it appeared, and, moreover, it should be recollected that between 6d. and 1s. there were several steps. It was assumed that there would be only the 6d. and 1s. rate, and nothing between; but that was not the case, and any number of words between 12 and 24 would be inserted in the message at 1d. for two words. They believed that a very large proportion of the messages sent—about 30 or 40 per cent.—would be at the 6d. rate. But they also thought that a very large proportion would be sent the cost of which would be between 6d. and 1s. They thought that under the proposed tariff not more than one telegram out of ten would be sent at the 1s. rate. Before resuming his seat he wished to say that to his knowledge no important commercial body had petitioned against the Bill, while, on the other hand, the Associated Chambers of Commerce and the Chambers of Commerce of Manchester and Glasgow, and of other large towns, had spoken of the tariff proposed as one very favourable to the working classes. He trusted that the House would not reject the boon that he was able to offer to the country. He should be perfectly ready to consider in Committee any alternative tariff that might be suggested which would not impose a greater burden on the finances of the department, but he should not be able to agree to any tariff which would have that effect, for such a tariff could not be established without infringing on the principles that the telegraphic service should be independent of the postal service, and that it should be conducted so as to return a respectable profit on the amount invested by the State.

In the course of the discussion which followed Mr. Hubbard observed that when the State originally undertook the management of the telegraph service the receipts improved to such an extent that two years ago the surplus revenue amounted to 3 per cent. on the £10,000,000 which had been invested. Mr. Ruston said an instance of the way in which free addressing might be abused had recently come under his notice. A telegram was sent to him in which the addresses occupied twenty words, and eight of the words in the sender's address ought certainly to have been placed in the body of the message. He strongly approved the proposal that four or five figures should be included in the body of a message as one word. This change, if agreed to, would be an immense boon.

Mr. Warton thought that all sorts of dangerous telegrams might be sent under the scheme without any means of identifying the sender.

Mr. Tomlinson remarked that it was his firm belief, founded upon observation not so much in London as in the provinces, that the telephone would come in time more and more in competition with the telegraph. At all events, so far as commercial telegrams were concerned, there could be no doubt that the telegraph would give place to the telephone, and possibly the large increase which was expected in the telegraph business might not result.

The Bill was eventually read a second time, and the Committee stage fixed for the 4th of June.

COMPANIES' MEETINGS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The fourth ordinary general meeting of the Consolidated Telephone Construction and Maintenance Company was held at the Terminus Hotel, Cannon-street, on the 26th inst., under the presidency of Mr. C. L. W. FitzGerald.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting and the minutes of the last meeting.

The CHAIRMAN said: The present Board have done their best to submit as intelligible a balance sheet as they possibly could. You are all aware that the accounts are rather complicated, and it has cost us no little labour and trouble to reduce them to something which, I think, we may fairly say one can understand. I should like to point out a few things in the balance sheet and the revenue account. First of all, you will see that the capital has been reduced according to the resolution of the meeting in December last. You will see on the other side an item "subsidiary companies," with an asterisk standing against it—£47,000. That item will be expunged when we hold the next meeting, and in its place will appear £31,500 of 5 per cent. debentures of the Telephone Company of Austria, and £20,000 of 5 per cent. preference shares of the Edison-Gower-Bell Telephone Company. I may say safely that both the interest on these debentures and the preference shares will be paid, and therefore you will receive money from that source. We have separated the ordinary debtors of the Company from the amounts owed by subsidiary companies, and that amount of £4,394 is from companies in England and one or two other companies. Our principal debtor really is the United Telephone Company. We should have been

Digitized by Google

very much gratified, indeed, had we been able to pay you a dividend, but the fact of the matter is that the requirements of this business are so vast that I think it would be undesirable, when we have just rescued this Company, practically, out of the Bankruptcy Court, to divide up the profit we have made. If you turn to the revenue account you will see that the manufacturing profit was £8,300. After deducting certain expenses and writing off from that profit £1,500 against goodwill and patent rights, we have a balance of £5,200 to credit of profit and loss. I can point out to you a mode of paying a dividend if it pleases you to do so—that is by the shareholders of this Company purchasing from the Company the £14,000 River Plate debentures standing to the credit of our securities. I am informed by the auditor they are available for sale and division among you as a profit to the extent of, say, £5,000. If this course is not taken, I think it would be undesirable to divide up the profit we have made, for I should point out to you that our business is not alone manufacturing. We have three very important businesses abroad. When I say "we," I mean you have shares in subsidiary companies, each of which has a large and widely extending business. If we do not support those subsidiary companies you would find that our business in the future, when the term of the patents expires, would diminish very much. I have always got my eyes fixed on that point, and feel that we must get a large proportion of our profits from the income to be derived from the exchanges abroad—in other words, from the River Plate Telephone Company, the Austrian Telephone Company, and the Edison-Gower-Bell Telephone Company in Portugal. In the revenue account there is an item legal expenses, and we shall not have to incur a gigantic sum like that again. In reality £1,150 has been paid. A certain sum was reserved from last year's accounts for legal charges, but it has fallen to the lot of this Board to provide the money to pay it. There is also an item of expenses for the committee of investigation (£260), and we shall not have to pay that again. I hope, therefore, that the debit side of the account at our next meeting will be more favourable. I feel myself that it will be, and I mean to do my very best to reduce the expenses in every possible way that I can. Our having had several meetings this year has also added very considerably to the expenses of printing and stationery. As to the subject of manufacturing, I am very happy to say, as to home manufacturing that we are doing a large and increasing business, and I believe, so far as we can judge, that that business will increase more and more. Our output every week is certainly something very good now. When I first joined the Board it was very small—sometimes only £100, while now we have increased it up to occasionally £1,000 a week. I fancy that the cause of the increase here is the extension of the radius which the Postmaster-General has granted to the telephone companies. In the United States I find, on looking through a report, that there are no fewer than 128,000 telephones running, while in the United Kingdom there are only 12,000. Surely in the five years to come, while we are sole manufacturers of the instrument, the telephone must make a start—at all events, we must hope it will. We have at this moment a large order from the Postmaster-General. Mr. Preece, the electrician, has stated to me that he has never had a better instrument turned out of the factory than at this present moment. He is extremely satisfied with it. I may also say that we have independent testimony from Sydney, in Australia, where gentlemen are using the Consolidated telephone in preference to any other. The Canadian Government have ordered of us lately a small number of instruments, and with that order we received a letter saying that they are highly pleased with the transmitting power of our instrument. We look to that to get us some special orders in the future. Abroad there is not the slightest doubt that we could do a large business, but at a very small profit, and I think it would be unwise at present to press that business too much. We are doing a little on the Continent, and we have received offers to do business from Sweden, Italy, and Holland, but the profit is so small, that while we have got a fair amount of business here to occupy us I think it would be unwise to accept such orders. The matter, however, has our attention. We have entered into negotiations with a certain body of gentlemen to execute a large order for Canada. If we get that it will take a very considerable time to execute. Before I quit this subject I cannot help saying a word of praise for our general manager, Mr. Mason, to whom I assure you we are all very much indebted for the manner in which he has worked our business. With respect to the exchanges abroad, we give at the end of the report a statement of what we have done in the course of the year. I think that alone as a business should prove highly satisfactory. We have increased the subscribers to the exchanges by 914, with an increase in the annual income of £6,472. That has been done at a capital expenditure of about £22,000, roughly speaking. The manager in Austria, who is present at this meeting, having just arrived from Vienna, states that we have there no fewer than 870 subscribers, and that there are 284 persons waiting to join the exchange. I should like to point out that, according to Mr. Krause, when we have got 1,100 subscribers connected up and paying, the revenue to the Austrian Company will be £9,000 and the working expenses about £3,870, leaving in round figures a net profit on the business of £5,000. I think if we consider that all these exchanges abroad are gradually working up to a paying position, we have every reason to congratulate ourselves, because in due time there is no doubt that those businesses will be one and all returning us a large income. While on the subject of the Austrian Company I would mention that one of the Directors, Mr. Bateman, went out to Austria to examine and see what the property there was, and he has come back with a very high opinion indeed of that business. We have, through introductions which members of this Board have obtained, got into communication with the Minister of Commerce (Baron Gino) in Vienna, and we have greatly improved the status of the Company by doing so. As you are aware, at one time the relations between this Company and the Austrian Government were nearly being broken off and the concessions forfeited. At Lisbon and Oporto matters are progressing satisfactorily. The number of subscribers there has increased during the past year by 284, while the gross rental has increased by £1,559. There is only one other point I would allude to with respect to the Edison-Gower-Bell Company, and that is that they are remitting money home, and Mr. Danvers says he hopes to be able to send between £2,500 and £3,000 this year. I have had a letter this morning from the River Plate from Mr. Powers, who says that everything is going on very splendidly with them there. The exchange question is injuring us to some extent, because there is no possibility of sending back money from that part of the world with the rate 33 per cent. against you. At the present moment we are examining closely into all the details of expenditure, and I hope and trust that, with the continued increase of the manufacturing business at home and abroad, and the exchanges all working into paying concerns, the absolute success of the Consolidated Company will be secured in the future. I believe it will, and we shall do all that we can to keep this business in the sound position to which we have brought it. I will now propose "That the Directors' report and statement of accounts for the past year be received and adopted."

Mr. JOHN TAYLOR seconded the motion.

A short discussion followed, and, in reply to questions,

The CHAIRMAN said, with regard to the selling price of the telephones, that he had known as much as £20 to be given. He did not think it would be wise to say what the Canadian Government would give. With respect to the amalgamation of the two companies in the River Plate, the opposition company was willing to amalgamate, but they wanted such high terms. He believed that the Chairman of the opposition company would be in London next month, and no doubt Mr. Taylor would see him and try and get better terms. As to raising the rates in that country, to compensate them for the fall in the exchange, that would be a dangerous proceeding, in view of the opposition. As a matter of fact, he would like to do so, and he would also like to raise the rates in Austria. He thought this was a question which must be left with the Board.

A SHAREHOLDER asked if the £214,000 in shares of subsidiary companies possessed any value?

The CHAIRMAN said he thought the question was an awkward one to answer. They could only judge what value these shares were by knowing that the Companies were every day improving in their business, and getting nearer to paying dividends.

A SHAREHOLDER: Are you open to a bid for them?

The CHAIRMAN: Yes. He then put the motion, and it was carried unanimously.

The retiring Directors, Major FitzGerald, Messrs. J. Taylor and R. Van-Zeller, were re-elected, as were also the auditors, Mr. J. G. Griffiths (Messrs. Deloitte, Dever, Griffiths, and Co.) and Mr. A. E. Green.

Mr. A. H. Baker (a Director) said, with regard to the question which had been asked as to the value of the shares held by the Company in the subsidiary companies, that if the business of those companies went on increasing in the same ratio as heretofore, they would not only be worth something, but something very considerable. If the subsidiary companies progressed as they had been doing, they would not only pay the charges, and the interest on the preference shares, but there would be something for the ordinary shares, on which this Company had put no value.

Mr. GRIFFITHS (one of the auditors), in reply to a question, stated that a charge of £1,500 was made against the profits last year in respect of the goodwill and patent rights. As a matter of fact, the patents were dying out every day, as all patents did, and though the goodwill might be improved, the auditors thought that some provision should be made for the patents for some years to come.

The CHAIRMAN, in further reply, pointed out that the amount standing in the balance sheet against good will and patent rights was £87,000, against which they held £214,000 in shares of other companies. If these shares were worth £87,000 they did not need to write off very much more from the value of the patent rights.

A vote of thanks to the Chairman and Directors "for their able and honest management of the Company's affairs" was then proposed and seconded, and

Mr. MASON, in support of the vote, said he thought the shareholders ought to know that the Chairman was at the factory every morning from eight to nine o'clock, looking over the correspondence, and giving the best attention to the Company's business, besides giving them a large amount of time during the day.

The CHAIRMAN, in reply to the vote, which was unanimously agreed to, assured the shareholders that the Directors would do all in their power to make the Company a success, and he thought they would do so.

The proceedings then terminated.

The South of England Telephone Company.

The first ordinary general meeting of this Company was held on Thursday, the 28th instant, at the City Terminus Hotel, Cannon-street, Mr. Robinson Kendal in the chair.

The SECRETARY (Mr. Fred. L. Robinson) having read the notice calling the meeting,

The CHAIRMAN said that the meeting had been called in conformity with the Companies Acts. It was what was called the statutory meeting, and it had to be held within four months of their incorporation. Practically there was no business to be brought before the shareholders, but as they had assembled together perhaps it would be as well that he should give them a few facts and figures in regard to their own Company in particular, and also in regard to the present position of telephony in this country. The Parliamentary Committee which had so exhaustively discussed the question of overhead wires had reported very favourably as to telephony—in fact, so favourably that he believed telephonic companies had

Digitized by Google

little or nothing to complain of in that respect. The local authorities and public bodies had hitherto placed serious obstacles in the way of telephonic enterprise, but after the exhaustive inquiry that had been carried on before the Parliamentary Committee he thought there was every reason to believe that those obstacles would be largely removed, and that in future they might look for a degree of tolerance, if not favour, from the public authorities throughout the country. The fetters and shackles with which telephonic enterprise had been bound since its introduction into this country by the Post Office authorities had now also largely disappeared, and practically telephone Companies had little or nothing to complain of compared with what they had twelve or eighteen months ago. As an instance of this, he might mention that he was in Cambridge the other day and had the honour and privilege of meeting the representatives of the two public bodies that governed that particular place, namely, the representatives of the Town Council and of the Improvement Commissioners, and after discussing the question of introducing the telephone into Cambridge, those bodies not only agreed to it, but warmly promised to give the Company every assistance in their power in introducing their system into the town. The same thing he might say had happened in regard to other places. At first, owing to the perversity of human nature, or to causes into which he need not now enter, whenever it was attempted to start a telephonic system in any town or city it was met with obstacles of one kind or another, and the local authorities almost uniformly cursed its introduction, but in the end it had been found in every case that what they began by cursing they ended by blessing. All the local authorities had been glad finally to adopt the telephone in connection with their fire brigade stations and other municipal institutions. Still, there was at this moment a vast degree of ignorance in regard to what the telephone really was. In a large town not many miles from London, where, a short time ago, they sent one of their local managers to open up a system, the head and chief local authority inquired whether their representative brought any testimonials showing what the telephone had done in other places or what it was supposed to do in connection with that town. The Company's representative said that he thought the telephone was known all over the world, but that local authority gave him to understand that they knew nothing about it. So much with regard to telephony in general. With regard to their own Company in particular he wished to give a few facts. As the shareholders all knew, they had a very large district, and that large district had, until their Company was formed, hardly been developed at all. The district worked by this Company comprised the counties of Northampton, Norfolk, Bedford, Cambridge, Huntingdon, Buckingham, Oxford, Berks., Suffolk, Sussex, and that portion of the counties of Kent, Essex, Surrey, and Hertford which was not included in the district of the United Telephone Company, which district comprised the county of Middlesex, and a radius of twelve miles from the General Post Office in London. The Company was only registered some three and a half months ago, and practically it was only six, or let him say seven, weeks since they had been actively at work in connection with the development of that district, and bringing their enterprise before the notice of the residents generally, and he ventured to think that during those six or seven weeks in which they had entered into their territory they had not allowed the grass to grow under their feet; but they had actively and zealously endeavoured to carry out the work committed to their charge. He saw no reason why their business should not be very larely developed, so that in fact the time might come when in every house of any consequence there should be means of communication by telephone with all the principal places in the neighbourhood. They had a tolerably large, successful, and improving exchange at Brighton. It had something like 200 members at the present time, and the number of subscribers to it was increasing daily, and he looked forward to the time when that exchange would be a very great success, and would, he thought, play a very important dividend-earning part in the affairs of the Company. They had exchanges also at Norwich and Ipswich. That day they opened one at Chatham and Rochester, which he thought promised to be one of the most successful exchanges in connection with their district. In five or six days they expected to open one at King's Lynn, and another at Hastings, while both at Reading and Northampton they had taken premises for an exchange. At Cambridge also they had secured suitable premises, and they hoped within eight or nine days to enter upon a very successful business in that town. They had been received very cordially by the Norwich municipal authorities and by the Improvement Commissioners, and he looked forward to the time when their system would extend over the whole town of Cambridge, where he believed they would have an opportunity of showing what could be done in the way of developing telephonic enterprise, as it might be shown in the internal arrangements of the different colleges and houses in the neighbourhood. Hitherto largely the telephone had been confined to the exchanges; but there was no reason why that should be so. There was, indeed, every reason, on the contrary, why the telephone system should be so developed that house and house, even dining room, bed room, and kitchen, should be connected just as completely as the exchanges now were. They had looked into the question of running different trunk lines, and they expected before long to make satisfactory arrangements for giving it a practical trial as soon as they had the requisite number of subscribers. They had made the necessary inquiries to see whether they could not run a trunk line between Chatham and London and other places, and he had no doubt they should be able to do it so profitably as to realise paying returns. Without taking into account any of the prospective business likely to accrue to them from the opening of the exchanges which he had named, their income from the orders they had on hand, executed and unexecuted, this month alone amounted to more than £750, which, he thought, considering that they had been practically in existence only for six or seven weeks, was very satisfactory indeed. There was no reason why this income should not increase month by month. If it did not do so he thought he might promise them on behalf of his colleagues, and he certainly spoke for himself, that it would not be through any fault of theirs. The telephone ought to progress and develop, and if it did not the fault would be the fault of the people on his side of table. They had made arrangements calculated to develop the business over that larger district. They had engaged a number of active, zealous, and experienced young men, whom they had sent at no great cost to their district, and they thought with the assistance of those young men, who would be watched and encouraged, they would be able to increase their business and produce a satisfactory result at the end of the year. They had no drones on their staff, nor any sinecure in their service, and when they took these facts into consideration, he thought the shareholders might rely on this, that, when they met to receive their first balance sheet, they would have no cause to regret having committed their interest to the care of the present Board, who, they would see, had endeavoured as far as in them lay to develop telephonic enterprise.

Mr. BEAVIS asked how many towns were connected with London by trunk lines.

The CHAIRMAN replied that at the present time they were only connected with Brighton, but they had it in contemplation to connect Reading, Chatham, and Rochester. They did not intend to commit themselves to any undertaking, unless they could get a guaranteed number of subscribers to make it a sure paying and successful operation. In further answer to the same gentleman the Chairman said that the Company had quite sufficient money for carrying on their business. They had £30,000, and he did not think they would require any more for a considerable period.

A vote of thanks having been accorded to Mr. Kendal for presiding, the proceedings terminated.

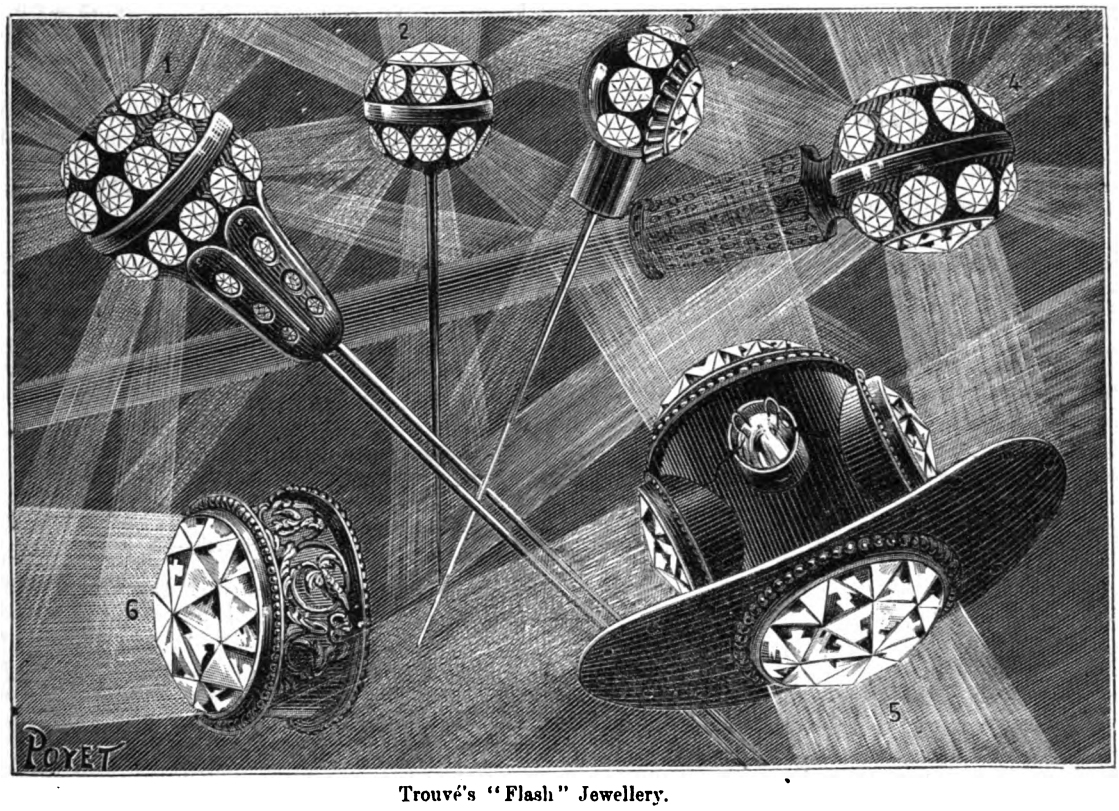
THE INTERNATIONAL INVENTIONS EXHIBITION.

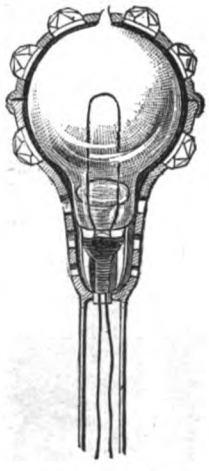
The same remark with which we previously commenced applies still—progress is very slow. The chaos in the machine room is, however, gradually giving place to order, and the visitor is able to gain a somewhat better idea of what it will be like when completed than he was two weeks ago. It will easily be understood, however, that systematic arrangements for describing the exhibits are altogether impossible. Workmen here, workmen there, workmen everywhere, create a scene of confusion which prevents the tracing of circuits, or of careful investigation in any shape. One conspicuous weak point is in the lighting of the arcade devoted to Group XIII—the electrical exhibits. Naturally we look for the acme of electric lighting, and are met with nothing but oil lamps. However, it may be that by the time the goddess of the weather has decided to give us warm bright evenings the Exhibition will be practically perfect. We may take this opportunity of stating that we have arranged for a more scientific investigation into the merits and demerits of the dynamos and motors, independent altogether from the merely descriptive report of the exhibits. We hold that the interests of our readers will be best served by such a course. The illustrated descriptive matter may be looked upon as food for babes, the critical matter for the sustenance of those who have passed out of the weakling into the youthful or even maturer stages. While exhibitions follow so closely upon one another the casual investigator fails to see the progress made; to him the Siemens, Crompton, Brush, Gramme, or other machine is still the same. The change of weight in the field-magnet cores, the change in the winding of field-magnet or armature, the detailed alterations in brushes and other parts fail to rivet attention, because on the whole the "type" of construction remains the same. But the constructor knows that every change of screw or material has been made with a definite object, and that after trial the object for which the alteration was made has been partially or wholly attained, otherwise the old form would remain. It must not be expected that these minor alterations always or even frequently have for their object electrical improvements; they may, and many have, an objective in the simplification of the arrangement, or in improved construction. To those who desire to obtain a thorough knowledge of what has been done during the past six or seven years we suggest not only a careful investigation of the forms of to-day, but also a careful comparison of these with the forms that are now looked upon as obsolete. Our object, however, is description, not sermonising. Then, again, wending our way to Group XIII. in the East Arcade, let us commence by directing attention to the exhibit of M. Trouvé, one of those exhibits which can be looked upon as complete. So much has been said of M. Trouvé's work, and the greater portion of these exhibits have been so often described and illustrated, that our work is of the simplest. The study of economic science shows us that a large part of the human race has to be satisfied if it can obtain necessaries, while another part can revel in luxuries. Many of M. Trouvé's exhibits partake of the luxurious, in that they show how the electric light lends itself to artistic decoration. We do not know whether the flash jewellery so largely used for theatrical effects is to be classed as luxurious and decorative, but we do know that M. Trouvé has a large number of specimens of this kind of jewellery. Briefly, for the sake of the younger readers, we may say that M. Trouvé was, so far as practical purposes are concerned, the original investigator into the possibilities of a secondary battery. His investigations have led him to devise various forms of secondary batteries and incandescent lamps for mining and other purposes. The original form of Trouvé battery was simply opposed plates of lead rendered porous by continued charging and discharging, so as to obtain large surfaces for the storing up of electrical energy. During the period of charge one plate is chemically acted on to form peroxide of lead. If a plate so peroxidised is placed in a cell containing dilute sulphuric acid opposite to a plate of pure lead, and the two plates are joined by means of a wire like any other voltaic cell, a current passes through the wire, as long as any peroxide remains unreduced. In *The Electrician*, Vol. XIV., page 26, will be found various illustrations of portable lighting apparatus, consisting of Trouvé batteries and incandescent lamps intended primarily for mining purposes; while in the same volume, p. 128, are illustrations of other forms to be used for



Trouvé's "Flash" Jewellery.

Digitized by Google

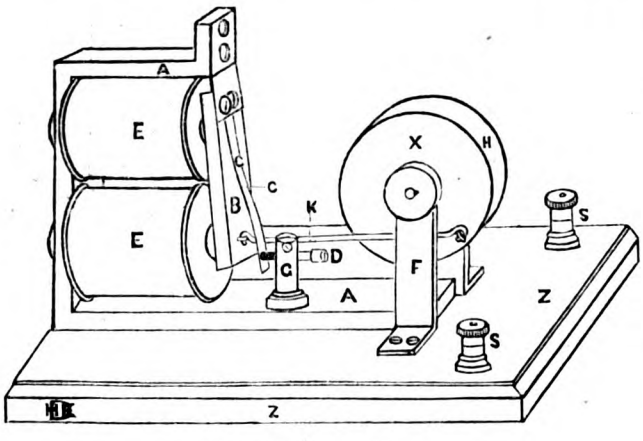
various purposes, such as investigating gas pipes in long tunnels, or in fact wherever a gas escape is suspected; for lighting gas lamps; for carriage lamps, &c. Passing once more from the grave to the gay, we repeat our illustration of "flash" jewellery, to give some idea of what may be seen in M. Trouvé's exhibit. The smaller illustration shows how the light is arranged, a small lamp of one or two candle-power inside surrounded by glass facets for the purpose of directing the rays. We have no doubt that this exhibit will prove the most interesting in the arcade, so far as ladies are concerned,



Trouvé's Electric Pin.

although many may prefer the style of decorations shown by Mr. Swan.

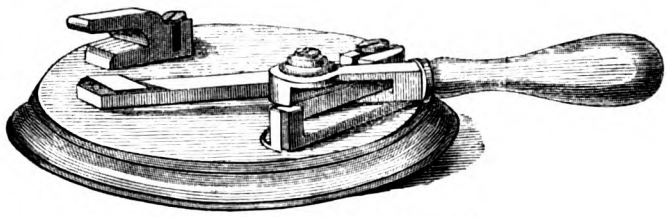
A new patent electric clutch motor is exhibited by Messrs. Bayley and Son, of Poole, Dorset. This is arranged to be entirely self-starting at full power, in any position, and to be self-regulating. The chief faults of small electro-motors hitherto have been that they would not start themselves, and that however effectual they might be when running at a high speed, when that speed was reduced not only was the power reduced but the current required was increased. The subject of our illustration, however, is said to possess neither of these faults; it is self-starting in any position, it regulates its length of stroke according to the work to be done, its highest speed is only about 200 or 300 revolutions per minute, and its "pull"



Bayley's Clutch Motor.

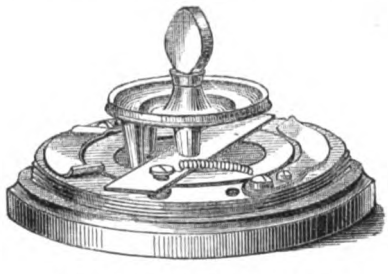
is very great. For example, a pulley was fixed to the spindle of a Griscom motor, weighing 2½lb. On connecting it with a battery of six good sized bichromate cells a weight of 3oz. was drawn slowly up; on connecting the same pulley and battery to one of these clutch motors, having four times the resistance and weighing 2lb., a weight of 30oz., was lifted. The motor consists of an electro-magnet, E, in front of whose poles is an armature, B. This armature is provided with a contact spring, C, and contact breaker, G, so that as the current passes the magnet may be alternately magnetised and demagnetised. A second magnet, H, is provided, mounted upon an axis, which axis may be in any position, and this magnet, with its axis, is free to revolve. In front of the poles of this second magnet there is a loose disc armature, X. This loose armature is attached by a rod, K, to the vibrating armature B of the electro magnet E. The current passes entirely through both magnets, when immediately the armature B is attracted to the poles of E, and the loose disc X is also drawn by reason of its attachment to B; but as at the same time the electro-magnet H is excited, it clutches or holds the disc X, and is carried round a slight distance with the disc. The spring C then breaking contact, both magnets become demagnetised, and the armature B falls back, the disc returning to its former position. Contact is again made, and the same routine of operation proceeds. Thus the axis, with its magnet and pulley, revolves by reason of a rapid succession of reciprocating motions, which are converted into a continuous and uniform rotary motion, whether the load is on or off. A is an iron frame to which the magnet E is secured, F the brass bearings of the axis and clutch magnets, S S the terminals for attaching the battery wires, and Z Z the polished mahogany base board. For working as an electric bell a cam is placed upon the axis, which at every revolution acts on the spring arm of the hammer, and causes the bell to sound with great power. By providing suitable gearing the rotary motion can readily be transmitted. As to the power required, it is said to be very small, the comparatively large power of the motor being due to the short direct attraction of the armature by the electro-magnet and to the minimum of friction loss which has been arrived at.

Messrs. J. H. Holmes and Co. (Stand 1,375) show a variety of electrical fittings. Of switches, cut-outs, &c., we may say their number is legion, and certainly much study of them would be wearisome. The pioneer in cut-outs, Mr. Killing-



Holmes' Switch—Single Contact.

worth Hedges, is represented elsewhere, but almost every electric light engineer is getting out his own design of switch and cut-out. The exhibit of Messrs. Holmes and Co. needs little description. The type of switch will be seen from the illustrations given. Of course the designer claims that his switches prevent the formation of a destructive arc when the



Holmes' Switch—Duplex Contact.

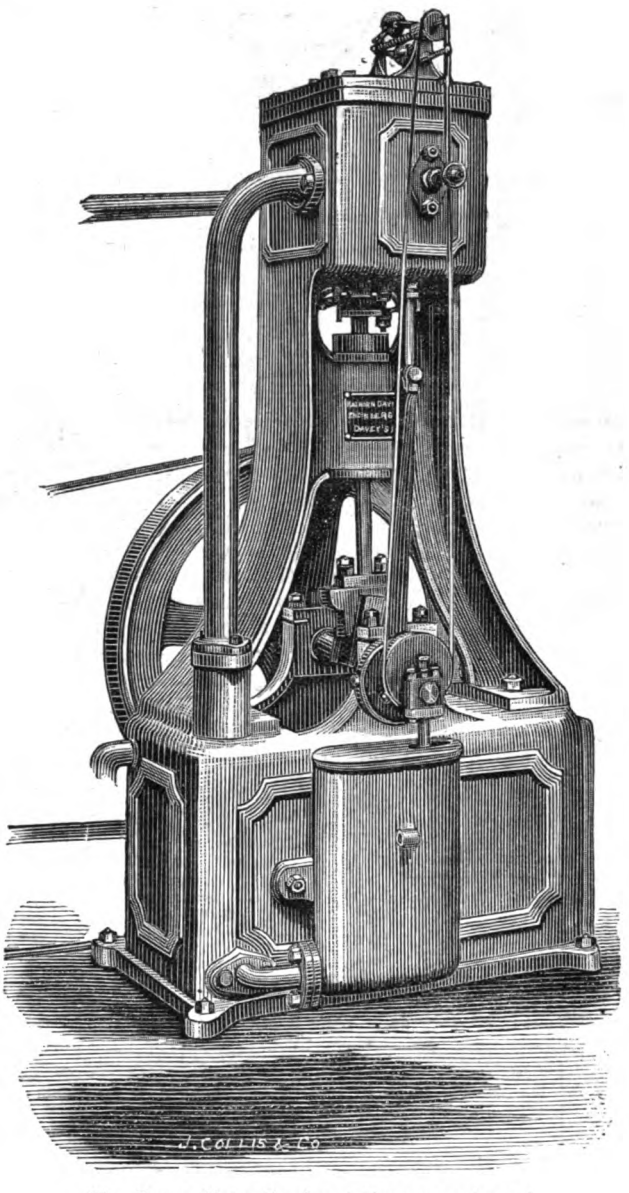
current is broken, have the surfaces kept clean, and good contact ensured by their coming together with a rubbing motion. In these switches the contact piece is made independent of the handle, so that on breaking contact it may fly back suddenly under the influence of a spring only, and out of the control of the operator. The contact, therefore, is broken so quickly that the spark is not of sufficient duration to cause any damage. The spring is arranged to keep the movable contact piece in the "off" position, but on turning the handle to complete the circuit

Digitized by Google

the contact piece is moved in opposition to the pressure of the spring and is kept in the "on" position by being forced between the fixed jaws and held there by friction. The handle may traverse about 30° without moving the contact piece, always pushing the bar before it when making or breaking contact. On turning the handle to break circuit its first action is to release the contact bar from its frictional hold, allowing it to dart away suddenly under the influence of the spring, thus breaking the circuit so quickly that a dangerous arc cannot be formed. These switches are made in a variety of patterns on either wood or slate bases, and with terminals either on the face of the block, or below, so that in the latter case switch-boards may be arranged to look as neat in appearance as possible.

We may be permitted to digress from Group XIII. to Group II. in the South Gallery. Passing from the machine room to the East Arcade, we have often watched at work the little model machine shown by Messrs. Ernest Scott and Co. This machine is intended to separate iron from other substances. From the following description it will be seen that the separation can only be effected when the other substances are not attracted by magnets. To show the working, the mixed material is fed into a hopper marked "Iron, brass, and refuse," from which it falls upon the nearest of the two endless belts, and is taken under a rotating disc carrying electro-magnets. This disc is carried upon a spindle, the upper portion of which revolves against a commutator, so arranged that contact is made as each section of magnets comes over the nearest belt, and broken as it arrives over the other one. It therefore follows that the electro-magnets pick up iron from one belt, and when over the other drop it, having, by the cessation of the current, ceased to be magnetic. By this means the iron is collected in one hopper, and the material from which it has been extracted in another. Many previous attempts, say the inventors, have been made to utilise magnetism for the separation of iron from other substances with which it may be mixed, but they have all failed to accomplish any great amount of useful work. When permanent magnets have been used, as in the well-known "magnetting machines," the amount of material treated in a day is very small, as the iron has to be removed by mechanical means, and the magnets are brought into direct contact with the substance treated, which accounts for the comparative slowness of the process, and also for the fact that the compounds with which the metal is mixed cling to the particles of iron, and are thus taken out at the same time; while, in the electro-magnetic machines previously patented and suggested, no really efficient or adequate means have been provided for removing the iron from the magnets.

In our issue of November 1, 1884, we described and fully illustrated the exhibits of the Pilsen Company at the Healtheries. The company has an exhibit of a similar character at the Inventions, so that having so recently referred to the apparatus we shall content ourselves with a shorter reference. The dynamo-electric machines are of the Schuckert type. The exhibits are arranged to show clearly the nature of these modifications introduced by the company, and the advantages to which they have led. Four machines are used to maintain the arc lamps, three being in actual use, one kept as a reserve. The core of the armature is of soft hoop iron wound up tightly in volute form. The layers of iron are separated one from another by strips of calico or longcloth wound in with the iron; a sufficient number of turns is given to form the broad flat ring characteristic of the Schuckert type, and the sections of wire are then wound upon it. The central boss carries a number of radiating arms terminating in a kind of fork, into which the hoop-iron is wound directly. This method of mounting the armature allows the latter to be built up of large diameter. The sections of wire on this ring in some of the company's dynamos are separated one from another at the periphery by soft iron shoes or wedges insulated from the rest of the iron in the core. It is claimed for these separate pieces that they increase the efficiency of the machine. At the Exhibition two of the machines maintain 14 arc lamps each through about 400 yards of wire leads, at a speed of 775 revolutions a minute. Each of the remaining two, having more wire on the armature, maintains 14 arc lamps through about 400 yards of leads, at a speed of 614 revolutions. The current meter, of which there is one on each circuit, has the form of an ordinary flat-coil galvanometer, the directive action of whose coils is intensified by the introduction of soft-iron cores. Between the poles of this electro-magnet rotates a soft iron armature against the tension of a spiral spring. This armature carries an indicator needle, which moves over a graduated dial. The shape given to the poles of the electro-magnets produces equal deflections for equal increments of current. The readings are constant, and the armature is sensitive to extremely small variations of current.



The Davey Motor (for description see next page).

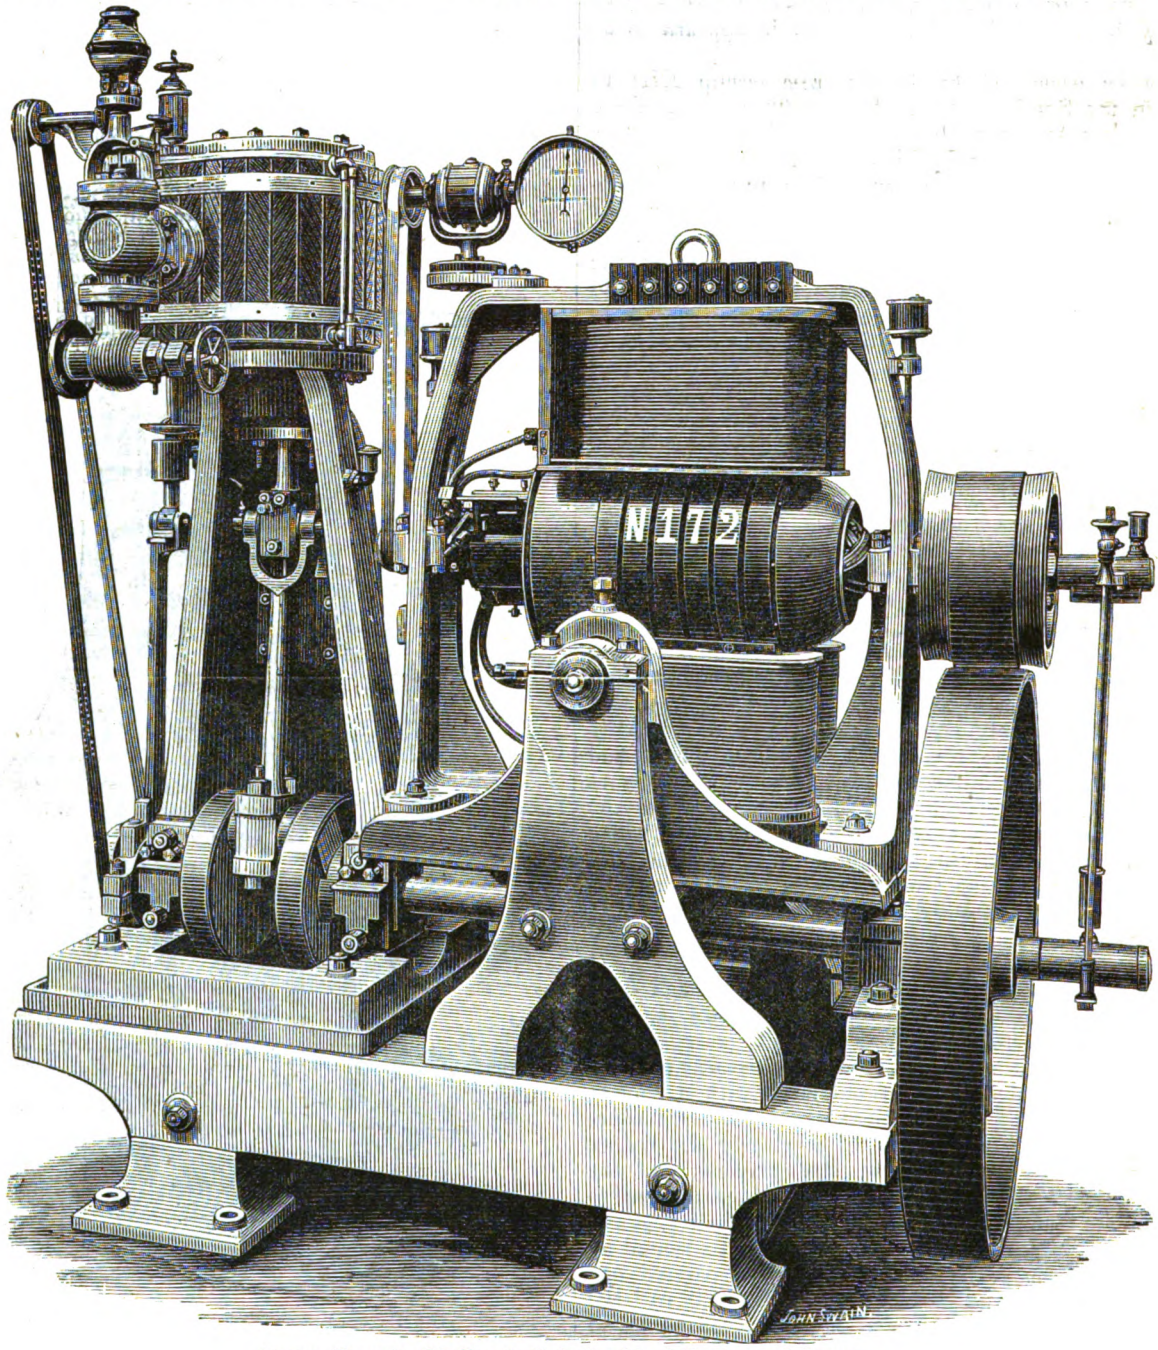
The West Gallery, in which are the principal exhibits of machinery in motion, is lighted by Pilsen arc lamps. These are of the common type known as P^1, the characteristic features of which are the biconical solenoid core and tandem coils. Near the machines are exhibited other types known as P^3, having two conical cores and parallel coils; P^5, having tandem coils placed horizontally; and P^2, which is the latest development. In this lamp there is but one spool, on which are wound both the main and the shunt coils, within which moves a single tapered core. It is claimed for this lamp that it possesses the steadiness of feed distinctive of the other

Digitized by Google

types of Pilsen lamps, while its moving parts are so few that derangement is, with reasonable care, hardly possible.

In a preceding notice we mentioned that two of the Davey motors, as described in *The Electrician*, March 14th, this year were at work in the engine shed. By the side of the magnificent engines of Messrs. Davey, Paxman, and Co., these little motors appear as pigmies, yet they will be found to have their uses. The illustration on preceding page shows the engine at the Inventories which differs but slightly from that given in our previous description. The engine is double-acting, and supplied with steam at or about the atmospheric pressure subsequently condensed. The vacuum obtained The vacuum obtained in the condenser is 25 to 26in., and an experiment was made to show the degree of vacuum required to overcome the friction of the engine and resistance of the air-pump, with the result that, with a condenser vacuum only 5in. of mercury lower than the boiler pressure, the engine ran at its normal speed. As, under ordinary working conditions, the difference between the boiler and condenser pressures is about 25in. of mercury, there is an available margin of 20in. of mercury, or say 10lb. per square inch above that required to overcome the friction of the engine. This shows an efficiency of 80 per cent, not a bad result; and, working at atmospheric pressure, the Davey motor is no more liable to burst than a tea-kettle, while, as the boiler is self-feeding and the fire can be made up to last for a long time, the least possible attention is required.

Messrs. Browett, Lindley, and Co., late Deacon and Parker, show a vertical compound engine, and an engine and dynamo combined, which we now illustrate. The engine has a 6in. cylinder and 8in. stroke. The dynamo is mounted on a swinging frame. The heaviest end of this is next the fly-wheel of the engine, and is supported by the pulley of the dynamo resting on the fly-wheel. The pulley consists of discs of paper compressed between two iron discs, and is caused to revolve at 800 revolutions per minute, while the engine makes about 150. In order to increase the adhesion there are two light rods, as shown, which unite two brass bearings, one on the dynamo spindle and the other on the crank shaft, and by turning two hand nuts screwed on the rods, the pulley can be forced down on the wheel and thus more adhesion obtained. This arrangement seems to run very well; but its value will be better understood at the close of the Exhibition, by which time it will have undergone a pretty severe test.



Messrs. Browett, Lindley & Co.'s Combined Engine and Dynamo.

NOTES.

NEW AMERICAN COMPANY.—The North Western Electric Company has been incorporated at St. Paul, Minn.

ANOTHER ELECTRICAL EXHIBITION. — An International Electrical Exhibition is to be held in Milan in 1887.

MANUFACTURE OF ACCUMULATORS.—M. Epstein, of Leipzig, is about to transfer his manufacturing business to Berlin.

ELECTRIC LIGHTING OF A TOWN.—It is announced that the town of Saint-Jean-de-Maurienne (Savoie) is about to be electrically lighted.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 29th May amounted to £2,971.

THE TELEPHONE IN PARIS.—The telephone did good service in Paris the other day, on the occasion of an extensive fire in the Rue Michel-le-Comte.

ELECTRIC CLOCKS.—More than 700 electric clocks have already been installed in different parts of New York, and the demand for them is increasing rapidly.

THE EARTHQUAKE AT CASHMERE.—A despatch from the British Resident in Cashmere states that no Europeans were killed during the recent earthquake shocks.

NEW ELECTRICAL METER. — A new meter has been patented in Spain by D. Felipe Saldaña. Our contemporary, *La Gaceta Industrial*, is enthusiastic in its praise.

OBITUARY.—The death is announced at Berne on the 13th ultimo of M. Albert du Faure de St. Martial, Secrétaire du Bureau International des Administrations Telegraphiques.

THE DAFT MOTORS.—The Daft Electric Light Company are building some motors for testing the merits of their invention in a practical manner on some of the American railroads.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of May, 1885, were £1,345, against £1,552 in the corresponding period of last year.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 31st May are £3,813, as compared with £3,245 in the corresponding period of 1884.

THE ELECTRIC LIGHT FOR A CASINO.—The Casino at Aix-les-Bains (Savoie) is about to receive an installation of 20 Jablochkoff lamps, 14 regulators of a new kind, and about 60 Woodhouse and Rawson incandescent lamps.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May amounted to £50,016, and to £41,708 in the corresponding period of 1884; increase, £8,308.

THE ELECTRIC LIGHT IN BARCELONA.—The cavalry barracks situated at Barceloneta, a suburb of Barcelona, is about to receive an installation of powerful arc lights. The Sociedad Espanola de Electricidad have charge of the work.

CIVILISING THE AMEER.—Complete apparatus for lighting the Ameer's palace by electricity has been despatched from Bombay to Cabul. The electric light took his Highness's fancy at Rawul Pindi, and he resolved to introduce it at home.

NOTICE OF INTERRUPTION.—The Eastern Telegraph Company notify the interruption of their duplicate Aden-Bombay cables. Until they are repaired telegrams for India, China, &c., should be sent through the Indo-European Telegraph Company.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 29th May, 1885, were £2,346, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

ELECTRICAL FITTINGS FOR THE ADMIRALTY.—We understand that the tender of Messrs. Goolden and Trotter, of 2, Victoria-mansions, Westminster, has been accepted for over 11,000 electrical fittings, of which a considerable quantity have already been delivered.

THE GLAESENER SECONDARY BATTERY.—We have to acknowledge the receipt of a cell and some specimens of electrodes, &c., from Glaesener Freres, of Chatillon (Luxembourg, Belge). We propose to thoroughly test this cell before entering into any discussion as to its merits or demerits.

STRUCK BY LIGHTNING.—A telegram from Calcutta states that a terrific storm raged at Hyderabad on Thursday last. The mess room of the 14th Hussars was struck by lightning while the officers were at mess, and two of them, Lieutenants Seymour and Bentley-Innes, were killed instantaneously.

THE EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1885, amounted to £61,327, and to £51,537 in the corresponding period of 1884. The exceptionally large receipts were caused by the Afghan frontier dispute, hostilities in the Soudan, and settlement of the war between France and China.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this Company during the month of May was 4,474, estimated to produce £3,700, against 3,339 messages, producing £2,973 in the corresponding month of last year. The traffic receipts for the month of February, estimated at £2,700, realised £2,730.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—An extraordinary meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, Westminster, on Thursday, 13th June, at eight p.m., when a paper will be read "On the Calculation of Mains for the Distribution of Electricity," by W. H. Snell, associate.

THE "MAGNETA."—Mr. Commissioner Rothery held an inquiry on Wednesday last at the Sessions House, Westminster, into the loss of the "Magneta," which left London on March 8 with fifty-four hands on board, and which since the 10th of that month has not been heard of. The accounts of the pilots who were in charge of the vessel from Glasgow to London and London to Portland are that her behaviour was very satisfactory.

A THERMIC MOTOR.—For the past few months the Triple Thermic Motor Company has had under construction in Lowell, Mass., an engine proposed to be devoted to the use of the Middlesex Electric Light Company of Lowell. The engine was started at the works in Jackson-street on 6th May, and has given excellent results. It is said that all the dynamos of the Middlesex Electric Light Company will be transferred to the building at an early date.

ON THE MEASUREMENT OF MAGNETIC FORCES BY HYDROSTATIC PRESSURE.—Prof. G. Quincke adopts the formula

$$p = \mathfrak{A}_1 H_1^2 / 8\pi$$

where H_1 is the intensity of the magnetic field, and $\mathfrak{A}_1$ a "dimagnetisation constant" analogous to the dielectric constant in the analogous formula for the pressure in the electric field. Observations have been made on many magnetic liquids to ascertain the numerical values of this constant.

Digitized by Google

THE POST OFFICE TELEGRAPHS.—According to a contemporary the increase of telegraphic business has been amazing. In 1871 the number of telegrams in the provinces was 5,300,000, and in London 2,900,000; in Scotland about 1,000,000, and in Ireland 606,000. But in 1883-84 the provinces sent 15,000,000, London 12,700,000, Scotland 3,300,000, and Ireland 2,000,000, making a total of 32,000,000, as against the 9,000,000 of 1871. The number was still increasing at the rate of about 2½ per cent. per year.

THE NATIONAL TELEPHONE COMPANY.—The list of subscribers in the Scottish North-Central District for the past month shows that this company is making satisfactory progress. The first telephone was not introduced into Dundee until 1879, and there are now in operation 915 telephones and 628 miles of wire in the district. The lines are operated upon Mann's circuit line system, which is said to possess in point of convenience many advantages over the systems adopted by other telephone companies.

WIRES COMMITTEE IN FRANCE.—The following gentlemen have been nominated members of the special commission appointed to consider the question of the proper and safe conveyance of high tension currents of electricity in France for electric lighting and other purposes:—MM. Baïhaut, député; Krebs, capitaine adjudant-major au régiment des sapeurs-pompiers; Fribourg, directeur du personnel, chargé de la direction du service central au ministère des postes et télégraphes; Brunot, chef de cabinet du ministre des postes et télégraphes.

THE TELEGRAPH IN THE FAR EAST.—With regard to the proposed telegraph between Hong Kong and Singapore Sir George Bowen, at a meeting of the Hong Kong Legislature, announced that the Eastern Extension Telegraph Company would require a guarantee of £20,000 a year for twenty years before undertaking to lay a direct cable. There is, therefore, no prospect at present of the scheme being carried out, especially as both the Legislatures of Hong Kong and Singapore agree that the present condition of their revenues does not allow them to offer any substantial aid to the project.

UNFORTUNATE.—The telephone is an admirable institution, more especially in America, but the too frequent use of the instrument sometimes leads to awkward mistakes. An old lady who happened to be deaf went into a linendrapers the other day and adjusted her ear-trumpet preparatory to commencing negotiations. Unfortunately for himself and his employer, an absent-minded shopman sent a stentorian "Hello" with such force against the old lady's tympanum that she flounced out of the shop without giving the science-stricken server of ribbons time to recover himself.

THE OBSERVATION OF EARTH MOVEMENTS.—Our contemporary, the *Science Monthly*, contains a very interesting account of some observations of earth-movements in Italy. For manifesting the noises and rumblings of the earth's crust a microphone was buried at a depth of five or six yards, in a retired and quiet situation. Small rods of metal were found preferable to carbon. A copper needle was balanced on a pivot, with its extremity resting on a bit of platinum. When a resonator was adapted to the receiver, the noise became strong enough to be heard in an adjacent room. Electrical apparatus was also used for registering the upheaval jerks and undulations of the earth.

LONG-DISTANCE TELEPHONING IN THE WEST INDIES.—Our contemporary *The Colonies and India* says:—By a simple connection of the telegraph wire to the telephone instrument in the News Room at Port of Spain, it was found that communication with San Fernando, a distance of 45 miles by wire, could be carried on with as much ease and precision as between any two places in the city. Remarking upon this achievement, the *Gazette* says:—"The day may not be far off when telephone subscribers will be able to converse between both towns, and to the police service such an acquisition would prove an immense boon. Several gentlemen conversed with Mr. Hodges, the telephone manager, at the other end of the line.

THE TELEPHONE IN THE WEST INDIES.—In 1882 the Tropical American Telephone Company started two exchanges in the West Indies, one at Barbadoes, and later one at Trinidad. The former was sold to local capitalists, who organised the Barbadoes Telephone Company. After reaching 140 subscribers at Trinidad the company encountered competition, a rival system, using M'Donough telephones, being started. The company reduced its rates, registered its English patents on the Bell and Blake instruments, and the opposition ceased. Trinidad merchants have now purchased the company's plant and property and are developing the business. There are now 200 sets of instruments at Barbadoes and 250 sets at Trinidad.

UNDERGROUND ELECTRICAL CONDUITS.—According to our contemporary the *Scientific American*, the Electric Underground Conduit Company have recently exhibited a new system of conduits in which each wire passes through a separate paper tube ¼in. in diameter. This tubing is surrounded by double layers of silvered paper to prevent interference from induction and supported by perforated partitions in wooden boxes. The surrounding space is filled with an insulating asphaltum compound. Each wire terminates at the stations in a separate binding screw, thus forming an independent connection throughout the entire system. This construction presents a decided advantage in case of accident, or where several companies use the same conduit.

THE FUNERAL OF VICTOR HUGO.—A contemporary says:—"In order to ensure the completion of the colossal Cenotaph, and of the fitting up of the Arc de Triomphe by Sunday morning, the men are now (Friday) working all night by the electric light, which has been temporarily installed. During the whole of last night the progress of the work was watched by crowds of people. In the blaze of the electric light the effect of the immense wooden structure, already partly covered with its sable draperies, against the massive proportions of the Arc de Triomphe was very remarkable; and the strangeness of the scene was increased by the ordinary street lamps all round the place being covered with crape and decorated with sheaves of bannerets."

THE ELECTRIC LIGHT IN MADRID.—The installation at the Teatro Real consists of 250 Siemens and Halske incandescent lamps of 25 candle-power each, 400 accumulators, and six Gramme dynamos, type A. The cost of the installation is said to be as follows:—

Steam motor of 14 horse-power	£290	12	6
Six Gramme dynamos (1 spare)	279	0	0
Shafting, &c.	27	2	4
400 accumulators	620	0	0
250 lamps	72	5	2
Cables	193	15	0
Cost of labour, &c.	193	15	0
Sundries	77	10	0
Total	1,754	0	0

The daily cost of the light as compared with gas is, taking it altogether, slightly in favour of the new illuminant.

Digitized by Google

THE BELLE SAUVAGE PRESS.—From a small and beautifully illustrated pamphlet descriptive of the exhibits of Messrs. Cassell and Co., at the Inventions Exhibition we extract the following account of the electrotyping process as carried out by them :—"The type formes and woodcuts are delivered from the composing room to the moulding room, where wax impressions of each page are taken. These are placed in huge troughs, and subjected to electric action by means of a power-driven dynamo machine, similar to those used for producing the electric light. By this agency a coating of copper is deposited upon the mould, and a fac-simile of the page of type or woodcut is produced. This is 'backed up,' turned, planed, and otherwise finished in another room; then, after being examined, it is transferred to the imposing room, where all the plates are mounted upon metal blocks ready for the printer."

ELECTRIC LIGHT PATENTS.—Suits were begun recently in the United States Circuit Court by the Edison Electric Light Company against several companies which manufacture incandescent electric lamps and against the users of lamps made by these companies. The alleged infringers, against whom suits were begun, are the United States Electric Lighting Company, the United States Illuminating Company, the Consolidated Electric Light Company, and the Swan Incandescent Electric Light Company. The Remington Electric Light Company and the Schuyler Electric Light Company are also said to be among the companies against which actions are to be begun. The Edison Company asserts that its patents cover the incandescent lamp, the methods of manufacturing the lamp and lamp-sockets, fixtures for carrying lamps and sockets, construction of dynamos, &c. The amount of invested capital that will be affected by these suits is estimated at £3,000,000.

"DAS TELEPHON."—The following lucid and expressive little poem appears in a recent issue of our American contemporary, the *Electrical World*:—

Viele Wörter gibt es schon
Auf gut Deutsch fuer "Telephon":
Fernhinsprecher, Weithersänger,
Surrschnur, Säusler, Schallempfänger,
Plapperfaden, Wortaustauscher,
Sprechdraht, Klangstrick, Weithinlauscher,
Ohrverläng'rer, Antwortbringer,
Hausspion, Luftwellenklinger,
Weitschwatz, Kilometerzunge,
Stubenhorcher, Meilenlunge,
Sprechwerkzeug, Besuchersparer,
Tonrohr, muendlicher Verfahrer,
Doppelstahlblechzungenreger,
Klangverbreiter, Blitzwortträger,
Sprechpostschalter, Musikleiter,
Schallmaschine und so weiter.

A CLOCK ELECTRICALLY LIGHTED.—At the General Post Office, Melbourne, Victoria, the upper portion of the clock tower will be taken down, and it will then be raised till its total height reaches 188ft.; the present illuminated dials, which are too small to be of any practical use, will be dispensed with, and four new skeleton dials, each about 13½ft. diameter, will be provided, the centre of the dials being about 132ft. from the ground. A new feature will be introduced in connection with these dials; they will be made of cast iron, and will have hemispherical recesses so spaced as to mark the hours in place of the usual numerals; these will be nickel-plated inside so as to reflect the sunlight and form bright points in the daytime, and in these cups incandescent electric lights will be placed, while similar lights of smaller size will be arranged in a close row along each of the hands. It is anticipated that this arrangement will make it possible at night to tell the time by this clock at a great distance.

SUNDRY INSTALLATIONS ON THE CONTINENT.—At Dresden the Lesigke Restaurant has 30 Bernstein incandescent lamps, and the Theatre Royal 220 Edisons. At Munster 1,000 lamps light the clothing establishment of M. Hartmann. The stations, the workshops, the theatres, have all adopted the same means of illumination. There are 19 sugar manufactories possessing in all 3,300 incandescent and 42 arc lamps. The most important is that of Frellsteds with 600 lamps and 12 regulators. Four clothing establishments at Brunn have 700 Edison lamps. Kiel also possesses several installations, and the little town of Triberg is about to be similarly favoured. Amongst the installations which have lately been put down in Berlin we may mention that at the Hotel Central, carried out by Messrs. Siemens and Halske. This comprises a 40 horse-power steam engine, driving nine dynamos, each of which furnishes the current for five or six arc lamps, 37 regulators distributed through the hotel and gardens, and a number of incandescent lamps in the offices and private apartments.

THE ELECTRIC LIGHTING TESTS.—Some further details of the tests conducted at Philadelphia by the Franklin Institute, which have recently come to hand, show that as a result of 600 hours' continuous lighting, that of the 20 lamps submitted by the United States Company 12 have gone out; the Stanley Company have lost 16 out of their 20; the Woodhouse and Rawson Company have lost 9 out of their 10; and the Edison Company 1 out of their 20. All have lost some candle-power, some more than others, but no accurate statement could be had as to the efficiency—*i.e.*, the current necessary to send through each lamp. It was found that the Weston (U.S. Co.'s) lights required 3·6 watts per candle, the Edison 4·4, the Stanley 4, and the Woodhouse and Rawson 3·8. As to the dynamo test, which will begin in about two weeks, great care is exercised in the preparations. Only six dynamos are now in the building for testing, three of the Edison and three of the Weston pattern, but more are expected. The tests will not be finished before the middle of June.

THE LANCASHIRE AND CHESHIRE TELEPHONE EXCHANGE COMPANY.—From the list of subscribers for May in Manchester, Manchester sub-district, North Lancashire, and Liverpool sub-district, we note that this company have already joined up the undermentioned places by trunk wires, and that they purpose extending the list as rapidly as circumstances permit:—Accrington, Ashton-under-Lyne, Blackburn, Blackpool, Bolton, Burnley, Bury, Darwen, Heywood, Liverpool (including Bootle, Garston, Gateacre, Old Swan, Waterloo, and Wavertree), Manchester, Middleton, Oldham (including Hollinwood, Royton, and Shaw), Preston, Radcliffe, Rochdale, Runcorn, St. Helens, Stalybridge, Stockport, Warrington, Widnes, and Wigan. In the public call stations any one may converse by telephone, not only with subscribers to the company's exchanges, but also with anybody who, by previous appointment between the parties concerned, has gone to some other call station to receive a message. This feature will, no doubt, prove a great convenience to those who are not subscribers to the company's exchange system.

THE "MOLECULAR" TELEPHONE.—In the so-called molecular telephone of Messrs. Waite and Bartlett the receiver consists of a magnet bent into a semi-circular shape, with a re-entering end, to which is secured a soft iron core. To the side of the case there is secured an iron spring, which bears upon the diaphragm, and can be regulated by a screw. The

Digitized by Google

diaphragm is made of wood, cork, cardboard, or other non-magnetic material. Thus the varying currents over the line cause vibration in the spring, which vibration is in turn communicated to the diaphragm. The transmitter employed by the inventors is a modification of the Hughes microphone. Mounted on a sheet of cork are six rods of carbon with reduced ends, the inner one of which fits loosely into holes in a central carbon button. Their outer ends are also supported by smaller buttons, connected up in two series of three in parallel. In the latest form of this transmitter the buttons are clasped by brass springs which encircle them, permitting of easy adjustment, and removable in case of breakage or repair. The articulation of this telephone is said to be very distinct, and inductive effects are considerably reduced in intensity.

NICKEL.—In the *Centralblatt fur Electrotechnicker*, Dr. Böttcher lately called attention to the valuable chemical properties of nickel, as well as its resistance to oxidation—even in damp air—and likewise to acids. When once dissolved it is only with great difficulty separated from its combinations. Regarding its electro-chemical properties, it is asserted that it does not precipitate copper from solutions of blue vitriol, and when joined with copper in these solutions gives no current, while the combination heat of copper with sulphuric acid is only 29,500 calories. Even with platinum nickel gives no current in sulphuric or hydrochloric acid. For the definition of the electro-chemical equivalent of nickel in combinations with sulphuric acid, nickel sulphate was electrolysed between the anode of lead and the cathode of nickel, when there were formed on the one side free sulphuric acid and superoxide of lead, and on the other metallic nickel. The electromotive force of this secondary element was one volt, and the caloric equivalent of the nickel 21,300. The resistance of sulphate of nickel in the electrolysis is considerable. For the separation of nickel from SO_4 an electromotive power of 2·32 volts is required. From this the tension of the current, in nickelling with sulphate of nickel and using a nickel anode, is 1·32 volt.

RESISTANCE OF CARBONS EMPLOYED IN ELECTRIC LIGHTHOUSES.—According to the *Proceedings* of the Institution of Civil Engineers, the Carré carbons employed in the French lighthouses are 0·016 metre in diameter, as used for the ordinary lights, and 0·024 metre for the "double" lights used when there are fogs. The resistance at 15° centigrade is, as nearly as may be estimated from a large number of bridge measurements, 70 ohms per square millimetre of section and per metre length, but the differences from this average amount to as much as 30 per cent. Mr. F. Lucas has made experiments to ascertain how these carbons vary in resistance with the quantity of electric current. The results led to the empirical formula

$$y = y_0 \left(1 - \frac{C}{25 \text{ amperes} + 1{\cdot}2\,C}\right),$$

y_0 being the resistance at 15° centigrade, and the quantity of current C varying from 50 to 142 amperes, when the coefficient of y_0 diminished from one-third to one-fourth. Further measurements as to the variation of temperature led to the formula

$$T - 15^\circ = \frac{C}{0{\cdot}112 \text{ ampere} + 0{\cdot}0004\,C};$$

and $y = y_0 \dfrac{1 + 0{\cdot}0005\ (T - 15)}{1 + 0{\cdot}0005\ (T - 15)}$, which may be applied for temperatures between 400° centigrade and 900° centigrade. Putting $\theta = T - 15^\circ$, the number of calories disengaged per second is

$$K = \frac{y\,C^2}{4{,}154} = \frac{0{\cdot}0747\theta^2 + 0{\cdot}000024\theta^3}{104{,}000 + 434\,\theta - 0{\cdot}397\theta^2 + 0{\cdot}000083\theta^3}.$$

The cooling surface for a cylinder of 0·016 metre diameter, and 0·400 metre length, being approximately 20,000 square millimetres, $\dfrac{K}{20{,}000}$ gives the fraction of a calorie disengaged per square millimetre of surface for each value of θ.

APPLICATION OF PHOTOGRAPHY TO ELECTRICAL MEASUREMENTS.—Messrs. Trowbridge and Hayes have devised and communicated to Silliman's *American Journal* a method by which the action of a voltaic cell can be studied at leisure, the apparatus not requiring continuous observation. A beam of light from a gas flame passes through a vertical slit placed in front of the flame, and is reflected from the concave mirror of a tangent galvanometer, of few turns of wire, through a horizontal slit, in a dark box, in which a sheet of sensitive paper is placed. By means of this arrangement of a vertical and a horizontal slit, a small point of light is obtained. A stationary concave mirror is placed near the needle of the tangent galvanometer, so that the same beam of light may be reflected by both this mirror and the one attached to the galvanometer-needle. The spot of light given by the stationary mirror serves to mark the zero point of the needle when no current is passing through the galvanometer. The photographic paper is placed in a slide which is lowered uniformly by the unwinding of a string from a little cylinder placed either upon the hour-hand or the minute-hand of a cheap eight-day clock. When the electrical current from the voltaic combination, which is being used, passes through the galvanometer, its changes in strength for different times are indicated by the relations of two lines drawn upon sensitive paper. The line drawn by the light from the stationary mirror is a straight one, and serves for the abscissa of times; while the perpendicular distances from the curve drawn by the mirror attached to the needle of the galvanometer to this axis of times give the ordinates of the curve drawn by the latter. Rapid printing paper was used, and an ordinary gas flame gave a sufficiently strong spot of light to produce an actinic effect. Knowing the distance of the galvanometer from the sensitive paper, the strength of the current may be calculated by measuring the distance between the two lines at any instant, and proceeding as with an ordinary galvanometer and scale. From a comparison of two figures the electromotive force may be determined by Ohm's law, if the distance between the lines is measured at the instant the current is made. Then knowing the electromotive force, current, and external resistance, the internal resistance can readily be found. It is evident that the same photographic method can be employed to study the swing of the needle of a short coil-galvanometer, which indicates the gradual heating of a thermopile. In this way the conduction of heat along a bar could be studied.

ELECTRICITY IN THE NAVY.—The following is an abstract of a lecture delivered by Lieutenant A. W. Chisholm-Batten, R.N., of the torpedo ship "Vernon," at the Royal United Service Institute, on the 29th ultimo, on "Electricity as Applied to Naval Purposes." He pointed out that there was no sharply defined line between the application of electricity for general and for war purposes. It was a great power in skilled hands, and could be used with safety and certainty even by slightly trained men if only enough care and thought were taken in designing the appliances so as to make their use easy and abuse difficult. Having given a brief description of how electricity for naval purposes is generated, he drew attention to its great use for illuminating purposes on board ship, the only drawback being that a failure resulted in total darkness, and great care was necessary to prevent the current affecting the compasses and chronometers. For the search light for discovering torpedo boats approaching, and for bom-

Digitized by Google

barding forts the arc light was needed, and by it a boat could be discovered at a great distance. Much use had been made of this light at Alexandria and Suakim. For signalling it had been used for years, and had been distinctly visible at 31 miles from the ship. For internal communications electricity was very valuable in ships, the applications for this purpose being already very numerous and on the increase continually. Telephones are used from ships, when moored, to the shore, and this communication has been found very useful on board the "Vernon;" and, in co-operation with the glow lamp, it was found very valuable for diving, and had already been the means of saving life. Electricity had been already successfully applied to the propulsion of launches, one called the "Australia," with a speed of seven or eight knots, having been built for £180. The application of electricity to war purposes was first in firing guns singly or by broadsides; offering great advantages in the latter case of all the guns being fired exactly at the same moment. An observer, who has not been incommoded by smoke, is therefore able to time the discharge when it will be most effective. In a heavy sea the guns can be fired at the moment the ship is upright. Electricity has proved most valuable for firing, propelling, and discharging torpedoes, a name strangely enough derived from the electric fish. For firing star torpedoes electricity is now exclusively used, and also for firing towing torpedoes, and it was now being applied to firing, propelling, and steering the fish torpedo of the type known as Sims', which is considered to have long range, handiness with the helm, a heavy charge, security from an enemy's fire, power of passing floating obstructions, not being easily seen or stopped by an enemy, its motive power always ready and not dangerous, constant speed to the end of its run, and its charge is exploded at a proper depth, to a greater degree than those of Ericssen, Lay, Howell, and Whitehead. It is made in two sizes, the larger carrying two miles of copper wire and 400lb. of dynamite. The Paulson torpedo is steered by electricity, while all torpedoes started from below the deck are discharged by electrical signals. Submarine mines, which might be defined as stationary torpedoes, could be fired either by contact or by electricity at will. In explaining the latter, which is called double observation firing or plane table firing, he said it had the disadvantage of not being applicable at night or in a fog. To obviate this, electro-contact mines were used, in which a ship blew herself up by running against one of a number of mines. The torpedo detector consists of a sinker or heavy case and a box carried in the boat from which the cable hangs. The sinker is dragged slowly along the bottom, and when it comes in contact with a mass of magnetic metal, such as a torpedo case, a humming noise is set up in the box, indicating the fact to those in the boat. In every case the various appliances were shown in actual use by the lecturer, who had skilled assistance from the "Vernon."

A SCHOOL OF TELEGRAPHY.—From an article in the *Daily News* we extract the following:—"The institution styled at full length the School of Submarine Telegraphy and Electrical Engineering, situated at the junction of Princes-street with Hanover-square, now established for some seventeen years, affords the visitor ample and interesting evidence of the giant advance into everyday life made by electricity. On entering No. 12, Princes-street, we find some forty or fifty youths engaged with various practical operations in which electricity is employed. A gas engine of eight horse-power is running to drive the dynamo machines of various construction, and the scholars are busy in testing work, in making drawings of apparatus, and in sending and recording messages by submarine telegraphy, exemplified by the mirror galvanometer and by the siphon recorder. Practical work is going on, not only in the rooms fitted with every kind of the most elaborate apparatus, but in the basement, where students are occupied in charging a formidable array of the so-called secondary batteries in which the storage of electricity is made. Others are busy in testing batteries with condensers, and at the extremity of the main floor a dark chamber is occupied by Bunsen's photometer, somewhat modified in accordance with a suggestion of Sir William Thomson, LL.D., F.R.S., who has reported most favourably on the method of instruction pursued in the school, and takes a keen interest in it like Prof. Fleeming Jenkin and Mr. Preece, who have sent their sons there, to go through the regular course of theoretical and practical instruction. This course, which extends over a minimum term of twelve months, with additional time for the same fee if the pupil be slow and painstaking rather than apt, includes the entire science and practice of applied electricity as known generally in the three great sub-divisions of telegraphy, especially as applied to submarine cables, the installation and management of electric lighting on various systems, and the construction and organisation of telephones and telephone exchanges. The practical working of various systems of telegraphy, telephony, and illumination is taught, from the management of the gas engine and various makes of dynamos to the construction of incandescent lamps, the delicate operations necessary for detecting the whereabouts of a flaw in a submarine cable, and also the use of the photometer in determining the candle-power of electric lamps and the best method of employing accumulators to advantage. This practical department is mainly got through in the morning, the afternoon being devoted to the theoretical course embodied in lectures delivered by the managers and other competent instructors on mathematics, chemistry, and general physics in relation to electricity, the general doctrine of energy, gas and other motors, electro-statics, and electro-dynamics, the relation between magnetism and electricity, including the theory of and mode of constructing dynamo and magneto-electric machines, the theory of electric lighting by means of arc and incandescent lamps, including the principles of their construction, the theory and details of construction of the various forms of secondary batteries or accumulators, the theory of the telephone and microphone, the testing and localising faults in electric circuits and engineering formulæ." We are glad to be able to add to this by no means exaggerated account of an admirable institution an extract from a letter written by Sir Wm. Thomson, dated the 16th ultimo. He says:—"Nearly eleven years ago I expressed a favourable opinion regarding the efficiency, for the teaching of submarine telegraphy, of an institution which has continued doing good work ever since that time, and which now has a well-deserved reputation as the School of Electrical Engineering and Submarine Telegraphy, of Princes-street, Hanover-square. A few days ago I had the pleasure of again visiting it, and was much pleased to find large extensions from its original province of submarine telegraphy into all branches of electrical engineering, while still retaining all its efficiency in the practical teaching of telegraphy. It is now well equipped with apparatus and appliances for the teaching of electric measurement, photometry, the management of dynamos, the practice of electric lighting, and other commercial applications of electricity. With these valuable adjuncts for illustration and practical exercise, the fundamental scientific principles are methodically taught in a series of systematic daily lectures and examinations under the superintendence of Mr. Tiddy and Mr. Carpenter, and their able assistants, in a manner which seems to me exceedingly well adapted to benefit their pupils."

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(Continued from page 23.)

Correction.—The Electrician, May 22nd, 1885, p. 23, column 1, line 14 :—In formula, after the words "which may be written," strike out the 2 in the denominator.

Line 26, insert *l* between the words "as" and "increases."

By the help of the formulæ which have been given, especially of those connected with the case in which the cable is put to earth, we can deal with some important questions in long distance telephony. The falling off in current corresponds to the failing in intensity of tone produced. The fact that this falling away in current depends upon the period, being greater as the period is smaller, will explain the alteration in character of a composite tone, those components which have a higher pitch suffering more decay than lower notes.

The subjoined table will facilitate the calculations of such effects :—

θ	$\frac{\cosh\theta+\cos\theta}{2}$	$\frac{\cosh\theta-\cos\theta}{2}$	$\cosh\theta$	$\cos\theta$
0·0	1·	·0	1·	1·
·01	1·	·0000500	1·0000500	·9999500
·02	1·	·0002000	1·0002000	·9998000

2·2	1·9897036	2·5782048	4·5679084	– ·5885012
2·3	2·1854716	2·8517475	5·0372191	– ·6662759

As an example of the use of the table, suppose the following problem :—

A cable possessing ·2 microfarad of capacity per kilometre, and a resistance of 2½ ohms per kilometre, is 40 kilometres long. What will be the relation of the current at the sending end to that at the receiving end for a tone whose period is $\frac{1}{500}$ of a second?

Adopting quadrant units, we find that since the cable has ·2 microfarad per kilometre, it has ·002 farad in one quadrant; therefore, C = ·002.

Since the cable possesses 2·5 ohms in one kilometre, it has 25,000 ohms in one quadrant; hence $\rho = 25{,}000$. The period is $\frac{1}{500}$ of a second; hence $2T = \frac{1}{500}$.

Since the length of the cable is 40 kilometres, l = ·004 of a quadrant; hence a, which is equal to $\sqrt{\rho\frac{C\pi}{2T}}$, has for value $\sqrt{25{,}000\times\cdot002\times\pi\times500}$; or $a = 280{\cdot}25$. Hence $2al = 2{\cdot}24$, which is the number corresponding to θ in the table.

Looking, therefore, horizontally between the lines headed 2·2 and 2·3, and under the column headed $\frac{\cosh\theta+\cos\theta}{2}$, we shall be able to deduce the number 2·06 by interpolation. This number is the relation of the square of the current at the sending place to the square of the current at the receiving place. The relation of the currents themselves will be the square root of this number, *i.e.*, about $\frac{144}{100}$.

Now, suppose we investigate what takes place with the note one octave lower than that already considered. In this case, $2T = \frac{1}{250}$, and a will be found to be 198·17, and $2al$ will be 1·59, the number corresponding to θ in the table.

The value of $\frac{\cosh\theta+\cos\theta}{2}$, for this value of θ, will be found from the table to be 1·265, and the square root of this is 1·125, so that for this note the telephone current is reduced in the ratio of 112 : 100. For higher notes, the falling off of the currents would increase very rapidly. At the octave above the first note considered, the current would be reduced more than in the ratio 300 : 100.

Now the notes considered come well within the range of human tones in speech. The fundamental tones of the voice are, moreover, richly accompanied by harmonies of a high order, by means of which, however unconsciously, we interpret under ordinary circumstances the sounds received upon the ear. All such harmonies would suffer very materially in the course of the transmission.

Thus, at the end of a cable of any considerable length and capacity the various tones of the voice would be received in a state of degradation depending upon their pitch. If this were not the case, if all the tones were reduced in strength in the same proportion, a relay might be employed to restore the various currents to their original intensity, or to one in which the ear would readily appreciate the meaning of the tone. But the ear has not the synthetic power of reconstructing a composite tone from the wreck of variously degraded components. In this consideration reside the limits of telephony. Until this consideration is more clearly understood than it seems to be at present, people will fail to understand the exquisite nonsense to which they are often now content to listen about the possibilities of being able to listen to the minutest modulations of voice of a transoceanic prima donna, and so on. It would be more to the purpose to endeavour to keep $2al$ small. Lord Rayleigh at Montreal looked to alternating currents "to educate so-called practical electricians whose ideas do not easily rise above ohms and volts." It is to be hoped that this anticipation will be realised, for unfortunately the imputation conveyed is too well deserved. In a book specially published by the Institution of Civil Engineers in 1884, upon the practical Applications of Electricity, there is a paper by Sir Frederick Bramwell on Telephones, in which the following sentence occurs :—

"You all know that if an iron plate . . . . be caused to approach towards or recede from a permanent magnet, that magnet being surrounded by a coil of insulated wire, there will be set up in the coil of wire electric currents, which will vary in direction according as to whether the plate is approaching the magnet or is receding from it."

In this sentence it is clearly assumed that the induction, whose phase does accompany the phase of the plate's motion, is also accompanied in phase by the current. The mistake is made that induction is of the nature of current, instead of electromotive force. The induction produced by the plate's motion is the impressed electromotive force, but there may arise electromotive forces of self-induction, and those due to capacity in the conductor, which would cause the current to have a phase differing from that of the plate's motion, and to suffer at the same time a diminution in strength, both effects depending upon the pitch of the note producing the vibrations of the plate.

Digitized by Google

These are the effects which will ultimately give a limit to telephony. But further on in the same paper, we read "As many persons have asked, what is the limit of possibility? I would say that I should think it depends practically on the excellence of the insulation and the avoidance of induced currents."

Now, if by induced currents is meant currents produced by accidental induction from outside, it seems likely that such currents would not so materially affect the interpretation of the sound as would the degradation of the currents which it is desired should be transmitted. For the ear, which is ultimately the organ to interpret, is every day practising the art of discriminating between two or more contemporaneous and superimposed sounds. The ear is, in fact, an excellent analyser, but for the process of recomposition necessary before a degraded composite tone can be truly interpreted something more than power of analysis is necessary, and this the ordinary ear does not possess.

To return to investigation. The dynamometer reading at distance x from the generator in a cable put to earth at the distant end is

$$\epsilon^2 \frac{C\pi}{2T\rho} e^{-2ax} e^{-2a(l-x)} \left\{ e^{2a(l-x)} + e^{-2a(l-x)} + 2\cos 2a(l-x) \right\}$$

$$= \epsilon^2 \frac{C\pi}{T\rho} e^{-2al} \left\{ \cosh 2a(l-x) + \cos 2a(l-x) \right\}$$

$$= \epsilon^2 \frac{C\pi}{T\rho} e^{-2al} \left\{ \cosh 2ad + \cos 2ad \right\}; \text{ where } d \text{ is the distance from the remote end, and for a cable whose end is insulated, it is}$$

$$\epsilon^2 \frac{C\pi}{T\rho} e^{-2al} \left\{ \cosh 2ad - \cos 2ad \right\}.$$

The relation is $\dfrac{\cosh 2ad + \cos 2ad}{\cosh 2ad - \cos 2ad}$.

Now, a reference to the second and third columns of the table shows that the numerator of this fraction does not always exceed the denominator. At certain values of $2ad$, those in fact for which $\cos 2ad$ is equal to zero, which recur periodically, the numerator is equal to the denominator, and the excess changes sides. The first of such cases occurs between $\theta = 1{\cdot}5$ and $\theta = 1{\cdot}6$, *i.e.*, when $\theta = \frac{\pi}{2} = 1{\cdot}57$.

If, therefore, the length and structure of the cable and the period of alternation are such that $2al$ is greater than $1{\cdot}57$, there will actually be regions of the cable at which, as far as the intensity of the currents received is concerned, it would be better if the circuit were an open one than that the distant end should be put to earth; and as we increase the length of the cable this state of things alternates with the other at fixed distances from the far end in the following way:—

Deduce a distance λ such that $2a\lambda = \frac{\pi}{2}$;

whence $$\lambda = \frac{\pi}{4a} = \frac{1}{4}\sqrt{\frac{2T\pi}{\rho C}},$$

and set off from the far end distances corresponding to λ, 3λ, 5λ, &c.

Then in the region within λ of the far end the current will be greater when the end is put to earth. In the region, length 2λ, between 3λ and λ from the far end, the current will be greater when the end is insulated. In the next region of length 2λ, it is best to put the far end to earth. And so on alternately for every length of 2λ. At the points where these alternating regions join, there will be a constant current whether the end is put to earth or not.

This distance 2λ is one quarter of the wave length of the undulation in the infinite conductor (*vide* p. 510, Vol. XIV.).

(To be continued.)

NOTE ON THE REGULATION OF DYNAMOS.

An interesting peculiarity exhibited by self-regulating dynamos wound for constant difference of potential is that such machines regulate equally well at any speed within fairly wide limits. This peculiarity must be common to all compound machines so wound, but the degree to which it is manifested depends on the construction of the machines. In this article an attempt will be made to explain the cause of this phenomenon.

The simplest expression for the E.M.F. of a series dynamo is given by the equation

$$E = N(a + bC) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where E is the E.M.F., C the current, a a constant depending on the permanent magnetism, and b a constant depending on the winding of the field magnets, &c. This equation means that when the circuit is open there will be a certain E.M.F. exhibited by the machine which is due only to residual or permanent magnetism, and that when the circuit is closed through a resistance and a current allowed to flow there is added an E.M.F. due to the increased magnetism of the fields which is proportional to the current. The equation is not true for all currents flowing through the machine, it is only approximately true for some little distance along the characteristic curve; nevertheless it is quite sufficient for our purpose, and it is the fundamental equation which serves as a basis for the construction of compound self-regulating machines. In such machines we have a a constant depending on the magnetism furnished by the shunt coil, and b a constant depending on the winding of the series coil, &c. Calling R the external resistance, r the combined resistance of the armature and series coil, C the current through the lamps, and c the current through the shunt coil, we have

$$CR + r(C + c) = N\{a + b(C + c)\} \quad . \quad . \quad . \quad (2)$$

Remembering that b depends on the series winding of the magnets, and that the E.M.F. added by the series coil when the circuit is closed is proportional to the current, we can, if we make $Nb = r$, write

$$CR = Na. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

If this condition is fulfilled in the winding of the series coil the machine will be constructed so that at the speed N the series coil will add to the circuit an E.M.F. equal to Cr, and this done the difference of potential at the terminals C R is a constant for all currents, and depends only on the strength of field supplied by the shunt coil and on the speed of the machine. Since the shunt coil is connected to the terminals of the machine, where the difference of potential is by hypothesis to be constant, the amount of magnetism furnished by the shunt is constant.

It is unnecessary to take up space by drawing the saturation curve of a dynamo. Such a curve is obtained by separately exciting the machine, running it at a constant speed, and observing simultaneously the E.M.F. and the current flowing round the magnets. The former being plotted as ordinates and the latter as abscissæ, we get a curve representing the relation between the strength of field and the excitation given to the magnets. Readers will remember that from the origin of the curve for some little distance the line is approximately straight, but that very soon it bends over towards the horizontal. Now, all expressions for the winding of compound machines, so far as the author knows, are based on the conception—a false one, as we shall see—that there is so much iron in the magnet cores that this curve for the whole of the excitation supplied by both shunt and series coils remains approximately a straight line. This means, of course, that the strength of field produced in the magnets is throughout proportional to the exciting current, and as a corollary it has been assumed that the machine will only regulate at one speed. This speed has been termed the critical speed for the combined resistance of the armature and series coil, a term which has no very distinct meaning in the case of compound machines, as the speed can generally be varied more than 50 per cent. without detriment to the regulating

Digitized by Google

power of the machine. It must also be remembered that in a machine having cores of excessive softness, were the strength of field proportional to the exciting current the machine on open circuit would be necessarily running at a speed which would be critical for the resistance of the shunt coil, plus the armature, plus the series coil, and the E.M.F. would be in consequence indeterminate. When thus running on open circuit, both shunt and series coils furnish a certain excitation to the magnets, and on the assumption that each ampere-turn furnished by the series coil has the same absolute value as each ampere turn furnished by the shunt coil, as far as strengthening the field is concerned, we have for the proportion of series to shunt wire the expression

$$\frac{\text{Turns of series wire}}{\text{Turns of shunt wire}} = \frac{\text{Resist. of arm.} + \text{R of series coil}}{\text{Resistance of shunt coil}}$$

The series coil when the machine is running on open circuit furnishes the E.M.F. necessary to send the exciting current through the armature and series coil, and the shunt coil the E.M.F. necessary to send the current through itself. When the circuit is closed the ampere turns added by the series coil should be just sufficient to raise the E.M.F. by an amount equal to $C\,r$, where C is the current through the lamps. But the expression given above, based as it is on the assumption that the saturation curve is a straight line right from its origin to the extreme limit of excitation, always gives the turns of series wire much too low.

The effect mentioned at the beginning of this article, namely, the regulating of the machine at several different speeds, is entirely due to the bending over of the characteristic, and in all cases the curvature has become very decided while yet the machine is running on open circuit. The E.M.F. added by the series coil for any particular speed depends on the value of b. If we draw a saturation curve to show the relation between the current exciting the magnets and the E.M.F. for any particular speed, we shall find that b is continually altering its value. For instance, in a series machine designed to give a current of 20 amperes the E.M.F. added to the machine, due to the current being increased from five amperes to 10 amperes, is much greater than the E.M.F. added by an increase of current from 10 to 15 amperes. This is simply because b gets less and less as the magnets get more saturated. It will be seen that in the compound machine the value of b for a given number of series turns depends on the amount to which the magnets are saturated by the shunt and series coils before the current is allowed to flow through the lamps. If the magnets are only partially saturated the value of b is high, if fairly well saturated the value of b is low. In any case its value is proportional to the tan of the angle which the curve makes with the horizontal at that point, which represents the excitement given to the magnets by the shunt and series coils before the circuit through the lamps is completed. If this is true, obviously each ampere-turn furnished by the series wire has a very different value to that furnished by the shunt; and in illustration of this fact we have only to cut out the shunt wire of a machine and run it at the speed at which it runs as a compound machine, when we shall find that from the series wire only we shall get something like a difference of potential of 60 volts at the terminals with the full current on in a machine which, at the same speed, regulates at 100 volts with the shunt coil in. This shows that without the shunt coil in action the value of the series wire is very much greater, for the coil which merely furnishes an E.M.F. sufficient to send the current through the armature and itself when the magnets are excited by the shunt is capable of producing an E.M.F. of over 60 volts when there in no initial excitation. This experiment also shows us that for a given number of convolutions of series wire and a given resistance of armature and series coil a certain relation must exist between the speed of the machine and the degree to which the magnets are excited by the shunt coil—in other words, since the value of b depends on a, and since the condition of regulation is that $N\,b = r$, it is only when the degree of saturation produced by the shunt is such as to make $N\,b = r$ that the machine will regulate.

The equation $E = N\,(a + b\,C)$ has been given as the fundamental expression for the E.M.F. of a compound dynamo. It has been shown, however, that the value of b depends on a, and that it is continually changing as a is increased or diminished. But the value of b is assumed in the construction of compound machines to remain constant for the distance along the saturation curve which represents the difference in the number of the ampere-turns exciting the magnets when the lamp circuit is open and the number of ampere-turns when the full current is flowing through the machine. That it is not quite constant even for this distance is shown by the slight curvature in the characteristic of the compound machine, but the error is not great and forms no practical barrier to the use of these machines.

From the foregoing remarks we can clearly understand how the machine regulates at several different speeds. The magnetism furnished by the shunt coil depends on the speed of the machine; as the speed is increased a is increased, the magnets being saturated by the shunt coil to a greater degree than formerly. But we have seen that in moving the point corresponding to a further up the curve the value of b is diminished. The E.M.F. added by the series coil at the new speed is still, however, equal to $C\,r$, because in consequence of N having increased and b diminished the product $N\,b$ has still its former value. In consequence of the saturation effect the machine will regulate at all speeds where the increase in N compensates for the diminished value of b, or for all speeds where $N\,b = r$.

W. B. Esson.

CORRESPONDENCE.

ELECTRICAL NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I think English electricians should feel much indebted to Prof. Jamieson for bringing forward the subject of uniform electrical notation and nomenclature. We were fast drifting into a position in which this work would have been done for us by others, and then, when too late to discuss the matter effectively, a few of the more prominent among us would have been invited abroad to accept and adopt the new notation, cut and dried, amidst a profusion of hospitalities. This is very pleasant from a social point of view, but hardly consistent with the position which this nation has hitherto held in connection with the development of electricity.

I am glad that you recognise the fact that "the men of theory must of necessity to some extent give way to the men of practice." The former are well able to take care of themselves, but I doubt whether it is possible to make one system suitable for both—their wants are so entirely different that I think it would be almost wiser to recognise the fact and act upon it. The electrical industry is fast becoming a common handicraft. A large generation of working men has risen who have no time or even desire to study the theory of their trade, and everything should be made as easy as possible for them. They have only just sufficient education to interpret the very simplest equations, and for their use and benefit I would advocate that our new electrical measures should be ordinarily represented *by their first letters only.* I would even go further and advise that in their case the time-honoured $C = \frac{E}{R}$ should be abolished, and that $A = \frac{V}{O}$ should be substituted. I know how revolutionary this will appear; but there are two parties to be considered. To a practical algebraist there is no appreciable effort involved in mentally converting his amperes, volts, and ohms into C E and R, and in shaping the familiar equation into the form which he requires, and in afterwards re-converting his results back again into the then equivalents A V and O. This has to be done every hour, and is very easy to most people when sitting at the table; but how unsuited is it to the wants of the working engineer, with his hands greasy with oil, chalking his figures on a board amidst the whirr of dynamos. For him there should be no conversion of symbols

Digitized by Google

As a specimen of what is more suited to his case, I venture to subjoin a set of workman's formulæ, in which initial letters only are used, and by which he can obtain the values of A V O, &c., from their various combinations. Here he finds a formula suited to every case he can meet, and he writes down his measures and obtains his results in familiar signs with scarcely an effort of thought. This simple nomenclature is equally suitable for other electrical formulæ, and is in fact being adopted by many electrical writers. Whether it will be accepted by more advanced mathematicians is another question, as they have to deal with other subjects besides electricity. I am quite aware that such a table as that given below is to them an abomination. What is the use, they ask, of so many figures? The whole of the formulæ can be instantly produced when required by any one ordinarily familiar with Ohm's law; and they turn away from such a mass of symbols with disgust. But these considerations do not apply to the working mechanic, and he ought not to be called upon to change the form of an equation or to turn C E R into A V and O amid the whirl of his machinery. I am inclined to think, upon the whole, therefore, that two systems of notation must come into use, the one for working men, the other for mathematicians, though they would not differ materially from each other.

I trust these views will meet with due consideration by the committee who are to be appointed to consider the question.—Yours, &c., LATIMER CLARK.

ELECTRIC LIGHTING NOTES.

$$\left(C = \frac{E}{R}, \text{ or } A = \frac{V}{O}\right).$$

Amperes A $= \frac{V}{O} = \frac{W}{V} = \sqrt{\frac{W}{O}} = V \times M = \frac{C}{t \text{ seconds}}$ $= 10^{-1}$ C.-G.-S. units.

Volts V $= A \times O = \frac{W}{A} = \sqrt{W \times O} = \frac{A}{M} = 10^{8}$ units.

Ohms O $= \frac{V}{A} = \frac{W}{A^2} = \frac{V^2}{W} = \frac{1}{M}$ $= 10^{9}$ units.

Mhos M $= \frac{A}{V} = \frac{A^2}{W} = \frac{1}{O}$ $= 10^{-9}$ units.

Coulombs C $= A \times t = \frac{V}{O} \times t$ $= 10^{-1}$ units.

Farads F $= \frac{C}{V}$ $= 10^{-9}$ units.

Volt-amperes V A $= V \times A = \frac{V^2}{O} = A^2 \times O = W = \frac{J}{t}$ $= 10^{7}$ ergs per sec.

Watts W $= V \times A = \frac{V^2}{O} = A^2 \times O = \frac{C \times V}{t} = \frac{J}{t} = 10^{7}$ ergs per sec. $= 737$ foot pounds per sec. $= 1019$ kilogrammetres per second $= 44{\cdot}236$ foot-pounds per minute $= \frac{1}{746}$ horse-power.

Joules J $= W \times t = V A \times t = C \times V = A^2 \times O \times t = \frac{V^2 \times t}{O} = 10^{7}$ ergs $= 2381$ calorie, or water-gramme degree Cent.

Candle-power (C.P.) $\frac{V \times A}{C.P.}$ = watts per candle.

BLIND MATHEMATICS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: It is one of the dangers which beset a mathematical treatment of physical science that from time to time instances will occur in which formulæ are handled after a blind fashion, and mathematical processes, sometimes simple, sometimes intricate, are carried out without any consciousness of the physical sense either of the first line from which the deduction is made, or of the last line which expresses the result arrived at.

Having recently met with an instance of this, which can scarcely be regarded as insignificant, I venture thus to trespass on your much sought-for space.

It is well known that when a short piece of fine platinum wire or carbon filament is made to form part of a powerful circuit, intense heat is developed in it, as we witness every day in an incandescent lamp. It has been found experimentally that the amount of heat so developed under varied circumstances is expressed by the simple formula, $H = C^2 R$. Had formulæ ceased here we should have been well-informed in the matter; but some expert mathematician, reflecting on the circumstance discovered by Ohm, that the current strength in a circuit was a function of the resistance in it, has simplified the expression by substituting for C the value $\frac{E}{R}$ derived from Ohm's formula, whence the heat formula becomes $H = \frac{E^2}{R^2} . R$, and finally $H = \frac{E^2}{R^2}$.

Had the author of this formula reflected on its meaning, he would have noticed how it implied that a minimum of resistance, such as that obtained by substituting a silver wire for the platinum, would yield a greater heating effect, whilst we know that the contrary is the case. Taking the mathematician on his own ground, he can be answered by pointing out that "R" in the heat formula, $H = C^2R$, is not identical with "R" in Ohm's formula, $C = \frac{E}{R}$, and, accordingly, he has made the false inference (rendered more conspicuous by an accent) that $\frac{R'}{R^2} = \frac{1}{R}$. Meanwhile, the fallacious deduction, $H = \frac{E^2}{R}$, has so far deceived the scientific world that a learned professor has aided us with a graphical representation of it, in which the perpendicular from the right angle of a triangle forms a mean proportional (like E) between the segments of the hypohtenuse (representing H and R respectively).

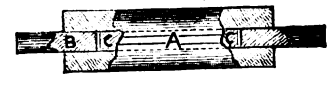
A heat formula will be useful only so far as it supplies a rule for determining the amount of heat that will be developed in any particular portion of a circuit. The formula $H = \frac{E^2}{R}$ gives such rule, but it is a false one. I am surprised at finding such an oversight in a work of the standing of "Ganot's Physics," where I accidentally met with it, and can only attribute the occurrence to the author not being duly conscious of the physical import of the symbols and expressions he was using.—Yours, &c., E. ALDRED WILLIAMS.

May 29, 1885.

CONTACT PIECES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It occurred to me if contact pieces for microphone transmitters were constructed as per sketch, a great saving of labour and a minimum amount of breakages in manufacture would occur.



Having constructed an instrument with three such contact pieces arranged parallel, and having obtained satisfactory results therefrom, perhaps this letter may prove of interest to some readers.

A is a piece of soft core arc lamp carbon, with about ¼in. of the core extracted from each end.

*BB are pieces of carbon, such as used for semi-incandescent lamps.

CC represent the unextracted core.—Yours, &c.,

London, May 25th, 1885. ST. GEORGE W. DAVEY.

* BB form loose contacts in A.

MILITARY CABLES IN THE FAR EAST.

A short time ago we had to warn the investing public against a project then talked about for connecting South Africa direct with our Indian Empire. The objections to that scheme as a commercial undertaking were grave and conclusive. The route would be in very deep sea, the bottom of which has been but imperfectly explored; the sea itself would be practically closed by prevailing winds to all repairing ships for a great part of the year; and, what is of still greater importance, the commercial traffic between South Africa and India would not pay expenses. In all probability this very unpromising adventure was suggested by the prospects of war, an excellent reason for laying a military cable, but the very worst for speculating in commercial cable laying. We repeat here what we have had occasion to state more than once before that periods of political disturbance or warfare are bad for telegraphs as for all other trades, the loss of commercial traffic being far from compensated by increase of war telegrams.

But these objections do not apply to cable laying for Imperial defensive purposes; and it is with feelings of something akin to shame and dismay that we see these necessary measures apparently set aside as matters of no present importance. If we are to credit the Hong Kong correspondent of *The Times*, whose letter we partly reproduced in our last issue, nothing whatever has been done, and nothing is intended to be done, towards connecting such places as Hong Kong and Singapore by means of direct cables independent of a possibly hostile territory. The China Seas are by no means the only places where cable laying has been conducted on purely commercial principles, short lengths being used by preference, and points of intermediate landing chosen with natural regard for picking up traffic on the way. Consequently, if we cast our eyes over any telegraph map we see that not infrequently the through working, of coast cables especially, is at the mercy of some colony belonging to a foreign Power, who, if not benevolently neutral, might intercept our communication in time of war, and who, of course, would destroy it if that power were one of the belligerents.

Such a contingency is rather alarming for owners of cables; but the cost of duplicate, independent cables would be so great that the risk is run as the cheaper of two evils. But the case assumes a very different aspect when Imperial interests are concerned. Those interests demand at least as much attention as the commercial—the one set of interests, in fact, being bound up with the other. Recent events have attracted attention to our complete dependence upon the commercial system of submarine communication, and to the danger to our colonies, coaling stations, and even to our Indian Empire, consequent upon there being no State cables on which in time of war we could rely both for naval and military intelligence, and as alternative routes when commercial cables have been severed. It was hoped that amongst the plans for completing our naval defences this one of laying supplementary, if not purely military cables, which has been recommended by the highest authorities, would have received prompt attention. This expectation is not to be realised, it seems, if the case of Hong Kong and Singapore, which is really a very pressing one, may be taken as a proof of what the Government do *not* intend to do.

The Times correspondent points out, in reference to this particular locality, that to a nation like ourselves, with the enormous interests involved, one would imagine that we should recognise the absolute necessity of being forearmed by being forewarned, and this at any cost. Far from costing an enormous sum, it might have been accomplished by a small guarantee contributed by the Imperial Government, and the cable might have been working now if that condition had been complied with. This is what we have stated all along; and in most cases a company could be found to lay the cables and maintain them if the Government only went to the expense of a comparatively small subsidy. If the Admiralty will not lay cables for itself, the cheapest alternative is to help somebody else to lay them. But, according to *The Times* correspondent, the responsible officials have virtually replied that "If the colonies and Indian ports want torpedo boats and English cables they must pay for them themselves"; and he adds "that a terrible blunder will be committed if this attitude is persisted in."

Now that immediate hostilities have been avoided, we may be permitted to hope the blunder is not so terrible as this writer apprehends. But it is a blunder all the same, and one which could be more easily repaired in time of peace than on the outbreak of a war. There is still time to urge this consideration on the official mind; and we may hope that not only the Colonies, who are directly concerned, but Cable Companies who are indirectly interested, in obtaining these supplementary and independent cables will spare no effort to get them laid down. England has been spending enormous sums for the peaceful purpose of pretending she was going to

Digitized by Google

fight; more than this, the net outcome of it all is to saddle the country, and her chief Imperial dependency with a vast outlay on defensive works now rendered indispensable. Compared with these charges, the cost of subsidising, or even of purchasing and laying a few cables, would be a mere bagatelle, and ought not to be grudged where the confidence and security of a widely scattered Empire are involved.

As to the Colonies paying for these necessities themselves, that is the sort of reply we should give to projects of long deep-sea cables, which have no great value except as aids to the Government. If the Government wants such cables let the Government pay for them. But it is not the right answer for an Imperial Government to make to its dependencies. It is outside our province to deal with the political aspect of a question of this kind; but one thing is obvious from commercial, to say nothing of ethical, considerations—namely, that as we founded these colonies in the interests of British trade, it would be suicidal as well as cowardly to leave them to fend for themselves when threatened by a foreign foe. We do not believe, however, that any such desertion is contemplated, but rather that if the proper steps are taken they will overcome the economic and short-sighted inertia of our rulers.

ON OBSERVING AND RECORDING THE VARIATIONS OF A CURRENT.

BY C. W. S. CRAWLEY AND F. B. O. HAWES.

(Continued from page 47.)

The value of the readings in volts at the galvanometer terminals was taken by a potentiometer method. A standard Daniel, A (Fig. 7), of about 4ω internal resistance was circuited

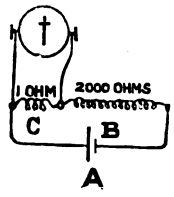

FIG. 7.

through two coils in series; one, B, of 2,000ω, and the other, C, of 1ω. The terminals of C were then also joined to the galvanometer terminals and the deflection of, say n, centimetre obtained. The E.M.F. at the terminals of the coil C is $\frac{1}{2000+1+4} \times 1{\cdot}079$ volt $= {\cdot}00538$ volt (the galvanometer resistance being so high that the joint resistance of the one-ohm coil and the galvanometer may be taken as 1ω). Therefore the constant of the galvanometer is $\frac{5{\cdot}38}{n}$ millivolts per centimetre.

This constant, of course, only holds good as long as the sensitiveness of the galvanometer remains constant—that is, so long as the "time of swing" of the needle remains unaltered; for the sensitiveness varies directly as, and the constant therefore inversely as, the square of that time. The time of swing was always taken as one-fifth of the time between the first and sixth passage of the spot over the zero mark in the same direction, after being deflected to the edge of the paper, and then allowed to swing freely. The time of one complete swing thus obtained will hereafter always be called "τ."

The constant for any time of swing having been found as above, it can be calculated for any other time. Thus let κ_1 be the constant for a time of swing τ_1 (that is 1 cm. deflection $= \kappa_1$ millivolts) and κ_2 the constant when the time is altered to τ_2 seconds per swing, then

$$\frac{\kappa_2}{\kappa_1} = \frac{\tau_1^2}{\tau_2^2} \quad \therefore \quad \kappa_2 = \kappa_1 + \frac{\tau_1^2}{\tau_2^2}.$$

It was found to be convenient to frequently alter τ so as to suit the various classes of currents under observation. Thus, a slowly varying current is best observed with a slow swing, say 10 or 15 seconds, while for one with sharp, short, variations τ would be made as small as possible, say 1 to 2 seconds, which is as quick as can be accurately followed by the pencil.

When taking a curve, if the variations are small compared to the total current, it is often convenient for their better observation to use a higher or no shunt on the galvanometer, and an inferred zero. Thus, suppose that with the "100" shunt and zero in the middle of the paper the current gives a deflection varying between 22 and 23 centimetres. Now let the "10" shunt be put on, the deflection becomes ten times greater, and the deflections will vary between 220 and 230 centimetres from the centre of the paper, and consequently not appear on it.

If, now, the controlling magnet of the galvanometer be turned so as to bring the spot again to the centre of the paper, the variations may be recorded on a scale ten times as large as before, zero being about 225 centimetres from the centre of the paper. When the controlling magnet is used in this manner it is important to know directly how much zero has been shifted, without having to calculate it from the deflection at the moment when the shunt was altered. This is more especially necessary in the case when the mean current slowly increases or diminishes, when it may again be necessary to shift zero owing to the position of the spot passing beyond the limits of the paper. The controller was therefore calibrated as follows:—A Daniell cell was circuited through a bare G.S. wire, stretched on a board, or wound on a cylinder, in series with a sufficient resistance to prevent polarisation. One terminal of the shunt box was joined to one end of the G.S. wire, and the other to a sliding contact on the wire. A measure was then placed on the paper, and the sliding contact adjusted till a deflection of exactly ten centimetres was obtained with the "10" shunt on, say to the left. The "10" shunt being now taken off the deflection became ten times as great, viz., 100 cm., the spot being off the paper. The controller was now turned round till the spot was brought back to zero. On one end of the controller a pointer was fixed, moving over an arc, and on the arc, at the spot at which the pointer stood, "+100" was marked. The battery being now reversed, the spot was again brought back to zero by turning the controller in the opposite direction, and "−100" marked at the spot where the pointer then stood, the normal position of the controller, *i.e.*, that position which, when no current is passing, allowed the spot to remain at the centre of the paper, being marked "0." In a similar manner the arc was graduated for every 50 cm. up to 500 both right (−) and left (+); so that, when taking a curve with inferred zero, all that was necessary was to bring the spot on to the paper and note down the reading of the pointer; thus +250 showed that the zero line was 250 cm. to the left of the middle of paper; −400, that it was 400 cm. to the right.

This method of observation, it will be seen, gives a very largely-increased range of observation. The paper used was only about 70 cm. broad, but by the above means slight variations in a large current were recorded on the same scale, as if the paper had been several metres wide.

It has been said that it was found convenient to work with different times of swing. This of course altered the effect of the controller. The correction can, however, be calculated on the same lines as that for the constant "κ_1" above. Thus, if the controller was calibrated when the time of swing was τ_1 secs., and this be altered to τ_2 secs., the reading of the controller in centimetres must be multiplied by $\left(\frac{\tau_2}{\tau_1}\right)^2$. Alterations in the time of swing were made by a second magnet, called the adjuster; as, the controller having been once calibrated at a certain distance from the needle, it was necessary to keep it fixed at that distance. The controller used was 90 cm. long, and pivoted on the ceiling 130 cm. vertically over the galvanometer. It was first strongly magnetised, and then tapped with a wooden mallet, so as to obtain a constancy of magnetisation, as suggested by Prof. Hughes.

When "τ" is frequently altered it will be found convenient

Digitized by Google

to calibrate the controller not in centimetres, but in millivolts; for, as will be shown, this holds good whatever the rate of swing may be, thus saving calculation.

The constant was first taken as above, say, ·08 millivolt per centimetre, then 1 millivolt $= \frac{1}{\cdot 08} = 12{\cdot}5$ cm. The controller was then calibrated, using the G. S. wire as before, but taking deflections of 12·5 cm., 25 cm., &c., instead of 10, 20, &c. The marks on the arc of the controller then represented 10, 20, &c., millivolts, instead of 100, 200, &c., cm.

Now, a certain current of $\frac{n}{g}$ milliamperes through the galvanometer due to a difference of n millivolts at its terminals, always exerts a certain definite force on the needle when at its zero position, whatever the time of swing may be. The tan of the angle of *deflection* varies as the square of the time of swing, though the force exerted by the same current on the needle when at zero is always the same.

In the same way the force exerted on the needle by the controller when turned through a certain angle θ is always the same whatever the time of swing may be, though the number of cm. that zero is shifted varies as the square of that time. If, therefore, the controller, at a certain position counteracts the deflection due to n millivolts when the time is τ secs., it will do so whatever the time of swing may be. (Also, it may be noted, in passing, this calibration holds good, whatever distance the scale or paper be moved from the galvanometer.)

When thus calibrated the readings on the arc must of course be multiplied by the multiplying value of the shunt, if one is used.

This form of controller causes an error in working, and for more accurate determinations the authors have devised and used two other forms which overcome the difficulty.

With regard to the error. First, considering only the effect of the controller and current, and neglecting that of the earth and adjuster, let a b (Fig. 8) represent a needle (in plan) and O

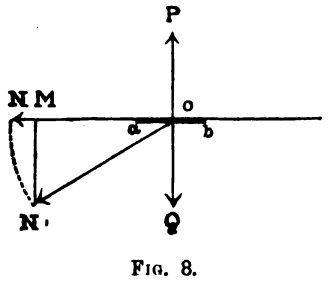

Fig. 8.

its centre of suspension, then the forces acting at O are equal and opposite. Taking those acting in one direction, let O N represent in magnitude and direction the force of the controller, which is vertically above the needle, and O P the force exerted by the current tending to deflect the needle from its original position in the line O N. Now, to counteract the effect of the current and retain the needle in its original position, the controller must be turned to a position, O N, such that, resolving O N into two forces, O M in the direction O N, and O Q at right angles to it, the latter is equal and opposite to O P. The time of swing, and therefore the sensitiveness, depends solely on the force in direction O N, that is on the component O M, which we may call the controlling component, O Q having no effect on the sensitiveness.

Calling θ the angle N O N through which the controller is turned, we have M O = N O cos θ, and the sensitiveness becomes greater in the ratio 1 to cos θ. Taking the forces of the earth and adjuster into consideration, and calling them E and A respectively, the variation of the controlling force when the controller is turned through θ^0 is from E + A ± C to E + A ± C cos θ, the + or − sign being taken according as the controller is set to act in conjunction with or in opposition to the earth.

The latter arrangement is the better, as will be seen from the following considerations:—

Call C_1 the controlling force of the controller when at zero, and C_2 the controlling component when turned through θ.

Then it has been shown that $C_2 = C_1 \cos \theta$; or writing $C_1 (1 - \cos \theta) = a$, then $C_2 = C_1 - a$.

Calling F_1 the total controlling force, which gives a swing of τ seconds with the controller at zero, and F_2 the force when the controller is turned through θ, then, when the controller is acting with the earth,

$$F_1 = E + A + C,$$
$$F_2 = E + A + (C - a);$$
$$\therefore F_2 = F_1 - a.$$

When the controller is against the earth, in order to maintain "τ" constant, the total controlling force, when the controller is at zero, must remain the same as before; and to get this the action of the adjuster on the needle must be increased by an amount = 2 C.

Calling F_3 the controlling force when the controller is turned through δ, we have

$$F_1 = E + (A + 2C) - C$$
$$(= E + A + C \text{ as before}),$$
$$F_3 = E + (A + 2C) - (C - a);$$
$$\therefore F_3 = F_1 + a.$$

Now, it is obvious that this is preferable to the last equation, for, to take an extreme case, let $a = F_1$. Then if the controller is with the earth the controlling force vanishes, while, if against the earth, the controlling force is only doubled.

It is thus evident that the above method of altering zero is unsuitable for large alterations, or when the total controlling force is small—that is when τ is large. For small alterations with fairly quick swing it is, however, a very convenient form.

The following two forms of controller have no effect on the sensitiveness, as their action in the needle is solely in the line P Q of Fig. 8. One form of controller used was composed of two magnets of equal strength and size, pivoted together at their centres, so that either their like or unlike poles could be brought together. The controller was placed vertically above the needle and the two magnets so geared together that if one were rotated through any angle in a horizontal plane the other was also rotated through an equal angle in the opposite direc-

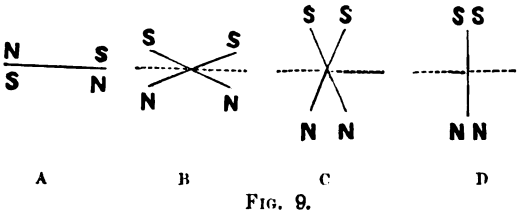

Fig. 9.

tion. A, B, C, and D (Fig. 9) show four positions of the magnets in plan, A being the zero position when the opposite poles are together and neutralise one another; D is the position of maximum effect when the like poles are together, and B and C intermediate positions. The needle underneath when at zero lies in the dotted line, and it will be seen that in every case the action of the controller on the needle is solely at right angles to the dotted line. It has therefore no effect whatever on the time of swing. This form was found very convenient when it was preferable to have the controller above the instrument; when it could be placed behind or in front another and

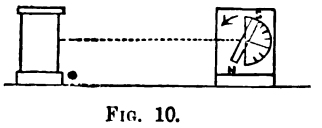

Fig. 10.

simpler form was used. A magnet, N S (Fig. 10), was pivoted so as to move in a vertical plane, and placed directly behind or in front of the galvanometer. The zero position is when the magnet is at right angles to the line joining its centre to the needle, its poles being then equidistant from the latter and neutralising each other. When, however, it is turned in the direction shown by the arrow the effect of the S pole gradually increases, while that of the N pole diminishes till the maximum

Digitized by Google

is reached when the magnet is in the line joining its centre to the needle. By turning in the opposite direction the effect is of course reversed. The force, as in the duplex controller, acting solely at right angles to the needle, has no effect on the time of swing and sensitiveness. Both these forms were calculated in the same way as described for the first controller.

The shunt box as designed and used by the authors was of a new pattern, and by means of it shunts could be instantly put on the galvanometer and the correct compensating resistance thrown in at the same time, the necessity of being able to alter rapidly being caused by any sudden increase or diminution of the current; that of the compensating resistance, by the fact that the external resistance was often small compared to the resistance of the galvanometer, in which case, as is well known, the ordinary shunts are incorrect. Fig. 11 is a diagram of the galvanometer and shunt box. The dotted line shown joining the contact pieces, A *a*, is a brass bar with platinum contacts, pivoted at its centre, and, through the pivot, connected to the terminals T_5, which is joined to T_2 of the galvanometer.

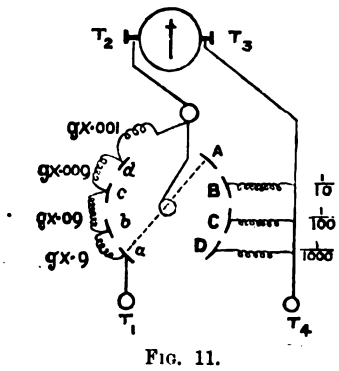

FIG. 11.

With the bar in the position shown the current enters at T_1, passes through the bar straight to the galvanometer and out at T_4, the resistance being g that of galvanometer. When the bar is turned so as to rest on B *b* the current enters at T_1, passes through the resistance marked $g \times \cdot 9$ to the bar, where it divides, part passing through the galvanometer and part through the shunt marked $g \times \frac{1}{9}$, the joint resistance of the galvanometer and shunt being $g \times \cdot 1$, and that of the compensator $g \times \cdot 9$; the total resistance remains $= g$ as before. In the same way, when the bar makes on C *c* the current passes first through $g \times \cdot 9$, then through $g \times \cdot 09$, and then to the bar and through the galvanometer and $\frac{1}{99}$ shunt, the total resistance being $g\,(\cdot 9 + \cdot 09 + \cdot 01) = g$ as before, and when on D *d* the 1,000 shunt is put on, while the resistance is $g\,(\cdot 9 + \cdot 09 + \cdot 009 + \cdot 001) = g$.

The contact piece *d* is joined to T_5 by a resistance of $g \times \cdot 001$; by this means, when the brass bar is not making on any of the contact pieces a resistance of $g\,(\cdot 9 + \cdot 09 + \cdot 009 + \cdot 001)$ —that is a resistance equal to the galvanometer—is thrown into the circuit, which it is often convenient to do.

OLD CABLE STORIES RETOLD.—VII.

BY F. C. WEBB.

(*Continued from page 513, Vol. XIV.*)

THE RED SEA AND INDIA CABLE OF 1859—60.

The shore-end was landed from the "Imperidor" on the 17th January, but was not immediately connected to the main cable, the ship lying with the main cable at bow sheave and shore end astern. On the 19th the ship was still in the same position, and the office fittings were being got into order by Messrs. Buffleb and Meyer, of Messrs. Siemens' staff. On this day the "Cyclops" left with Mr. Forde to arrange the landing place at Hellania (one of the Kooria Mooria Islands), which would form the next station. On the 20th, at night, it came on to blow, and the "Retribution's" anchor began to come home, and the ship to drive. Let go another anchor, and got up steam. By 4 a.m. of 21st blowing half a gale; at 7 a.m. wind veered more to the westward, bringing our stern so near rocks that we weighed one anchor, slipped the other, and steamed out to sea, and in doing so passed so close to rocks that a biscuit could have been thrown ashore. It was a very narrow squeak. On the 22nd, after standing on and off, towards afternoon wind dropped, and at 5 p.m. we came in again. The "Imperatrix" had gone round to Telegraph Bay, as we christened the bay where the ends were landed. The "Imperador" during the gale had swung to her anchor, and dragged the shore end off the beach. This end was landed again by light of blue lights, &c. On the 23rd the "Imperidor" commenced paying out shore end and picking up main cable till the three miles of shore end were payed out, and at 4 p.m. final splice was made, thus completing cable between India and Arabia.

The "Imperatrix" this day landed end of shore end of the Muscat-Kooria Mooria section. On 24th left Muscat in the "Retribution," and the "Imperatrix" began to pay out. Paid out till 11 a.m. (15 miles out), when a stoppage occurred, and the "Imperatrix" made signal, "I must cut cable." We ran down to them. They said they had under-run cable one mile, and would be ready in half an hour. About 4:30 they sent a boat to under-run back again. When about a mile back the boat made a signal, and another boat went to them. It was now dark, so we anchored with a kedge; then weighed and dodged round the "Imperatrix," still at anchor. On 25th, at 0:30 a.m., the "Imperatrix" began paying out. When eight miles more were out (making 23) stopped, and began to haul back by hand. Then she cut cable and buoyed end, and ran back to last night's anchorage, and dredged there. The "Imperidor" arrived from Muscat. Mr. Newall asked commodore also to dredge for cable in the "Retribution." All three ships dredged with boats astern until 8:45 p.m. The "Imperatrix" hooked cable, and made signal with blue lights. On 26th the "Imperatrix" had cut cable, and got part leading to shore over stern. The "Imperidor" picked up isolated section, and at 4 p.m. the "Imperatrix" began paying out, the "Retribution" ahead. At 5:35 got to point where the "Imperatrix" stopped yesterday, viz., 23 miles from Muscat. Going seven knots in about 40 fathoms. On 27th, 4 a.m., passed Ras-el-Had, about 2½ miles from land. On 28th, 2 a.m., abreast of island of Myseera. At 45 minutes past noon the "Retribution's" engines broke down, and she instantly made all sail. The "Imperatrix" made the signal, "Well done, brave old commodore." We concluded this message was composed by the lady on board. Disconnected starboard engine, and by 7 p.m. were steaming with port engine and going seven knots. The "Imperatrix" had passed us and gone on a long way ahead. On 29th got abreast of the "Imperatrix," which ship was brought up seven miles from landing place at Hellania, and was splicing on shore end and was going to pay out at night. On 30th we went into regular anchorage at 9 a.m. At 11:30 a.m. the "Imperatrix" began to pay out shore end and landed it same day.

At Hellania there is a magnificent bluff, higher by some hundred feet than the Rock of Gibraltar. On the island there were about a dozen miserable, half-starved Arabs, who live on fish, which abound. One day the officers of the "Retribution" took the ship's Seine net ashore, and at the first haul got a boat load of fish of very great variety. The doctors were eagerly consulting their books on natural history, and made out some of the species, amongst which was the toad fish, which when rubbed swells into a ball. The huts of the Arabs resemble nothing so much as what schoolboys make when playing at "making houses." They were not more than about 4ft. high, and the walls, enclosing about a space of 7ft. by 7ft. of court yard, were about 1ft. 6in. high. For what purpose these can be constructed I am at a loss to imagine, as I cannot call to mind any animal that could possibly be kept out by them.

The office at Hellania was a tolerably well designed building, in wood, with detached buildings for the staff. A party of Royal Marine Artillery from the "Cyclops" were landed to guard the station, as the Arabs from the main land (about seven miles off) occasionally came across and plundered the unfortunate islanders, carrying off anything of value, and sometimes some of the fair sex.

I was told by Mr. Brunton that I could not test the Kooria

Digitized by Google

Mooria-Muscat section, as the end was buried at Muscat. The arrangements for testing whilst paying out included a clock arrangement which put cable to instrument, insulated it, put it to earth or to battery for a certain number of minutes out of each hour. This arrangement I had used for several years on the Hague cables, it having been suggested by Mr. Latimer Clark, the only difference being that in our case it did not put line to instrument, as we had no clerk at the end at all.

On Feb. 4 the "Imperatrix" landed end of Kooria Mooria-Aden section at 8 p.m. At 2 p.m. we started in "Retribution," and went slowly on towards Aden, but the "Imperidor" and "Imperatrix" did not follow. At sunset we buried a poor boy who died the day before during amputation of the leg, rendered necessary by inflammation of the bone. Laid to for night. On February 5, 8 a.m., "Imperatrix" paying out, with "Imperador" in attendance; at about 10 they came up to us. On 6th passed Ras Furtak. On 7th "Imperatrix" made signal:—"I must cut cable." "Imperatrix" backed astern and hauled in. Told us to go on. She made signal:—"All well." On 8th, 10 a.m., passed Maculla, distant 10 miles; 1:30 p.m., brought up in a sandy bay, 25 miles south of Maculla. "Imperidor" there at anchor, had got boats away, and had weighed buoy on end of cable payed out from Aden months ago; 3 p.m. "Imperatrix" arrived, and brought up ahead of us. She had only a quarter of a mile of cable left in her. She got end of part leading to Aden on board, and spoke to Aden and sent messages, but found defect between ship and Aden, but thought it near Aden. On 9th still at anchor. Sent paddle-box boats to coal "Imperatrix" from "Imperidor." They were testing all day. Distance from Aden about 240 miles. Nobody was allowed to land here, as Mr. Rassam (of Abyssinian fame), who was with us as political agent, pronounced it to be unsafe.

On the 10th in same position. At 8 a.m. the "Imperidor," with Mr. Newall and Mr. Meyer, left to grapple up the cable 20 miles nearer Aden for testing purposes. They cut the cable in the evening, and found the fault in the 20 miles, so buoyed—the end of part leading to Aden—and commenced picking up towards us. On 11th still at same anchorage; the "Imperidor" appeared in sight picking up, and soon brought up near the "Imperatrix," and spliced on some new cable she had on board to the part paid out from Kooria Mooria by the "Imperatrix," which ship being the free one now started off to pick up buoy on end 20 miles off. The "Imperidor" started paying out. We followed and passed, the "Imperidor" stopped short of her distance. We afterwards passed "Imperatrix" at the buoy on end of part leading to Aden. Anchored near her, 45 miles south of Maculla.

On the 12th the "Imperidor" arrived, and made final splice, thus completing the first line of telegraph between India and Aden. We went on for Aden. Passed the Indian Navy ship "Aukland," which saluted the commodor's flag with eleven guns. We were going to return the salute when the key of the magazine could not be found, and there was general silent consternation, for somebody was to blame, and the purser quietly whispered to me, "suppose a Russian frigate was alongside." The key was at last found, and the salute returned, but the "Aukland" was nearly out of sight.

On the 13th we arrived at 8 a.m. at Aden. Found line all right to Kurrachee; but broken down to Suakim. Prof. Gordon came on board, having been laying a cable at Batavia. The "Imperidor" and "Imperatrix" arrived at 11 a.m. On the 14th the "Cordilliere," the French frigate which had been at Muscat, arrived.

A number of salutes were fired, we saluted the Brigadier in charge of Aden, and returned the salute of the French frigate; and whilst this was being thundered forth by the main deck guns we read below our letters from home.

(*To be continued.*)

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company yesterday declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended 31st March last, and payable on the 24th inst. The company's books will be closed from the 17th to 23rd inst., both days inclusive.

IMITATION OF THE PHENOMENA OF ELECTRICITY AND MAGNETISM BY MEANS OF LIQUID OR GASEOUS CURRENTS.*

BY M. C. DECHARME.

I have been engaged for several years in a series of experiments having for their object the imitation, by means of hydrodynamics, of the principal phenomena of electricity and magnetism. I have studied the analogy of these two orders of phenomena successively in their mechanical, physical, chemical, and physiological effects, with a view to obtain new proofs in support of the hypothesis in which the electric movement is considered as the undulatory movement of a fluid (ether or ponderable matter). The following is an abstract of the numerous experiments which I have already made:—

1. MECHANICAL EFFECTS.

Hydro-magnet.—After having adapted to a pipe, alimented by the waters of the town, a disc (Fig. 1, No. 1) (of $0^m{\cdot}05$ to $0^m{\cdot}08$ in diameter) surrounding the aperture of the tube, I found that upon approaching the disc to the bottom plate of a vase, either empty or full of water, it produced a sensible attraction, the energy of which depended upon the force of the current and the breadth of the disc. This attraction does not bring the two surfaces to a point of actual contact, for the reason that the liquid flows to the circumference with small speed; but if the tube be raised the resistance due to the differences of pressure which are exercised upon the exterior surface of the disc and in the intermediary space can be determined. This experiment gives a perfect imitation of an electro-magnet which is active so long as an electric current passes through it, and which becomes inactive on its cessation.

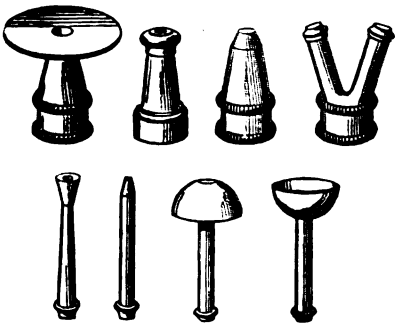

FIG. 1.

If the thick-edged nozzle (Fig. 1, No. 2) be changed for one with sharp edges (Fig. 1, No. 3) the attraction is changed to *repulsion*. These two opposite effects are at their maximum when convergent nozzles are used. It can thus be seen how it is possible to produce, with the two kinds of nozzles, hydro-magnets of opposite poles, the one attractive and the other repulsive.

Hydro-dynamic Vibrations.—In this case the pipe is supplied with a thick-edged nozzle (Fig. 1, No. 2) (of $0^m{\cdot}004$), or with a thin-edged nozzle (of $0^m{\cdot}001$) (No. 3). If it be lifted a little, in order to induce the movement, and then abandoned to itself, it sets up a number of vertical vibrations sufficiently rapid to produce a sound (la_1). If the tube be pressed the vibratory speed is augmented.

This effect is analogous to that of an electro-magnet under the influence of an automatically interrupted electric current, as in the case, for instance, of the coils of an electrical bell in full action. If now the vibrating tube (Fig. 2) be taken in the hand, it seems in every way to resemble a true electro-magnet, so rapid and so strong are the successive effects of attraction and repulsion. They are exactly similar to those of magnetisation and demagnetisation, for the instantaneity of action and increase of energy are in accordance with the diminution of the distance. This experiment not only gives an abstract imitation of electro-magnetic phenomena, but is an effective realisation of the movements produced by electro-

* From the *Journal de Physique*.

Digitized by Google

magnets under the influence of currents regularly interrupted. They are, in my opinion, susceptible at the same time of receiving dynamic applications. It is easy in point of fact to imagine the mechanical arrangements which would convert the vibrating tube into a small high speed motor, a meter, or an interrupter.

Hydro-induction.—The fundamental thing which is the cause of the vibrations in the preceding experiment is that which is produced in the tube at the moment of the *interruption* or of the *passage* of the liquid current. At the moment when the tap which gave passage to the liquid jet was *opened suddenly* there could be felt in the tube held in the hand a pronounced movement of *recoil*, and when the tap was *closed rapidly* a contrary movement, which tended to carry the tube *forward* was noticeable. These effects are analogous, the first to that of the reaction of a car, the second to the blow of a hydraulic ram, produced by the sudden stoppage of the long interior column of liquid. In comparing the liquid current to a voltaic *inducing* current, and the envelope, the tube, to the wire *induced*, and surrounding the inducing wire, the phenomena which have been described are analogous to those that an electric current alternately opened and closed produces in the induced wire. Again, the hydro-dynamic movements are *instantaneous*, as with induced currents—that is to say they are manifested at the moment of the passage, or of the interruption of the current. During its entire duration there is no dynamic effect. It is known that when an inducing electric current *begins*, *increases*, *diminishes*, or *ceases*, it originates in the wire induced a current *inverse*, *increasing*, *decreasing*, or *direct*. It is absolutely the same with liquid currents, a fact which is by no means difficult to verify.

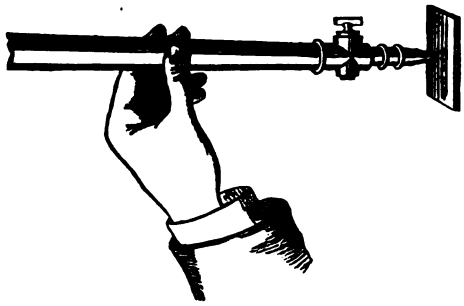

FIG. 2.

Reciprocal Action of Currents.—For these experiments I have adopted the following arrangements :—A branch, such as Y (Fig. 1, No. 4), is screwed upon the waterspout and carries two india rubber tubes of equal dimensions, at the extremities of which are adapted nozzles of diverse forms, cylindrical, conical, hemispherical, &c. For the liquid currents issuing (in the air or in the water) by two tubes *without nozzles*, currents parallel in the same or in a contrary direction, angular currents, &c., I have found the same laws as for electric currents. But with tubes provided with thick-edged nozzles or with discs, one at least of the tubes being mobile (Fig. 1, No. 5), the results are entirely different; two currents of contrary direction and directly opposed to each other are attracted (in the water), when the distance which separates the openings is not more than $0^m \cdot 01$ approximately, and this attraction increases rapidly, accordingly as the distance diminishes. If the discs are removed a considerable resistance and a number of strong vibrations can be felt, more especially when convergent nozzles are used. If the nozzles are disposed angularly or excentrically an *axial force* restores the currents to parallelism and to the coincidence of their axes. With nozzles with slender or sharp edges (Fig. 1, No. 6) there is always *repulsion*, *axial direction*, and *vibrations*. If the currents (directly opposed to each other) be diverted from their position of equilibrium, that which is mobile oscillates in the same manner as the needle of a compass when under the influence of a bar magnet. The more the nozzles are soft and the tubes flexible, the more the oscillatory phenomena are apparent. Nozzles, with curved edges, concave or convex combined two and two with the preceding, have given varied effects, among which we may mention the following :—When a *concave* nozzle (Fig. 1, No. 7), was adjusted to one of the tubes of the branch, and a convex nozzle (Fig. 1, No. 8) to the other tube, they produced a *strong attraction*, which was sensible at a distance of $0^m \cdot 05$. The axial direction is equally pronounced with this system.

Repulsion of the Consecutive parts of the same Current.—In order to demonstrate that the consecutive parts of the same current repulsed each other, I devised an experiment which is simple and demonstrative. A small india rubber tube of great flexibility (of $0^m \cdot 12$ to $0^m \cdot 25$ in length, $0^m \cdot 004$ to $0^m \cdot 005$ interior diameter, and $0^m \cdot 0015$ to $0^m \cdot 002$ thick) was adapted directly to a tube alimented by the waters of the town. When a current of water flowed by the small tube, which was held in the hand, there could be felt a strong traction of the tube, a distinct and pronounced *recoil*. In order to determine the value of this force I attached to the free end of the small tube, which was held vertically, a wire carrying a weight, and found that the reaction was capable of lifting 140 grains, or with perfect ease a weight of 100 grains. On releasing the small tube it twisted in different ways and threw water in all directions. Placed in the liquid it wriggled in a most lively manner, and had a tendency to press against the bottom and sides of a vase. The tube, reduced to $0^m \cdot 10$ in length, vibrated spontaneously with great quickness. All these effects are evidently due to the repulsion of the consecutive parts of the liquid current; they thoroughly demonstrate the existence of this reaction, and give the measure of its energy.

(To be continued.)

NOTICES OF BOOKS.

Anleitung zur Errichtung und Instandhaltung oberirdischer Telegraphen-und Telephon-Linien aus Lazare Weiller's Patent Silicium-Bronze-Draht. By T. B. GRIEF. [L. W. Seidel v. Sohn, Vienna.]

In this handy little book the author records a number of facts regarding the mechanical, chemical, and electrical qualities of Weiller's silicium bronze, and the experience of practical electricians in laying telegraph and telephone lines of this material.

The copper used in the manufacture of these wires is that known under the name of "Lake Superior," and is specially pure. The conductivity of silicon copper wire is said to be equal to that of silver, and the author recommends the use of it for submarine and underground cables, and for electrical transmission of power. For overhead lines silicon bronze wires are preferable, partly on account of their greater tensile strength, and partly because they withstand for an almost unlimited time the oxidising influence of the atmosphere. A slight coating of oxide is indeed formed, but this does not extend into the body of the wire, and it acts as a kind of insulator. As in all similar alloys, high conductivity and high tensile strain are to some extent antagonistic, but the latest brands of silicon bronze seem to fulfil both requirements far better than phosphor-bronze or manganese bronze. Thus we see from a curve, giving tensile strain as abscissæ and conductivity as ordinates, that a conductivity of 100 per cent. can be obtained with a material whose tensile resistance is 30 tons per square inch, or 80 per cent. at 37 tons, 40 per cent. at 53 tons, and 20 per cent. at 75 tons. From these figures it will be seen that with a breaking strain equal to that of ordinary iron wire a silicon bronze wire has about the same conductivity as pure copper.

Four principal qualities are made and used for the purposes specified in the annexed Table A.

Extended tables are given for each brand, designed to facilitate the choice of wire for each special purpose, and to avoid the trouble of long calculations. These we cannot, however, reproduce for want of space. An interesting table, com-

Digitized by Google

paring the weight of steel and iron wires with silicon bronze wires electrically equivalent to them, is also given, of which Table B is an abstract.

On account of the reduced weight of silicon bronze, as compared with iron, and its greater tensile strain, a considerable saving can be effected in long telegraph lines. Not only can lighter poles be employed, but the increase of span results in a considerable reduction in their number, and the cost of carriage and erection, both for wire and poles, is also materially lessened. From the estimate given by the author in detail, we note that a line of 1,000 miles, complete and ready for traffic, costs in iron about £32,000, and in silicon bronze about £22,000. Such calculations are, however, sometimes misleading, and to put the matter on a practical basis the author should have made his estimate, not for a single line in which the cost of poles forms a very serious item of the total cost, but for twenty or more lines carried on the same poles.

TABLE A.

Brand.	Conductivity in comparison to pure copper.	Breaking strain. Tons per square inch.	Specially suitable for
A	97 % to 99 %	28 to 30	Aerial telegraph lines, submarine cables, wires and cables for electric lighting and transmission of power.
B	80 % to 84 %	35 to 37	Long telegraph lines and long spans.
Extra A	42 % to 44 %	51 to 55	Short telegraph and long telephone lines, military telegraphs and temporary lines.
Special B	20 % to 22 %	71 to 74	Very long spans, wire ropes, sounding lines for great depth.

TABLE B.

Material hitherto used.			Equivalent Silicon Bronze Wire.	
Quality.	Diameter in Mils.	Weight per Mile in lbs.	Diameter in Mils.	Weight per Mile in lbs.
Cast Steel	7·8	95·5	3·9	24·7
Steel	13·8	265·0	5·9	55·8
Iron	19·6	552·0	7·9	95·5

The book contains very minute instructions for the putting up of lines, and a description, with illustrations, of the tools required. English electricians will probably be astonished to find that Herr Grief gives instructions how spirit of salt must be used when soldering joints. He does not absolutely condemn its use, but merely mentions resin as a somewhat safer material. We should have thought it by far the best not to tolerate the use of killed salts under any circumstances whatever.

The attachment of lines to the insulators, the different forms of the latter, as also poles and other supports for a large number of wires, are fully treated. The chapters on lightning conductors and on the precautions to be used to avoid a singing noise in the wires being transmitted to the building might with advantage have been enlarged. On induction nothing at all is said. The book is well printed, and contains a good index.

ATMOSPHERIC ELECTRICITY.—Mr. L. Palmieri has found that the electricity is always positive when, within a circle of 140 kilometres in radius of the place of observation, neither rain, snow, or hail is falling. If negative electricity is observed with a clear sky, downfall at some little distance may be inferred.

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

Prof. Tyndall, in his sixth lecture, reminded his audience that in the previous lecture he touched on the subject of pyro-electricity and on the subject of thermo-electricity. As the names indicated they were both connected with heat—electricity developed by heat. Pyro-electricity was produced when crystals which had been heated were becoming cool. Tourmaline was an eminent example of these crystals. They found one electricity at one end of the crystal and another, an opposite electricity, at the other end. This pyro-electricity was developed upon insulators—crystals which were insulated—non-conductors. Thermo-electricity, on the other hand, was developed by heating the junction of two different metals. Bismuth and antimony were eminent examples of this. If they were soldered together and brought into contact there was an electrical current. Thermo-electricity was discovered by Seebeck, of Berlin, in 1826. Five years rolled by, and perhaps a discovery which quite ranked with the discovery of the voltaic pile was made within the walls where they were then assembled. In November, 1831, Faraday communicated an ever-memorable paper on induced currents to the Royal Society. Faraday took a round piece of wood, such as that which he (the lecturer) then held, and rolled around it a coil of copper wire over-spun with cotton. He (the lecturer) explained that in the example before them there was a coil within next to the wood, of which these two were the ends, and there was another coil coiled round that, and separated from it, in Faraday's case—not only separated from it by the over-spinning of the wire, but separated the one coil from the other by a mass of paper, over which the voltaic current which Faraday used could not pass. How Faraday came to think of the experiment he could not tell. He remembered once an eminent German saying to him "he smelt it." Faraday had an instinct towards the secrets of nature in putting things together so as to ask nature the proper question and obtain the proper answer. He made this experiment. He connected the two ends of the wire forming the interior coil with a voltaic battery, and he connected the two ends of the outer coil with a galvanometer. He knew that if he got any electric current he would be able to detect it in the magnetic needle. He made various experiments, and it was on the point of eluding him, and it might have eluded a man of less skill, observation, and power than Faraday. But he expected some permanent effect to be produced. His mind was awake and his eyes open to every action of the apparatus, and he noticed at the moment when he followed the circuit which communicated with his battery with the inner coil, the galvanometer connected with the outer coil made a little move. He watched it, and found that it was always in the same direction, and that it was only a momentary shock of the needle which was thus produced. He interrupted the circuit, and saw the current in the opposite direction. He also made this experiment :—There was a voltaic coil (indicating it) covered with copper wire, and varnished with shellac. Having placed it in a position described, he said that they had now a current passing from the battery through this coil. If he allowed his hand to rest on the coil any time he would know that a current was passing. The action was a very small one, and they would have to pay considerable attention to the needle. [Experiment.] They found a little tick—just what Faraday experienced. He brought one coil on the other, and caused the coil through which the current flowed to approach the coil disconnected from the battery. He now brought it down [experiment], and they would observe the small motion of the needle. That was what Faraday observed, and they would see that it was only a momentary action. He would now lift one coil from the other, and they would then observe a motion of the needle in the opposite direction, as Faraday noticed it. [Experiment.] They would remember what he said on a former occasion about the smallness of the germs from which great scientific discoveries arose, and also great practical developments. It was from the little seedling which they had just seen that the electric light had been developed. The incandescent and arc lights and all the companies formed in connection with them had been founded on that little discovery of Faraday; and Faraday himself, who made this discovery, never obtained a shilling by it. He (the lecturer) would not think of saying anything disparaging of those who brought such discoveries to practical use, but he again maintained that men like Faraday were the discoverers, and that it was the office of practical men to develop the discoveries made by such investigations. Mr. Cotterell had placed in his hand a common coil of wire, just as it had come from the instrument maker, a coil of covered copper wire. He held that coil and before him there was a magnet. In his last lecture he spoke of the relationship between electricity and magnetism. He took that magnet, and, putting its pole through the coil, produced a current in one direction; taking it away produced a current in the other direction. He would now make a little experiment in a manner which he thought would cling to their

Digitized by Google

memories. The direction of the current depended on the pole of the magnet thrust through. One pole produced a deflection in one direction, and the opposite pole produced a deflection in the other direction. [Experiment.] There was another point developed by Faraday. He used a ring of iron. He found that if, instead of coiling his two coils of wire round a piece of wood, he coiled one of them round a coil of iron and connected that coil with a magnet or battery, that coil within the coil became highly magnetised. He would now ask Mr. Cotterell to show him certain lines—which perhaps every boy and girl present had seen—to which Faraday attached supreme importance. He made some beautiful experiments with the assistance of the screen, illustrating what Faraday called the lines of magnetic force, which, he observed, were very well known before Faraday's time, and called magnetic curves. Proceeding, he reminded them that the earth was a magnet. The space around a magnet was a magnetic field—that was to say, a region within which magnetic force exercised the needle. He was going to say that we all lived in a magnetic needle, and were all permeated by these lines of magnetic force. If he could scatter iron filings in that room, and they were not attracted by the earth—if they did not fall to the earth—they would arrange themselves in lines such as he would now point out. Displaying a wheel, he observed that it was made of coils of copper wire. He spun it round, remarking that he tried to make the axis of the spinning coincide with the earth's line of force. If he turned the wheel in one way they would see that there was next to no action on the needle, but if he turned it the other way they would observe that the needle went obediently and would go to 90 degrees. Faraday followed through all his life these lines of force, which led him to all his great discoveries in electricity and magnetism. The experiments which they had just seen should impress them with the extreme importance of the action of those lines of force. He had an instrument there which would enable him to describe to them exactly the experiment made by Faraday. They saw that he held one coil—the interior coil—and there was the exterior coil, and that exterior coil he would connect with the galvanometer. He would attach the galvanometer to the outer coil, and he would now pass a current from a battery of ten cells. He had connected one coil with the battery and the other with the galvanometer. [Experiment.] There was, as they saw, the same motion, small, but very perceptible. If he took off the current the needle went back. He repeated the experiment with a little more current from the battery. He then called attention to an instrument which he described as "the beautiful reflecting galvanometer of Sir William Thomson," which he explained, and with the assistance of which he made some instructive and pleasing experiments. It had been his wish to show them how easy it was to produce these induced currents. By a few small experiments they had had laid bare the whole origin of this magneto-electricity, or discoveries of induced currents by Faraday. Faraday, with the prophetic vision which belonged to him, said "I am more anxious now to discover new facts and new principles, however small the facts may be, feeling perfectly sure that those facts will get their due development hereafter." It was prophetic, for, as he (the lecturer) had said, all that they now saw in connection with the electric light had come from the small germ which they had seen. Soon after Faraday's discovery it was sought to make machines to utilise these induced currents. He then exhibited a machine, which he said had been made for nearly half a century, and with which he made an experiment. They were indebted to Mr. Wilde, of Manchester, who made a great step forward in this direction. With the assistance of Mr. Wilde's machine and Siemens's armature he made some interesting experiments. He would now pass to another matter, and this was the only step made since Faraday's discovery. It was announced simultaneously by the late Sir W. Siemens and the late Sir Charles Wheatstone, and their discovery was brought before the Royal Society on the same night. He explained the working of the machine, and showed how, by a series of actions between coil and coil, the magnetism was exalted to an enormous extent. He had now again to refer to the influence of resistance in producing heating effects outside the circuit. He exhibited a wire composed of two metals—silver and platinum—through which he intended to send the self-same current, and they would observe that the wire would be heated in spaces, and that it was not uniformly heated throughout. The same result was not produced throughout, in consequence of the resistance of the brighter metal. He next directed attention to a bulb from which the air was excluded, and showed some carbon filaments, which he said were used in incandescent electric lamps. Having shown one of Edison's and one of Swan's lamps, the lecturer stated that they had subsequently had the aid of Mr. Crompton, who had placed the lamps round the gallery of the theatre (and with which the theatre was lighted, whenever necessary, in a most effectual manner). He next called attention to the Gülcher lamp, with which he showed a beautiful arc light, explaining how the two carbon points were consumed as the electric current passed through. The carbons, he stated, would burn for eight hours without renewal. Various other gentlemen had helped him in the delivery of his lectures, and he was specially indebted to the Messrs. Siemens, who were represented now by Mr. Alexander Siemens, who had provided him with a dynamo, which was downstairs, and which generated the powerful currents, effects of which they had seen. Having cut through a piece of wood by a circular saw which was set in motion, he thus showed another use to which electricity could be applied.

Prof. Tyndall, who in the course of the lectures had been warmly applauded, here announced that he had come to the end of his task, which had afforded him very great pleasure. He thanked them for the great attention which they had paid, and he asked them not to thank him only, but also Mr. Cotterell, who had afforded him such great assistance. As promised by Prof. Tyndall in his prexious lecture, a copy of the work which he then mentioned—"Notes of a Course of Seven Lectures on Electrical Phenomena and Theories," delivered by him in April and June, 1870—was distributed to many who had attended the course.

RELATION BETWEEN THE ELECTROMOTIVE FORCE OF A DANIELL CELL AND THE STRENGTH OF THE ZINC SULPHATE SOLUTION.*

BY H. S. CARHART.

The investigation here described was carried out in the physical laboratory of the University of Berlin in the spring of 1882, and was undertaken with a view to ascertain whether the variation in the strength of the zinc sulphate solution surrounding the zinc plate of a Daniell cell affected the electromotive force, and to what extent.

It is well known that different experimenters have found different values of the electromotive force of a Daniell element. Thus Sir William Thomson found a value of 1·122 volt; Latimer Clark, 1·11; Kohlrausch, 1·138.† These different results may be partly due to difference of method; but it is easy to ascertain that slight changes in the condition of the plates or in the concentration of the solutions modify the value of the electromotive force to an appreciable extent. The method employed in this investigation was essentially the compensation method of Poggendorff.‡ The two poles of the battery A, the electromotive force of which

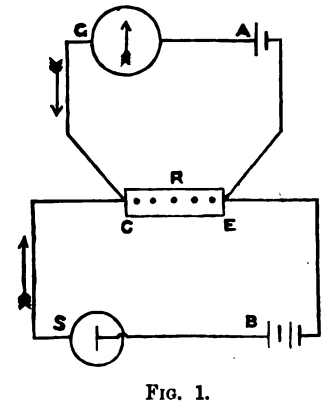

FIG. 1.

is required, are connected with two points, C E, of a second circuit containing a battery, B, of higher electromotive force than A. The resistance between C and E is then varied by means of the rheostat R, till no current flows through the circuit of battery A. The difference of potential between the points C and E is then the electromotive force to be measured. By Ohm's law, the product of the resistance inserted between C and E and the strength of the current in the main circuit equals the difference of potential between the two points, or the electromotive force of A.

The current was measured by a silver voltameter, S, with pure nitrate of silver. The resistance employed at R was in Siemens units. The deposition of silver was continued for ten minutes; the cup was then washed with great care, dried in a hot air chamber, and weighed after cooling, fractions of milligrams being obtained by observing the swing of the pointer.

The Daniell cell consisted of a U tube of the form employed by Kohlrausch in measuring the resistance of electrolytes,§ the bend of the tube being much smaller than the two branches. The lower portion was first filled with a saturated solution of pure zinc sulphate; saturated copper sulphate was then added to one branch, and a percentage solution of zinc sulphate to the other. The sulphates were so added that the surface of separation between two solutions in contact was quite clear and sharp. This was effected by first placing a small disc of cardboard on the surface of the liquid in the tube, and then carefully pouring the other

liquid on it from a pipette. No sensible diffusion took place during the time required to make the observations.

The galvanometer in the circuit of A was a sensitive one and was observed with a telescope and scale at a distance of about two metres. After a little experience a balance was readily obtained by the greater or less immersion of the silver plate in the nitrate of silver solution of the voltameter; and it was tested from time to time during the deposition of the silver and corrected if necessary. The galvanometer never showed a deflection of more than a few scale parts—perhaps five of the millimetre divisions. The electromotive force of A was thus measured with minimum liability to polarisation, and by a method entirely independent of the internal resistance of the cell. The only resistance required is that between C and E, and this can easily be measured by means of a rheostat.

The temperature of the rheostat and of the cell was observed at every trial. The extreme limits of variation in the temperature of the cell was 3° ·2 C.

The table exhibits the results; but the final reduction, as shown in the last column, was not made till after the recent report of the Paris commission on the legal ohm, and the publication of the results of Lord Rayleigh's experiments with the silver voltameter.* The values of the electromotive force, given in the column next to the last in arbitrary units, were reduced to volts as follows:—

Per cent of $ZnSO_4$	Temp. of R'eostat.	Resist. in Siemens Units.	Silver deposited in one min.	Prod. of resist. & silver.	Cor'd. for temp. of rheostat.	Mean value of product.	E.M.F. in volts.
			mgs.

3	18	11	7·339	80·729	80·664	80·584	1·133
	19·5	12	6·710	80·520	80·504		
5	17·8	11	7·423	81·653	81·581	81·216	1·142
	17·3	11	7·358	80·938	80·851		
7·5	17·3	11	7·239	79·632	79·546	79·620	1·120
	18·3	11	7 250	79·750	79·694		
10	17	11	7·224	79·464	79·369	79·490	1·118
	19·3	11	7·239	79·634	79·612		
15	20	11	7·219	79·409	79·409	79·305	1·115
	18·3	11	7·205	79·255	79·201		
20	17·3	11	7·170	78·870	78·785	79·008	1·111
	17·5	11	7·210	79·310	79·231		
25	16·3	11	7·199	79·189	79·072	78·997	1·111
	16 6	11	7·184	79·030	78·923		
						Mean	1·122

The ratio of the Siemens unit to the congress or legal ohm is 100 to 106, or, 50 to 53. According to Lord Rayleigh a current of one ampere deposits 4·025 gms. of silver in an hour, or 67·08 mgs. a minute. Therefore if C, R, and E represent current strength, resistance, and electromotive force in amperes, ohms, and volts, and e the electromotive force in the arbitrary unit of the table, we have the following equation,

$$\left(R.\frac{53}{50}\right)(C \times 67{\cdot}08) = e\,;$$

$$\text{whence } R\,C = \frac{e}{\frac{53}{50} \times 67{\cdot}08} = \frac{e}{71{\cdot}105} = E.$$

It is only necessary then to divide the quantities in column seven by 71·105 to reduce them to volts.

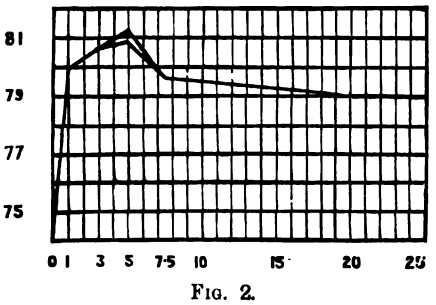

FIG. 2.

The method employed is amply sustained by the results obtained with a Latimer Clark standard cell. Two trials gave the same result. I give only one of them.

Time of deposition of silver	10 min.
Resistance between C and D	20 S. U.
Temperature of rheostat	19°
,, Clark's cell	18°
Weight of silver cup after deposition	26·1963 gms.
,, ,, before ,,	26·1453 ,,
Silver deposited in 10 min	0·051 ,,
,, ,, 1 min	5·1 mgs.

$5{\cdot}1 \times 20 = 102 = e.$ $\qquad 102 \div 71{\cdot}105 = 1{\cdot}434 = E.$

The electromotive force of a Clark element is therefore 1·434 volts, the exact value given by Lord Rayleigh* instead of the formerly accepted value of 1·457 volts.

The mean of all the values of the electromotive force in the last column of the table is 1·122, which is the value obtained by Sir William Thomson by the electrostatic method, if the velocity expressing the ratio between the electrostatic and electro-magnetic units be taken as 3×10^{10}.

In Fig. 2 the results of the investigation are set forth graphically; the ordinates represent the excess of the quantities in Column 7 of the table above 74, the value obtained with distilled water; while the corresponding abscissæ denote percentages of zinc sulphate. It will be observed that little variation in the value of the electromotive force occurs after reaching ten per cent. of zinc sulphate, and that the maximum value appears to be at about five per cent. I have some reasons for doubting the accuracy of the larger of the two values found with the five per cent. solution. If the smaller value alone is employed the points laid off may be connected by nearly a plane curve.

It thus appears that the variation in the concentration of the zinc sulphate solution is sufficient to account for the larger part of the discrepancy between the results obtained by different experimenters in measuring the electromotive force of a Daniell cell. It would therefore seem desirable that a standard Daniell element should be so constructed as to admit of employing a zinc sulphate solution of known concentration. The form proposed by Prof. G. F. Barker,† in which the solutions are satuarated, appears to meet the requirements in this respect.

TECHNOLOGICAL EXAMINATIONS, 1885.—EXAMINER, PROF. W. E. AYRTON, F.R.S.

22B. Electric Lighting and Transmission of Power.

INSTRUCTIONS.—This examination is for the purpose of ascertaining whether the candidate has intelligently studied the methods of constructing and using the machinery employed in the production and transmission of electric power, and whether he has endeavoured to ascertain the scientific reasons underlying the processes adopted. The candidate must confine himself to one grade only, the Ordinary or Honours, and must state at the top of his paper of answers the grade he has selected. He must not answer questions in more than one grade. If he has already passed in this subject, in the first class of the Ordinary Grade, he must select his questions from those of the Honours Grade. The number of the question must be placed before the answer in the worked paper. Three hours allowed for this paper.

ORDINARY GRADE.—[Candidates are not to answer more than two out of the first three questions, and not more than seven questions altogether.]

1. Explain exactly what is meant by saying the electric resistance of a given wire is constant for the same temperature, and independent of the current passing through the wire.

2. A battery is sending a current through a wire. If this wire be gradually made shorter and shorter, describe what changes will take place (1) in the current, (2) in the potential difference at the terminals of the battery, and (3) in its electromotive force.

3. Define fully an ampere, an ohm, and a volt. What current will 15 cells, each having an E.M.F. of 1·07 volt and an internal resistance of 0·7 ohm, send through an electro-magnet having 28 ohms resistance, when the electro-magnet is shunted with a wire having 7 ohms resistance?

4. Why is it necessarily more costly to produce a given amount of light with incandescent lamps, as at present made, than with arc lamps?

5. Describe, with detailed sketches, some form of arc lamp with apparatus for automatically maintaining a fixed length of the arc.

6. What is meant by a compound wound dynamo? Describe, with detailed sketches, some form of compound wound dynamo.

7. Describe, with sketches, some form of commercial instrument for measuring strong currents, and mention what conditions ought to be fulfilled by such an instrument.

8. Edison glow lamps requiring 108 volts potential difference, and 0·72 of an ampere each, are required to be fed by accumulators, each having 2·1 volts E.M.F., and 0·0017 ohm resistance. What is the least number of such accumulators arranged in series that must be employed to feed 200 of these lamps in parallel?

9. Explain, with sketches, the instruments as well as their arrangements that you would employ to measure the "efficiency" of an arc lamp. Give examples of the sort of result you would expect to obtain.

10. Why cannot the direction of rotation of an electric motor be reversed by reversing the direction of the current passing through it? Describe, in detail, the methods by means of which the direction of rotation may be reversed.

11. Why are low resistance galvanometers used to measure large currents, whereas high resistance galvanometers are employed to measure large differences of potential? If a high resistance galvanometer arranged to measure the difference of potential between two points A and B in an electric circuit were replaced with a low resistance galvanometer, but without any other change being made in the arrangement, what would now be measured by this low resistance galvanometer?

Digitized by Google

12. What is meant by the "lead" in the brushes of a dynamo? Explain fully why sparking at the brushes occurs if the lead is wrong.

13. The potential difference at the terminals of a series dynamo running at a constant speed first increases, and then diminishes, if the external resistance be first large and then be steadily diminished. Give an explanation of this, graphically if you can, employing the characteristic curve of the dynamo.

14. Describe, by means of detailed sketches, the mode of constructing and connecting up (1) a separately excited, (2) a series, (3) a shunt dynamo.

15. What is a "watt?" Give a drawing and description of a watt meter.

HONOURS GRADE.—[Candidates are not to answer more than one out of the first three questions, and not more than seven altogether.]

1. Explain exactly what is meant by saying that the electric resistance of a given wire is constant for the same temperature and independent of the current passing through the wire.

2. A battery is sending a current through a wire. If this wire be gradually made shorter and shorter, describe what changes will take place (1) in the current, (2) in the potential difference at the terminals of the battery, and (3) in its electromotive force.

3. Define fully an ampere, an ohm, and a volt. What current will 15 cells, each having an E.M.F. of 1·07 volt and an internal resistance of 0·7 ohm, send through an electro-magnet having 28 ohms resistance, when the electro-magnet is shunted with a wire having 7 ohms resistance?

4. Describe, with sketches, the mode of constructing and connecting up the wires in an alternate current motor.

5. How should two alternate current generators be coupled up so that the currents produced by the two generators may assist one another? Explain fully why the method you describe fulfils its object.

6. What sort of error would be produced by using a high resistance galvanometer to measure an alternating difference of potential? In what way can an alternating potential difference be measured accurately?

7. It is found that with a magneto-electric machine the E.M.F. is not absolutely constant for a given speed, but varies with the current produced. Why is this, and how can this variation of E.M.F. be reduced to a minimum?

8. What are the advantages and disadvantages of using secondary batteries? Show how a secondary battery should be attached to an electric light circuit fed with a shunt dynamo in order to steady the light.

9. In the last question calculate what may be the greatest resistance of a secondary battery compared with the resistance of the other portions of the circuit, so that the potential difference at the terminals of the lamp circuit shall not vary by more than 1 per cent. when the E.M.F. of the dynamo increases by 8 per cent.

10. Judging from the experiments and calculations that have been hitherto made, in what cases would you recommend the employment of water transmission, and in what cases electric transmission of power?

11. What are the exact experiments that should be made with an incandescent lamp in order to determine its commercial value relatively to that of other incandescent lamps?

12. You are required to design and fit an electro-motor to a tramcar. Describe the advantages and disadvantages of the following three methods:—(1) A rapidly-turning motor attached to the ordinary tramcar wheels with some speed-reducing gear, (2) a rapidly-turning motor attached to a small driving wheel running on the rail without speed-reducing gear, (3) a motor attached directly to the ordinary tramcar wheels, and only turning as fast as they ordinarily do. Select the one of the methods that you consider the best, and give sketches of the exact way in which you would carry it out.

13. Give detailed drawings of a non-sparking key.

14. Draw a curve connecting potential difference at the terminals of a shunt dynamo with the current flowing in the external circuit, and show how you can graphically construct from this a curve connecting the total electromotive force in the dynamo with the total current flowing through the armature.

15. What are the advantages and what the disadvantages of feeding the incandescent lamps in a district in series?

16. Show why the Board of Trade regulation requiring electric light to be supplied to a house within a given distance of the mains, and which must be charged for a fixed rate per Board of Trade unit, and, independently of the time per night that the current is required, cannot work fairly both in the interests of the supplier and consumer.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The meeting of this society on Thursday, 28th May, Mr. Spagnioletti, the president, in the chair, was occupied with two papers relating to certain recent installations of electric lighting. The one by Mr. B. J. FARQUHARSON, member, set forth the results of the experimental trial on board H.M.S. "Colossus;" the other, a descriptive account of the lighting of the works for the construction of the new Forth Bridge, was by Mr. JAMES N. SHOOLBRED, B.A., member. Mr. Farquharson, explained that the fitting up of the "Colossus" with incandescent lamps was by order of the Admiralty for the purposes of ascertaining the expense of this mode of lighting compared with that of the oil lamps ordinarily employed in H.M. Navy. There was nothing novel in the arrangements, but the results were highly satisfactory and encouraging for this class of electric lighting enterprise. Full details were given of the distribution of the lamps (400 in number) over the various parts of the ship, and the hours during which the several groups were kept burning—some day and night continuously, others for a few hours each evening. The trial extended over seven consecutive days and nights, a period considered sufficiently long to determine the question to be decided. The balance of saving proved to be at the rate of £1,852. 14s. 8d. per annum compared with the cost of maintaining oil lamps, which latter of course included the charge for lamp trimmers, &c. In this and other respects the trial had given such satisfaction to the Lords of the Admiralty that their lordships had just issued an order for the fitting-up of all the great war ships in a similar manner with electric lamps. Detailed and tabulated summaries of the seven days' steaming of electric engines, and the average readings of the dynamos were furnished with Mr. Farquharson's paper, but they presented no features of exceptional or novel character.

Mr. SHOOLBRED'S paper described very carefully the important installation at the Forth Bridge works, which began in 1883 and are still in progress. The bridge has a total length of about a mile and a half, and the works on land where the materials of the bridge are constructed before being placed in position extend over another half mile or more. The special peculiarities of the installation are that much of the lighting has to move with the constantly shifting work, and that a great deal of the work is done under water. Both arc and incandescent lamps are employed, sometimes running as long as 700 hours at a stretch. It was also necessary to give confidence to the workmen employed, so that no fears need be apprehended of accident from touching the wires. 120 volts is, therefore, the maximum power used. Messrs. Siemens have the south side of the bridge under their care, the north portion being lighted by Messrs. Crompton. They have got through the severities of two winters without any hitch or accident, and the efficiency of the lighting has been warmly acknowledged. Some of the lights were a mile and a half distant from the engines; yet, on the whole, the losses by distribution are less than the generally accepted average, especially in the work sheds, where the temperature is highly favourable to economic supply. Owing to the sea spray which fills the air in the neighbourhood of the bridge, the relative durability of india rubber and gutta percha as insulators had been tested under these conditions, and it was found that the former very soon became useless, solid gutta percha being better; but naked copper wires are frequently used, and the corrosion is found to be very slight. As to the duration of the Swan lamps employed in this installation, the average for the first half year was 404 hours, for the year following it rose to 700, whilst for the present half year not yet expired—during which the latest improved form of lamps has been introduced as the older ones gave in—the average life is 1,200 hours.

The discussion which followed was confined chiefly to the lighting of the "Colossus." Mr. CROMPTON pointed out that the conditions of all such trials are highly unfavourable in one respect, seeing that low pressure steam is the rule on board H.M. steamships, the least economical power for electric lighting. Mr. ALEX. SIEMENS also pointed out that the loss of lamps in this experiment (no less than 60) was altogether unprecedented. Probably a bad lot of lamps had been supplied to the undertakers. At the Savoy Theatre there were quite a large number of lamps which had been burning from the very first; and a P. and O. boat making the journey to and from New Zealand had returned with only one breakage. The secret of prolonging the life of these lamps was to always run them well below their power of endurance. Professor Ayrton, Dr. Fleming, and Mr. Swinburne also took part in the discussion.

THE ERRORS IN INDICATOR DIAGRAMS.

At the ordinary meeting of the Institution of Civil Engineers, on the 19th ult., a paper was read "On the Theory of the Indicator and the Errors in Indicator Diagrams," by Professor O. Reynolds, M.A., LL.D., F.R.S., M. Inst. C.E.

The object of the paper was to define the causes and extent of the disturbances in indicator diagrams. The theory, as given, had been taught for several years in Owens College; but the publication had been deferred to enable an extensive series of experiments to be made. These experiments had now been carried out by Mr. A. W. Brightmore, Stud. Inst. C.E., late Berkeley Fellow in Owens College. In the first place it was shown that there were five principal causes of disturbance, namely, the inertia of the piston of the indicator and its attached weights; the friction of the pencil on the paper, and its attached mechanism; varying action of the spring; inertia of the drum; friction of the drum.

The effect of the inertia of the pencil and its attached mechanism presented a mathematical problem, by the solution of which it was shown that there were two disturbances from this cause; one, a general enlargement of the mean indicated pressure, depending on the weight of the moving parts of the indicator, the stiffness of the spring, and the square of the speed. The other disturbance was a vibration of the pencil. Every indicator piston vibrated when disturbed, so that the period of vibration depended on the stiffness of the spring.

The error which these oscillations caused in the area of the diagram depended on their magnitude, and, to a greater extent, on the smallness of the number in a revolution. But the evil of these oscillations was not so much an effect on the area as in the disfigurement and the confusion they produced in the diagram. So long as there were 30 of these oscillations in a cycle, the necessary fluid friction of the indicator piston would so far reduce them as to render a fair diagram possible, but when the number was as low as 10 it was all the pencil could do to prevent them upsetting the diagram.

The friction arising from the pressure of the pencil always acted to oppose the motion of the pencil, and therefore rendered it too large during expansion and exhaust, and too small during compression and admission, and thus the general effect was to increase the size of the diagram. This

Digitized by Google

friction consisted of that of the pencil on the paper ; and that of the mechanism, caused by sustaining the pressure of the pencil. The effect of the friction of the pencil was greatly reduced by the motion of the paper. The magnitude of these effects taken together on the area of the diagram depended on the construction of the instrument and on pencil-pressure. From numerous experiments it would appear possible to make a difference of as much as 5 per cent. in a locomotive in mid-gear by pencil-friction.

The conclusions, as regarded the motion of the pencil, were that the general effect of inertia and friction were both to increase the size of the diagram ; that so long as the speeds were such that the number of vibrations of the pencil during a revolution of the engine was not greater than 15, the effect of inertia was less than 1 per cent., but that if the number was greater than 30, oscillations would show themselves unless the pencil-friction was increased. They might by this be kept down till the number of vibrations was equal to 15, but not farther, and then the necessary friction would affect the area of the diagram about 5 per cent. For the diagrams to be sensibly accurate and free from oscillation the speeds must not be greater than would make the number of vibrations equal to 30. These speeds were given in the paper for Richards' indicators.

The effect of the inertia of the drum with an elastic cord was shown to be a nearly uniform elongation of the diagram. The result of the varying stiffness of the drum spring was a nearly uniform contraction. With Richards' indicator these two latter disturbances neutralised each other at a speed of 150 revolutions per minute. At other speeds the effects were apparent in the length of the diagram ; but except when the expansion was great and the connecting rod short, they did not affect the indicated pressure. The friction of the drum with an elastic cord caused the cord to be longer during the forward stroke than during the backward stroke, so that the diagram was distorted and shortened, the drum being uniformly behind its proper position during the forward stroke, and before its position during the backward stroke. This distortion diminished the area of the diagram according to the rate of expansion and the length and elasticity of the cord used. This was definitely expressed by a formula. This disturbance, the influence of which was very great in cases of high expansion, large engines, and ordinary cords, appeared to have been unnoticed. The circumstances on which it depended were the elasticity of the cord and the friction of the drum, and the question was how far these existed in the ordinary indicators. It might be said that the diagrams which led to the discovery of this effect were taken with an indicator which had been in constant use for several years. It was in apparently perfect condition, and the diagrams did not differ essentially from those which had been previously taken. The cord was one which had been supplied by the maker. The manner of the discovery was described :—For years the author had pursued in the class the method of testing the vibrations of the indicator pencil by projecting them on the crank-circle, and he had noticed that the first oscillation fell short, and shorter in the back diagram than in the front. The cause of this was not obvious, and it was partly with a view to determine this cause that Mr. Brightmore's investigation was commenced. A slight error in the reducing rod, which had a fixed centre and a slot in which a stud in the slide block worked, was altered. This, however, did not get rid of the effect. A new cord was substituted for the old one, and the effect was found to be much enhanced, the new cord being more elastic than the old one. This reduced it to the stretching of the cord, but it was only after carefully working out the effect of the inertia of the drum, and it was seen this was to lengthen the first oscillation at the back end that the friction was examined. The indicator was taken to pieces, cleaned and oiled ; then the effect was much reduced. Several new wires and cords were used, and eventually steel wire was adopted as the best. The test supplied by the oscillations could only be applied to diagrams taken at high speeds, and the test furnished by the influence upon area was vague. What was wanted was an independent means of determining the simultaneous positions of the drum and the engine piston. As the best method of meeting this, it was decided to arrange an electric circuit through the pencil to the drum, with sufficient electromotive force to prick the paper, making the engine piston close this circuit at eleven definite equidistant points in the motion backwards and forwards. This was successfully carried out, and the stretching of the cord during the backward and forward strokes was definitely ascertained. Taking the smallest results obtained with a cord, it appeared from these experiments that the least difference of stretching was to make this difference in inches 5 per cent. of the length of the cord in feet. Examples of this effect in diminishing the mean indicated pressure were given. Thus, in a locomotive cutting off at one quarter it was 8 per cent. ; in a condensing engine having 3·5ft. stroke, cutting off at one-tenth, 20 per cent. ; and the same compounded, 10 per cent.

These would seem to be the smallest results that could have occurred in ordinary practice. The conclusion, however, that hitherto the normal indicated power from engines had been from 10 to 20 per cent. too small must wait for verification. Yet there were not wanting independent evidences of such an effect. In diagrams taken from engines at high speeds the admission line would not but for this effect be vertical. It would show a certain amount of detail, and the first oscillation would not have a sharp top. Moreover, it was commonly found that the expansion line, allowing for clearance, was above the true expansion line for the steam. This apparent rise in the curve of expansion was exactly what would result if the apparent cut-off was too early, and this was the result of the effect that had been considered. The author has tried several diagrams, and found that after correction the expansion line came out very close to the true curve.

In making these comparisons the explanation of another feature of diagrams became apparent. When the two diagrams were traced on the same card there was sometimes a want of symmetry about them, and in this case the cut-off was shorter on the back than on the front diagram. This the author attributed to the friction of the drum when the cord for the back diagram was longer than that for the front. When this was the case the relative lengths of the cord were about 1 to 1·8. These observations were illustrated in a diagram from Richards' indicator. To test this diagram a tracing was taken, and reversed so that the front diagram was superimposed on the back. It was observed that the diagrams were of different lengths, and the difference was about the same as the difference in cut-off ; that notwithstanding the apparent cut-off in the back diagram was to that in the front in the ratio of 2 to 3, the expansion line of the back diagram was the same shape as that in the front ; and that if the diagrams were restored, supposing the lengths of the cords used to have been 5ft. and 9ft., the diagrams became exactly similar, and, allowing 2 per cent. clearance, the expansion line came to be the true expansion line for that cut-off. The mean pressure was 14 per cent. larger than from the original diagram.

Such instances as these seemed to sufficiently establish a case against the blind faith which appeared to be at present placed in the accuracy of the indicator diagrams. But in conclusion, the author stated that he should be very disappointed if anything in this investigation should have the effect of diminishing reliance on the indicator itself. He would have the instrument treated fairly, and instead of being the object of unthinking worship he would have it the object of careful study and experimental investigation, so that the limits of its wonderful perfection might be known exactly, and that reliance placed on it which sprang from knowledge.

BUSINESS NOTICE.—We are requested to announce that the Bernstein Electric Lamp Company have removed their offices to and have commenced manufacturing at 9A, Commercial-road, Pimlico, S.W.

NOTES.

NEW LARYNGOSCOPE.—A new electric laryngoscope has recently been invented by M. Curt W. Meyer, of New York.

THE ELECTRIC LIGHT IN MILAN.—According to *Il Giorno*, electric lighting experiments are about to be carried out in the Piazzo de Duomo, Milan.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 5th inst. amounted to £3,009.

THE EASTERN TELEGRAPH COMPANY'S CABLES.—Both the cables between Aden and Bombay are interrupted, but advices of repair are, however, hourly expected.

THE WESTERN UNION TELEGRAPH COMPANY.—A Reuter's telegram from New York states that this company has declared a dividend of 1½ per cent. for the past quarter.

CABLES IN NEW YORK HARBOUR.—On May 24 the fifth armoured cable of the Baltimore and Ohio Telegraph Company was laid across the Narrows, New York Harbour.

THE TELEGRAPH IN SIAM.—Four operators have contracted to go to Siam to introduce the Morse system of telegraphy in that country. They left San Francisco on the 1st inst.

ELECTRIC LAUNCH.—A successful trial of a new electric launch has recently been made upon Lake Maggiore, at Meina, by the Societá Industriale Franco-Italiana, of Milan.

SECONDARY BATTERIES.—We have received an excellent little treatise, being a selected paper from the *Proceedings* of the Institution of Civil Engineers upon the subject of Secondary Batteries, by Mr. Frank Geere Howard.

THE GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company are as follow:—Receipts for May, £28,800; 1st January to 31st May, £118,000; corresponding months, 1884, £106,560; 1883, £100,360.

THE TELEPHONE IN PARIS.—Considerable agitation is going on in Paris for a reduction of the telephone tariff. A league of 88 subscribers has been formed at No. 9, Rue des Vosges, and by all accounts the object is not unlikely to be attained.

THE ELECTRIC LIGHT IN BROOKLYN, U.S.A.—The opening day of the Williamsburgh Athletic Club, Brooklyn, was marked by the attendance of 7,000 persons at the games, which were continued through the evening with the aid of the electric light.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 5th inst., were £2,402, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CITY AND GUILDS OF LONDON INSTITUTE.—The summer course of lectures and laboratory instruction will commence in the institute's new buildings, in Exhibition-road, on Monday, 22nd June. Full particulars will be found in our advertisement columns.

THE SUBMARINE CABLES BILL.—The minutes of the House of Lords record that, among others, this Bill has been "read and discharged." This, however, does not mean that the Bill has been abandoned, but merely that no day has been fixed for taking the stage at which it stands.

CHAIR OF EXPERIMENTAL PHYSICS.—Particulars will be found in our advertisement columns of an invitation issued by the Council of the University College, Bristol, for applications for the Chair of Experimental Physics in that College, and also for the post of Demonstrator.

GILDING REFINED GOLD.—At a dance given last week in the Cromwell-road the hostess's daughter wore a pink rose in a spray lighted by a small lamp inside, the current being supplied by a Woodhouse and Rawson small portable accumulator carried in the dress. The effect was very charming.

CRYSTAL PALACE PARK ILLUMINATIONS.—A new feature in the illumination of the grounds is the employment of many large arc lamps, which shed electric light on the walks and terraces from elevations carefully studied to avoid interference with the effect of the multitude of smaller lights near the ground.

COMPLETION OF A NEW CABLE.—The Faraday, cable-laying steamship, arrived off Penzance on Wednesday evening. She has been engaged in the work of laying a new cable between Waterville and Weston-super-Mare. The final splice making the communication complete was effected on Wednesday morning.

THE ENGINEERS' CAMP NEAR ST. PETERSBURG.—A telegram from St. Petersburg announces that at the Engineers' Camp near St. Petersburg, detachments of infantry and cavalry will this summer be instructed in the work of the sappers and miners, including the construction and destruction of telegraphs and railways.

THE EXPLOSION ON THE "INFLEXIBLE."—The Admiralty have already provided against such accidents as that which has recently occurred by deciding to adopt the electric light even in the coal bunkers. Some of the fittings now being supplied by Messrs. Goolden and Trotter are strong hand lamps specially designed for use in the bunkers.

THE ELECTRIC LIGHT AT MORLEY.—Messrs. Hudson, Sykes, and Bousfield, woollen manufacturers, Springfield Mills, Morley, have introduced about 400 incandescent lamps into their weaving sheds. A trial which was recently made of the experiment proved very successful, and the electric light for the purposes of illuminating large rooms was demonstrated in a most striking manner.

THE TELEGRAPH TO MERV.—A Reuter's telegram dated Simla, 6th June, says:—"The Russian telegraph line has been completed to Merv, and will be further extended to Mahna, seventy miles from Sarakhs." Mahna is in all probability the Mehna of the maps, and if this is the case it would seem that the line has been extended to Merv across the Tjend, and will branch off at Mehna to Sarakhs.

THE SS. "DACIA."—The ss. "Dacia," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company, arrived in the Thames on the 7th inst., after having completed the repair of the old Havanna-Key West cable. About forty knots of new cable have been introduced to replace the same amount, which was picked up and stored on shore for future use in repairs should necessity arise.

DOMESTIC LIGHTING.—Messrs. Verity and Sons, of Covent-garden, have recently put down an installation of over 230 lamps for Chas. Combe, Esq., at Cobham Park, Surrey. The experiments have so far resulted in a most pronounced success. The same firm are at present lighting up Errol Park, Scotland, for Ogilvie Dalgleish, Esq., with 170 lights, and have obtained the contract for a similar installation in the south of England. We wish them every success.

TEMPORARY LIGHTING.—At a dinner party given at 69, Portland-place on the 2nd inst. the rooms were lit by incandescent lamps. The work was carried out for Messrs. W. Hucks and Co. by the Electrical Power Storage Company. At a ball given after a wedding at St. Ronan's, Tulse Hill, S.W., on the 11th inst., the rooms and conservatories were lit through-

Digitized by Google

out by incandescent lamps. The work was carried out by the Electrical Power Storage Company.

THE DEFENCE OF PORT CHALMERS.—Mr. W. Prince, electrician to the Union Steamship Co. and also to R. E. Fletcher and Co., of Dunedin, has been appointed by the Defence Minister to take charge of the proposed submarine torpedo arrangements at Port Chalmers. Mr. Prince brought with him from Wellington instructions for carrying out the scheme, and he will be furnished with the necessary assistance in the shape of men and material by the Public Works Department.

THE NEW ZEALAND TELEGRAPHS.—The Wellington quarterly return shows that the telegraphic revenue for the past quarter was as follows :—

Messages.	Number.	Value.
Total for the Colony	401,412	...£26,776
Corresponding quarter 1884...	362,405	... 23,407
Government telegrams	62,051	... £6,606
Corresponding quarter 1884...	58,036	... 5,543

THE UNITED TELEPHONE COMPANY.—The directors of this company, at their meeting held on the 10th inst., decided, subject to audit and after making provision for depreciation, &c., to recommend at the forthcoming general meeting a dividend for the half year ended 30th April last at the rate of 7s. 6d. per fully-paid share, part-paid shares receiving in proportion, making, with the interim dividend on 2nd December last, a total distribution for the twelve months ended 30th April last of 10 per cent. per annum, carrying forward a substantial sum to reserve.

ELECTRIC LIGHT FOR INTERNAL NAVIGATION.—At the International Congress of Internal Navigation, held last week at Brussels, M. de Saint-Hubert, in describing his project for a uniform system of water ways connecting the principal cities of Europe, referred to the use that might be made of the fall of water over the weirs in canalised rivers for driving turbines connected directly with dynamo machines. The current thus generated would serve to maintain arc lights for illuminating, not only the locks and their approaches, but also the shores, so that navigation might be continued by night as well as by day.

THE ROYAL SOCIETY.—On Wednesday evening a *conversazione* given by the Royal Society took place at Burlington House. Among those present were Prince Bonaparte, Lord Bramwell, Sir J. Lubbock, M.P., Sir F. Bramwell, Sir James Paget, Sir A. Hobhouse, Prof. Ray Lankester, and many other gentlemen distinguished in science and art. The guests were received by Prof. Huxley, the president of the society, and many objects, scientific and mechanical, were displayed, including a number of Edison incandescent lamps, exhibiting molecular shadows and transparent deposit of copper, and other kinds of electrical apparatus.

THE HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY.—A petition for winding up this company has been presented to the High Court of Justice by Mr. Robert Hammond, who is described as a "merchant, a creditor, and contributory" of the company. The petition is directed to be heard by Mr. Justice Kay, on the 20th inst. Provision will probably be made for carrying out contracts that have been entered into by the company to light, among other places, the Mansion House, the Grand Theatre at Islington, the Brighton Aquarium, and the Prince of Wales Theatre, Birmingham, and an order has been made authorising the liquidator to pay wages not exceeding £200 a week, subject to proper security being provided.

PROJECTED ELECTRIC LIGHTING OF A TOWN IN NORWAY.—We understand that the town of Bergen in Norway is to be lighted by electricity. A company is being formed to start a central station, and already promises have been received to take 3,000 incandescent lights and 70 arc lamps. The price of gas is 6s. 6d. per 1,000, and the price of coal from 11s. to 12s. per ton delivered at the central station. The engineer, Mr. J. S. Hopstock, is now in London for the purpose of getting tenders from the leading English firms, and it is hoped that the installation will be at work before Christmas this year. The company expects to pay from 5 to 6 per cent. to the shareholders, and obtain the sole concession of the town council for a number of years.

THE SIXPENNY TELEGRAMS BILL.—Nothing is certainly known yet as to the fate of this Bill, although there were confident statements yesterday that it would be abandoned—at all events in its present form. This conjecture is based simply on the fact that Lord John Manners, the past and probably future Conservative Postmaster-general, disapproves of the abolition of free addresses. If a Conservative Ministry come into office it will be difficult, therefore, for them to press the Bill forward in its present shape. On the other hand, all the departmental arrangements and calculations are based on the halfpenny a word rate all round, including the addresses; and it will be next to impossible to reconstruct the Bill at the last moment on a different basis. But the Conservatives have not yet taken office; and nothing can be safely predicted as to the Bill until they do.

NEW ELECTRIC RAILWAY.—According to an American contemporary, a new electric railway, the invention of Professor Short, of the Denver University, has recently been given a practical test. The inventor claims for this invention that it possesses principles not used in the Edison and similar inventions. The test was made over 300 feet of track built in a semi-circle and having at one point a grade of 250ft. to the mile. The track was a few inches narrower than that of a narrow-gauge railway. The dummy car built for the occasion contained five persons, and was propelled over the track at a lively rate of speed. Some time ago a company was formed to build a cable-car line in Denver, on which this invention is to be used, and already tracks are laid upon a number of the streets.

THE NAVAL AND MILITARY CLUB INSTALLATION.—We are informed that the contract for this installation has been obtained by Messrs. B. Verity and Sons, of King-street, Covent Garden. The plant is to consist of two double cylinder engines and boilers, two Edison dynamos of the latest form, and a large set of fifty-five Elwell and Parker accumulators. The engine room will be specially constructed at the back of the club, and throughout the whole installation every attention will be paid, and no expense spared to make this one of the most successful examples of electric lighting. This club will, no doubt, add to its already great and deserved popularity by being the first in London to enlist so necessary an adjunct to comfort in its service. We may mention that there were five tenders sent in for this work. The plant is to be completed and in operation by the end of August.

HEARING THE EARTH'S MAGNETIC INDUCTION.—Dr. Schaper recently demonstrated to an audience the magnetic induction exercised by the earth. A number of telephones were arranged in series upon one circuit, which was rapidly made and broken by an interrupter. A telephone was then repeatedly turned end for end in such a way that its north and south poles were alternately the uppermost, and at each reversal a crack was heard in all the telephones, resulting from the induction of the

Digitized by Google

earth on the central magnet. If the experiment be made with an induction bobbin only the crack is extremely feeble, due in that case to the induction of the earth on the bobbin. The telephone may be replaced by a magnet wrapped with insulated wire. The degree of sensibility of the telephones can be determined if the axis of rotation of the magnet employed in the experiment be brought little by little nearer to that of the inclining apparatus.—*Scientific American.*

CAUSE OF EARTHQUAKES.—Our contemporary, the *St. James's Gazette*, says that M. Perey, a Dijon astronomer, offers a novel explanation of the frequency of the earthquakes which have produced so much disturbance on the surface of our planet of late. His theory is that they are caused, like the tides, by the attraction of the sun and moon; and he argues that it is only natural to suppose that the sea of fire in the interior of the globe obeys the same influences as the ocean on its surface. M. Perey has investigated the particulars of no fewer than 5,400 different shocks of earthquake; and a comparison of their dates demonstrates that these phenomena are most frequent during the periods of full and new moon. He has further ascertained that the shocks have been most violent when the moon has been in the meridian of the place where they occurred, just as the tide in a seaport over whose meridian the moon is passing is higher than that in any of the neighbouring ports.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—The general meeting of the American Institute of Electrical Engineers was held on 20th May, at the house of the American Society of Civil Engineers, at 127, East Twenty-third-street. The first paper was on "The Protection of Inventions," by Mr. Frankland Jannus, of Washington. In the course of the discussion which followed it was stated that there was no chemical or electrical laboratory in the Patent Office. A resolution to the effect that a committee be appointed to call the attention of Congress to the needs of the Patent Office, especially in regard to the class of electricity, was referred to the council for action. A paper on "The Cost of Mine Lighting," by Mr. F. P. Mills, was read by the secretary. Mr. Edward P. Thompson read a paper on "The Electric Arc Lamp Frictional Clutch," and described at length a clutch in the shape of a spiral spring, the use of which he claimed would produce good results in the way of steadiness of light and regularity of feeding the carbon.

THE EARTHQUAKE IN CASHMERE.—Further particulars are given of the severe earthquake which occurred recently in Cashmere. The barracks at Serinagur were destroyed, about 100 men and 150 horses being buried in the ruins. Forty-six men were killed, and 50 were seriously hurt. Forty-one lives were lost in the city, and many persons were injured. The Maharajah's palace was partly destroyed, and the British residency was greatly damaged. Many villages were wrecked, and much damage was done throughout the valley. A mosque at Sopar fell, burying 200 persons. No Europeans are reported to have been killed. It is stated that the shocks continued all the next day. A Reuter's telegram from Simla, 6th June, announces that the British Resident in Cashmere reports that shocks of earthquake continue to be felt in that province. In several places the earth opened and swallowed up houses, while hot water and clouds of sulphurous dust were ejected from the chasms. These phenomena were accompanied by loud subterranean rumbling. Generally speaking the movement of the earth has been comparatively slight.

OVERHEAD WIRES.—According to the *Pall Mall Gazette* the United Telephone Company have determined not to proceed with their Bill dealing with the erection of overhead wires. The Bill provided that the company might erect and maintain wires over any land or road, provided that by so doing they should not be deemed to acquire any right other than that of user only in the soil. Provision was made that the company should do as little damage as possible, and should make full compensation (the amount to be determined in case of dispute by the Local Government Board) for any damage caused by the exercise of their powers. The powers of the company were to be subject to the restriction that they should not erect posts upon or lay wires under any property without the consent of the occupier; and special restrictions were imposed with regard to interference with public roads. The Press Association learns that the Government do not intend to follow up the recent report of the Select Committee on Overhead Wires by any legislation, considering that the recommendations passed by the majority of the committee were impracticable, and would invade private rights to an extent for which the Government cannot make themselves responsible.

HONOURS FOR TELEGRAPHISTS.—In connection with the festivities incident upon the celebration of Her Majesty's birthday, the honour of knighthood has been conferred upon Mr. Henry C. Mance, the inventor of the heliograph and of several methods of electrical testing which will doubtless be well known to many of our readers. Mr. F. E. Baines, one of the assistant secretaries of the General Post Office and Inspector-General of Mails, has, in recognition of his many valuable services in connection with his department, received the well-merited distinction of the Civil Companionship of the Bath. Mr. Baines was for many years in the service of the Electric and International Telegraph Company; during that time he formulated a scheme for the transference of the telegraphs to the Government, which, we have every reason to believe, led to the adoption of the present system. He was then, or shortly after the transfer took place, appointed to the post of Surveyor-General of Telegraphs, a position in which he remained until the project of establishing an efficient parcels post engaged his attention. Mr. Baines ultimately received the appointment of Assistant-Secretary to the Post Office and Inspector-General of Mails, in order that he might be better able to devote himself more particularly to the departmental arrangements and alterations which that scheme entailed.

EDISON'S LATEST INVENTION.—Mr. Edison's latest invention, an arrangement to telegraph from moving trains, is thus described by a recent visitor to his laboratory:—Overhead was a board eight inches wide, suspended from the ceiling by ropes fastened to one of its edges. One side of it was covered with tin foil and was facing toward a wall twenty feet distant. "That," said Mr. Edison, "is my railroad signal; I make electricity jump 35ft., and carry a message. This is something quite new, no induction has ever been known that extended over three or four or five feet. This invention uses what is called static electricity, and it makes every running train of cars a telegraph station, accessible to every other telegraph station on the road. Messages may be sent to and from conductors, and to and from passengers. It requires no extra wire, either under the cars or at the side of the cars, but uses the ordinary telegraph just as it is put up at the side of the track. This white board is a receiver and transmitter. A board like it is to be fastened lengthwise along the peak of each car, where it will be out of the way and will not be a blemish. When the train is telegraphed to, the message jumps from the wire on the side of the track and alights on this board, and is conveyed to the battery in the train below. It works beautifully from those wires strung yonder. I was as much astonished as anybody

Digitized by Google

at finding out what could be done. It costs very little, moreover, as 300 miles of road can be equipped for 1,000 dols."

ELECTRIC HIGH AND LOW WATER DETECTOR.—A description of a new electric high and low water detector appeared in a recent issue of the *Scientific American*. The apparatus is substantially as follows:—"A galvanised iron stand pipe, about five inches in diameter, and of suitable length, is connected with the boiler by two pipes. Within the pipe is a float having a stem a little longer than the range between high and low water. The stem passes through a guide, and has a copper disc near the float, to signal high water, and another near its upper end, to make the connection for low water. The hole in the guide is bevelled to prevent the binding of the stem when the float shifts from side to side. The discs may be placed at any point on the stem. The electric circuit is completed through binding posts, which are connected with wires leading to an annunciator. The inner end of each post carries a copper plate, with which the discs come in contact as the float approaches either the high or low water level, and in order to insure proper electrical contact each plate is slitted into separate fingers in the bearing parts; the yielding of the fingers affords more certainty of connection with both plates, in case the float should happen to incline a little more to one side than the other. The discs are placed a considerable distance above the water, where they will not be liable to be fouled with deposits. When several boilers are provided with the detector a multiplex annunciator is used, so that each boiler may be represented by a special signal. The binding posts are insulated from the stand pipe by means of a rubber tube and washers, fitted through the holes of the pipe, and against the sides between a collar and a nut. This apparatus is now in successful operation at the nail works of the Ellis and Lessig Steel and Iron Company, of Pottstown, Pa. When the alarm is sounded the annunciator not only shows which boiler is in trouble, but also indicates whether it is high or low water."

LIGHTING OF A MINE IN NEW ZEALAND.—The Kaitangata Railway and Coal Company's mine has recently been lighted by electricity. Our contemporary the Otago *Daily Times* says:—"If the experiment is satisfactory, the mine manager states that the light will be permanently adopted for working the mine. The contrast between the ordinary flare or oil lamps used by the miners and the electric lamps was very striking. The fumes are smoky and dirty, and to unaccustomed eyes seemed only to make the surrounding darkness more intense; on the other hand, the electric lamps shone out bright and clear, penetrating the gloom and enabling the visitors to see all that was to be seen. The electrical apparatus was lent for the occasion by Messrs. R. E. Fletcher and Co., electrical engineers and contractors, of Dunedin. The installation was necessarily of a temporary character, having been all erected in a couple of days. Samples of the various fittings used where the light is installed as a permanency were shown in working order at the entrance of the tunnel, so that visitors who did not care to venture into the workings were able to examine and have the working of the apparatus explained to them. Although the Kaitangata mine is one of the first in this colony to use the electric light underground, electrically lighted mines are by no means such a novelty as many people would suppose. In the various Australian Colonies, notably Victoria and Queensland, there are no less than 15 gold and one coal mining companies which have adopted this new system of lighting both their surface and underground works. In some of these mines the light has been in successful use for nearly three years. When it is remembered that an ordinary candle vitiates as much air as two human beings would, and that these small electric lamps, being hermetically sealed in a glass bulb, can neither consume any oxygen nor vitiate the air in any manner, this fact alone speaks volumes in favour of the use of the electric light in places such as these, where the problem of efficient ventilation is always a difficult one to solve, to say nothing of the fact that neither wind nor water extinguishes it."

AN ALARM CANDLE BALANCE FOR PHOTOMETERS.—An ingenious automatic method for signifying the rate of consumption of candles used in photometrical work has, says the *Journal of Gas Lighting*, been devised by Dr. Hugo Krüss, of Hamburg, for the gas examiners of St. Petersburg, and has been recently described and illustrated in the *Journal für Gasbeleuchtung*. The arrangement is very simple. The candle-holder is hung in an unequal arm balance, as in the Sugg-Letheby photometer, in the position required for making an observation. The beam of the balance has a long pointer hanging down from the fulcrum, which marks the position of the balance on a vernier scale at the foot of the pillar. There are, as usual, two metallic pins at the two opposite ends of this scale, and in the middle a movable pin which is in electrical connection with a battery and a bell. Directly the pointer comes into contact with this pin the circuit is completed and the bell rings. The method of using the balance is readily understood. The candles being lighted and fixed in position are weighed until the pointer just swings clear of one stud of the vernier, when any desired weight may be placed in the pan provided for the purpose underneath the candles, the clock being started at the same moment. Observations may then be taken while the candle burns; and the instant the weight placed in the pan is lifted by the consumption of the candles and the weight in the opposite pan, the pointer swings back and touches the pin, which completes the circuit and so rings the bell. This, of course, indicates, in conjunction with a glance at the clock, the precise rate of consumption of the candles, without touching or in any way interfering with them. The arrangement is a very neat one, the battery, electro-magnet, and bell being mounted on the balance stand, and all contacts being so placed as to be readily removed out of the way when not required. For this a special form of cell is used, with an arrangement for preventing waste when not required for the purpose specified.

THE ELECTRIC LIGHT AT BOCKING PLACE.—An Essex contemporary says:—"The instances of the introduction of the electric light into private houses are at present so few, that we were pleased to have the opportunity of inspecting the results of the laying on of the light at the residence of Mr. S. Courtauld, of Bocking Place, which has just been carried out by the Consolidated Electric Company, of 68A, Cow Cross-street, E.C. The experiment appears to be an entire success, the house being brilliantly and effectively lighted by 64 Swan incandescent lamps, which are entirely under control by means of 'switches' conveniently arranged; and the ease and simplicity with which these are worked, and by means of which the lamps are instantaneously lighted, and as instantaneously extinguished, is remarkable. In the drawing room there are eight 16-candle lamps, which are so arranged that they can all, or any number of them, be lighted at once. In this room are two new developments of electric lighting—one a reading lamp, which can be moved about on the table as may be desired, or can be instantly disconnected and taken away, the circuit being completed by pressing into two small invisible holes in the table the ends of two wires attached to a small button. The table can also be moved to any part of the room; there is likewise a movable hanging lamp over the piano, which can be raised or lowered at will. The lighting of the billiard room

Digitized by Google

is very successful, there being no shadow upon the table. Mr. Courtauld has had the light, or the wires, carried all over the house—from the cellars to the bed rooms, including kitchens and offices—and one of the most striking features in the system adopted is the use of accumulators, or receptacles for the electricity, which is stored much after the fashion of gas in a gasometer, the result being that by working the engine a few hours every day sufficient electricity is generated and stored to last many hours. The lamps vary from 10 to 50 candle-power each. There is no danger from fire, as if any of the wires should by accident become heated a small magnet is brought into play, which instantly and automatically disconnects the whole system from the accumulators. The motive power is a three and a-half horse Otto gas engine, *and the gas consumed, we are informed, actually produces more light in electricity than it would if burnt in the usual manner.* The whole cost of the installation, including enginehouse, engine, dynamo, accumulators, wire, electroliers, brackets, lamps, and labour was, we believe, under £500. Of course a long period of working is the only real test of actual success, but there appears in this case every probability that this has been obtained."

PRODUCTS OF THE ELECTROLYSIS OF DILUTE SULPHURIC ACID.—Mr. F. Richarz has recently treated this question. The experiments of Faraday, Schönbein, and others have demonstrated that by the electrolysis of dilute sulphuric acid there are formed, besides electrolytic gas, hydrogen peroxide, and ozone, to which Berthelot has recently added persulphuric anhydride, S_2O_7. In this paper experiments are detailed, tracing the connection between the proportion of ozone, hydrogen peroxide, and persulphuric anhydride formed, and the conditions of the experiment. The observation of Schönbein, that for the formation of a considerable quantity of hydrogen peroxide a considerable electric intensity is required at the positive electrode, and a low temperature, was at first confirmed. But in the course of the research it was noticed that the mutual reduction of the hydrogen peroxide and the persulphuric anhydride at the negative pole (a probable assumption of Hoffmann and Berthelot) causes a quantity of hydrogen, corresponding with a certain quantity of oxidising or available oxygen, to disappear, and thus cause a deficit in the products of electrolysis. Thus the sum of the evolved electrolytic gas, of the oxygen evolved as ozone, and of the oxidising or available oxygen in the persulphuric anhydride, is always less than the volume of electrolytic gas, as calculated from the observed deviation of the tangent galvanometer. Mr. F. Richarz considers that this deficit is caused partly by the reduction of the persulphuric anhydride, and partly by the absorption of the electrolytic gas by the dilute sulphuric acid. By increasing the temperature this deficit decreases, owing, firstly to the decrease of persulphuric anhydride formed, and secondly to the diminution of solubility of the electrolytic gas. It is remarked incidentally that the proportion of persulphuric anhydride formed decreases with rise of temperature more rapidly than that of the ozone. The influence of the duration and intensity of the current and also of the concentration of the acid on the relative proportions of the products of electrolysis is also discussed. It is shown that the proportion of persulphuric anhydride, ozone, and the deficit observed increases with the time of passage of the current, whereas an increase of intensity of current produces precisely the reverse result; this is in accordance with Wiedermann's observations. As regards the effect of concentration, the results given in tables show that with an acid containing 10-20 per cent. H_2SO_4 the proportion of oxygen as ozone and persulphuric anhydride, as also the deficit, is small, and no hydrogen peroxide is formed; with an acid containing 20-40 per cent., the proportion of oxygen as persulphuric anhydride and the deficit increases; with acids containing 40-90 per cent., the proportion of oxygen as ozone and persulphuric anhydride and the deficit decreases, whilst the proportion of hydrogen peroxide *pari passu* increases. The author proposes to examine the important question of the effect of the electromotive force of polarisation on the formation of these peroxides.

BRAUER'S DYNAMOMETRIC BRAKE.—According to the *Proceedings* of the Institution of Civil Engineers, two striking characteristics distinguish this brake, the invention of Mr. Brauer, from others of the same class. Firstly, it does not require when in action that its frictional surfaces should be constantly wetted; with ordinary wooden brakes this is absolutely necessary. Secondly, once the clutching action is established the brake regulates itself automatically, and further, there is not required, as with the ordinary brake, a long and cumbersome lever. An analogous arrangement to that of Mr. Brauer has been suggested by Mr. Kratz in his essay upon the dynamometric brake. In the Brauer apparatus, instead of wooden jaws hugging the rims of the pulley, an iron band is used for flat rim pulleys, and wire ropes for grooved pulleys. The apparatus is composed of the following assemblage of parts:—1st. The iron band or wire rope. 2nd. The clutch-producing arrangement and the regulation of the tension of the clutch-producing bands or ropes. The clutch or pressure of the bands or ropes upon the surface of the rim of the pulleys produces a friction corresponding to the effective work of the motor. The moment of this friction multiplied by 2π gives the work produced per revolution. To calculate this it only needs to determine an equal moment given by the additional charge or weight p, augmented by the weight of the regulating organs, the two weights affixed to the axis of the pulley, and p the moment required to maintain the system in equilibrium. The iron band applied to an ordinary flat rim pulley is provided with four double guides to retain the band in position, which is fixed up from the underside by means of a stirrup bolt and link and a safety cord, in such a way as to allow the band to have a play of 100 millimetres. These safety measures can be modified according to local circumstances, and when the under part of the pulley or drum is inaccessible. The following is a summary of the observations made by Mr. Burghardt, who has carefully tested Brauer's dynamometric brakes:—Needle lubricators do not sufficiently lubricate the apparatus; tallow is preferable as the lubricating medium. The brake worked well during the time the temperature of the pulley-rim did not exceed 35° to 40° centigrade, and even up to 80° centigrade the action was still satisfactory, but the lubricating medium became too fluid, and was thrown off the grooves by the centrifugal force due to the speed of the pulley. The Brauer brake worked well for two hours with a load corresponding to 25 horse-power. Summary of the advantages and disadvantages of the Brauer brake over those of the ordinary description:—1. The necessity of continually cooling the pulley-rim by subjecting it to a stream of water, which is a great drawback to the use of ordinary brakes, is in the Brauer brake avoided. 2. The brake is not so cumbersome, and can be applied to motors *in situ* and in confined spaces. 3. The oscillations are very limited, and consequently the observations are more exact than with the ordinary brake, and the diagrams obtained by the indicator are clean and clear, and easy to calculate. On the other hand, the Brauer brake is relatively rather more costly than those of the ordinary class, and it requires in its application a little more care than those of the ordinary and unscientific class.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 7.)

Impressed Electric Force in Dielectrics.

A comparison is often made between distributions of magnetic induction and of electric current. There is, however, a far more satisfactory analogy between magnetic induction and electric displacement in a dielectric, which may be pushed much further before correspondence ceases. So far as mere distributions in space go, of the three phenomena of conduction current, electric displacement in a dielectric, and magnetic induction, we may conveniently compare them simultaneously.

First let there be a distribution of impressed electric force e_1, in a conductor of conductivity k (infinitely extended in the general case, with the conductivity different at different places), setting up a steady state of electric force E_1, and conduction current C. We have the three conditions

$$C = kE_1, \qquad \text{div. } C = 0, \qquad \text{curl } (e_1 - E_1) = 0. \quad . \quad (80a)$$

Secondly, in a non-conducting unelectrified dielectric of capacity c, in which a distribution of impressed electric force e_2, sets up a steady state of electric force E_2, and displacement D, we have

$$D = cE_2/4\pi, \qquad \text{div. } D = 0, \qquad \text{curl } (e_2 - E_2) = 0 \quad . \quad (80b)$$

Thirdly, in a medium of permeability μ, in which a distribution of impressed magnetic force h, sets up a steady state of magnetic force H, and induction B, we have

$$B = \mu H, \qquad \text{div. } B = 0, \qquad \text{curl } (H - h) = 0. \quad . \quad (80c)$$

These three sets of conditions are exactly similar. We have in each case a "force" and a "flux." The first condition is the linear relation between the force and the flux, *i.e.*, Ohm's law, &c. The second condition is that of continuity of the flux, asserting that its divergence or convergence is zero everywhere, or that the flux is distributed entirely in closed tubes. The third is the force equation, what the equation of induction becomes when the state is steady, the third conditions in (80*a*) and (80*b*) being examples of curl $(e - E) = \mu\dot{H}$, with $\dot{H} = 0$, and that in (80*c*) arising from curl $(H - h) = 4\pi\Gamma$ with $\Gamma = 0$. The difference between the actual and the impressed force, or the natural force of the field itself, has no rotation, or its line integral round any closed line whatever is zero. Or,

$$E_1 = e_1 + F_1, \qquad E_2 = e_2 + F_2, \qquad H = h + F_3,$$

where F_1, F_2, F_3 are "polar" forces entirely, derived from single valued scalar potentials, whose space variations give the polar forces; thus $F_1 = -\nabla P_1$, $F_2 = -\nabla P_2$, $F_3 = -\nabla\Omega$, where P_1 and P_2 are electric potentials and Ω magnetic potential.

The three conditions serve to determine unambiguously the complete solution, so far as the force and the flux are concerned, when the impressed force and the distribution of conductivity, &c., are given. To the impressed force we require to add a polar force to make up a complete system of force satisfying the continuity of the flux. At the poles, or places where the polar force converges, or diverges, we may, if we like, put imaginary matter, electric or magnetic, as the case may be, repelling according to the inverse square law, and regard the potentials as the potentials of the matter. Each distribution of impressed force requires a particular polar force to supplement it; except when the impressed force is so distributed that it can by itself satisfy the continuity of the flux, and the linear relation between the flux and the force. Thus, when div.$ke_1 = 0$, or div.$ce_2 = 0$, or div.$\mu h = 0$, no polar force is needed, and there is none, or the potential does not vary. We have then $C = ke_1$, $D = ce_2/4\pi$, and $B = \mu h$ respectively. On the other hand, should the impressed force be itself polar in its distribution, there is no flux produced. We then have $e_1 = -F_1$, &c., and $E_1 = 0$, &c.

Now, if in the above three problems, the distributions of impressed force—electric or magnetic, as the case may be—are identical, and also the distributions of conductivity, &c, in space, then also the three fluxes have identical distributions. Practically, as neither the permeability nor the capacity (in non-conductors, at any rate) can vanish, we must not let the conductivity be zero anywhere in the conduction current problem; *i.e.*, all space must be conducting, more or less, to get identical distributions of current to those of induction and displacement respectively. We cannot confine either of the last to definite closed channels, as we do electric currents, by arrangement of matter, although we can do so by proper distributions of the impressed force, viz., in the above mentioned cases of no polar force.

The distributions of Joule heat per second (or dissipativity) of electric energy (or energy of displacement), and of magnetic energy are also similar, being E_1kE_1, $E_2cE_2/8\pi$, and $H\mu H/8\pi$ respectively per unit volume, and if their totals through all space be Q, U, and T, respectively, we have

$$Q = \Sigma E_1kE_1 = \Sigma e_1kE_1 = \Sigma e_1ke_1 - \Sigma F_1kF_1 \quad . \quad (81a)$$

$$8\pi U = \Sigma E_2cE_2 = \Sigma e_2cE_2 = \Sigma e_2ce_2 - \Sigma F_2cF_2 \quad . \quad (81b)$$

$$8\pi T = \Sigma H\mu H = \Sigma h\mu H = \Sigma h\mu h - \Sigma F_3\mu F_3 \quad . \quad (81c)$$

In the first form of expression, as ΣE_1kE_1, the quantity summed is the actual amount in the unit volume. In the second form the summation extends only where there is impressed force, being of the scalar product of the impressed force and the actual flux.

In the third form, there are two summations, both necessarily of positive amounts, whose difference gives the dissipativity, &c. The first extends only where there is impressed force, being the greatest value of Q, &c. The second extends over all space where there is polar force, and vanishes when there is none. The parts depending on the polar forces may also be expressed in terms of the potential and of imaginary matter. Thus—

$$\Sigma F_1kF_1 = \Sigma P_1\rho_1, \text{ if } \rho_1 = \text{conv.}ke_1, \quad . \quad . \quad . \quad (82a)$$

$$\Sigma F_2cF_2/8\pi = \Sigma\tfrac{1}{2}P_2\rho_2, \text{ if } \rho_2 = \text{conv.}ce_2/4\pi, \quad . \quad . \quad (82b)$$

$$\Sigma F_3\mu F_3/8\pi = \Sigma\tfrac{1}{2}\Omega\sigma, \text{ if } \sigma = \text{conv.}\mu h/4\pi. \quad . \quad . \quad (82c)$$

Note here that the distribution of imaginary matter is not the same (in general) as that before mentioned, measured by the divergence of the polar force. Here the matters are distributed where the impressed force, multiplied by the conductivity, &c., has convergence. In (82*c*), σ is the density of imaginary magnetic matter on the ends of a magnet. But in (82*a*) and (82*b*), ρ_1 and ρ_2 are not distributions of electrification, for there is none in either case. The electrification is measured by the divergence of the displacement, which is zero under the stated conditions.

We may also employ vector potentials in all three cases. Thus

$$Q = \Sigma E_1C = \Sigma H_1G_1 \quad . \quad . \quad . \quad . \quad . \quad (83a)$$

$$U = \tfrac{1}{2}\Sigma E_2D = \tfrac{1}{2}\Sigma ZG_2 \quad . \quad . \quad . \quad . \quad . \quad (83b)$$

$$T = \tfrac{1}{2}\Sigma HB/4\pi = \tfrac{1}{2}\Sigma A\Gamma \quad . \quad . \quad . \quad . \quad (83c)$$

The relations of these new quantities are

$$\text{curl } H_1 = 4\pi C, \qquad \text{curl } e_1 = 4\pi G_1, \quad . \quad . \quad (84a)$$

$$\text{curl } Z = cE_2, \qquad \text{curl } e_2 = 4\pi G_2, \quad . \quad . \quad (84b)$$

$$\text{curl } A = \mu H, \qquad \text{curl} h = 4\pi\Gamma, \quad . \quad . \quad (84c)$$

In the conduction current case (83*a*) and (84*a*), H_1 is the magnetic force of the current, and G_1 is an imaginary distribution of magnetic current, viz., where the impressed force has rotation, or varies laterally. In (83*b*) and (84*b*) G_2 is also an imaginary magnetic current, similarly related to the impressed force, whilst in the magnetic case (83*c*) and (84*c*), Γ is similarly related to the impressed magnetic force, and is the well-known imaginary electric current which would (if it were a real current) correspond to the same state of magnetic induction as the impressed force h sets up. The summations do not extend over the whole region of impressed force, but to portions only, perhaps round a single line. This we will illustrate in the conduction current case. The formula $Q = \Sigma H_1G_1$ has some suggestiveness in connection with the transfer of energy, but turns out to have no very important application. As we remarked before, if the impressed force be polar, there is no flux. For there to be any flux at all, the

Digitized by Google

impressed force must have curl somewhere, and $Q = \Sigma H_1 G_1$ shows the exact dependence of the activity on the situation and amount of this curl. Take a simple voltaic circuit, copper and zinc in acid, and the copper continued by a copper wire to the zinc outside the liquid. Suppose the impressed forces are entirely confined to the metal-acid surfaces, and are of uniform strength over each metal. Then the places of summation are the two wind and water lines. One place gives the amount of energy leaving the zinc per second, the other the amount arriving at the copper, and their difference is the amount of Joule heat in the circuit. Next suppose that the zinc-air force equals the zinc-acid force, and that the copper-air force equals the copper-acid force. There is now only one place of curl of impressed force, viz., the air boundary of the copper-zinc junction, and the summation round that line only gives the value of Q. But not only may we thus shift the places of summation outside the battery, but we may locate them altogether away from the circuit if we like by suitable dispositions of impressed force outside the circuit, which will not in any way disturb the state of magnetic force and current provided we keep the same impressed forces in the battery as before, although they will alter the paths of the transfer of energy. In problems (*b*) and (*c*) there is, of course, no transfer of energy at all after the steady states, which are alone considered, have been set up.

In problems (*b*) and (*c*) we may also compare the mechanical stresses. They are such as to increase U or T respectively when allowed to act, by letting the impressed forces do more work. Two bar magnets repel with like poles, and attract with unlike poles approached, whilst either pole of either will attract soft iron and repel bismuth. Similarly, take two bars of a dielectric and put in them impressed electric force parallel to their lengths. Like ends will repel and unlike attract one another, whilst either pole will attract a piece of solid dielectric of greater capacity than air (in which all are immersed), in which there is no impressed force, or repel it if its capacity be less than that of the air, or other surrounding medium. The same will happen if there be intrinsic displacement in the solid bars, such as arises from so-called "absorption." (If in the conduction current problem there were a corresponding tendency for Q to increase, then a copper ball in mercury conveying a current would be attracted by either electrode, where the current has greater density.)

Dismissing now the problems (*a*) and (*b*), consider something quite peculiar to (*c*), that of dielectric displacement. Both the conduction current and the magnetic induction are continuous, as expressed by the second condition in each case. We have also written down the same condition for the electric displacement. No arrangement of impressed electric force can *create* any discontinuity in the displacement, provided there be no conduction anywhere. Should there be any discontinuity, its proper measure is the divergence of the displacement. That is, ρ the volume density of the electrification—for it is nothing else than discontinuity in the displacement—is given by

$$\rho = \text{div.D}.$$

Supposing there to be any such discontinuity, it will remain a fixture, or only be varied in distribution by motion of matter carrying the electrification with it—of matter, because it appears most probable that there cannot be any electrification without the presence of matter; or, the displacement in the electro-magnetic medium itself, the ether, is always continuous. To get rid of the electrification there must be conduction. Conversely, to create electrification there must be conduction. The two statements go together.

Now the essential property of a conduction current is dissipation of energy by the heating effect produced. Destruction of electrification by disruption of the dielectric is therefore of the nature of a conduction current, at least partly, although the simple metallic conduction law is not followed, and, in fact, it is not known definitely what is the exact course of events, even when considered merely electrically. But we should never, in attempting to explain something, go from the complex and ill-understood to the comparatively simple and mathematically expressible, but pursue the other course. We may say then, with tolerable certainty, that to create electrification there must be (1) the presence of matter; (2) impressed electric force, *i.e.*, a cause in operation which tends to produce an electric current (if we like we may say which tends to produce magnetic force, and regard the current as an affection of the magnetic force), which is neither the polar electric force nor the electric force of induction, these being the only two naturally belonging to the electro-magnetic medium; (3) conduction, with dissipation of energy.

Nothing is easier than to create electrification experimentally or involuntarily by the contact or friction of bodies. Imaginative explanations may be readily made up, and are likely to be of very little value. It is, then, necessary to be somewhat general, or vague, in order to keep on the straight and narrow path. We may create electrification by the contact of different conductors, either by means of the small known contact force of thermal origin, or of the much larger air-surface contact forces of chemical origin, and, so far, it is easy to recognise the presence of the matter, of the impressed force, and of the conduction. Similarly, by the contact of a conductor and a dielectric, if there be similar impressed forces present. No friction is absolutely necessary. But if we set two dielectrics in contact, without any connection with conducting matter, no impressed electric forces can, without a change of conditions, set up any electrification. Some friction is needed, and with it there is conduction, or equivalently disruption. The actual original impressed electric forces need not be great, and are probably small. It is the act of separating mechanically the opposite electrifications produced by the friction, at first extremely close together, that is the main cause of the high difference of potential observed after separation, together with the similar separation taking place during the friction. The electric field is, for the most part, set up during the separation, and derives its energy in the main from the mechanical work then done.

Now, having got electrification—ρ per unit volume, say—the field due to it is settled by the three conditions,

$$\text{D} = c\text{E}/4\pi, \qquad \text{div.D} = \rho, \qquad \text{curlE} = 0 \quad . \quad . \quad . \quad (85)$$

differing from the former, equations (80*b*), in the second and third, in the absence of impressed force and the existence of ρ. The field is definitely determined by (85); the force is polar completely, and the energy is

$$\Sigma \text{E}c\text{E}/8\pi = \tfrac{1}{2}\Sigma \text{P}\rho,$$

if P be the potential.

Should there be also impressed forces, the actual field will be the sum, in the vector sense, of the two fields, due separately to the electrification and to the impressed forces. Not only that, but the total energy of displacement will be the sum of the amounts in the separate fields; or, the mutual energy of the two fields is zero. This is true because the displacement in the field of the impressed force is everywhere continuous, and the force of the other field wholly polar.

Electrification has no magnetic analogue, the magnetic induction being always continuous. It is important that the distinction between electrification, as above considered, and *imaginary* free electricity (as when the force is discontinuous, though not the displacement) should be clearly recognised. The latter is the analogue of free magnetism.

Similarly, there is no electrification in a conductor supporting a current, provided it be not dielectric as well. In the latter case it is the true current, the sum of the conduction and displacement current, that is continuous, making them sometimes separately discontinuous, thus

$$-\text{div.C} = +\text{div.}\dot{\text{D}} = \dot{\rho}; \quad \text{div.}\Gamma = 0;$$

C being the conduction, $\dot{\text{D}}$ the displacement current, and their sum Γ. It is usually only at the surface of a conductor that there is electrification; should, however, the specific capacity of the conducting matter itself be variable from place to place, there will generally be interior electrification as well, during the existence of a conduction current.

The consideration of the particular kind of dielectric displacement concerned in the phenomenon of absorption must be left over.

(To be continued.)

RECENT ELECTRIC LIGHTING INSTALLATIONS.

It was perhaps with a sense of thankfulness for small mercies that such unwonted interest was manifested in the two papers read before the Society of Telegraph-Engineers and Electricians last Thursday fortnight. So far as they went those papers were satisfactory and encouraging; but they did not, it must be confessed, go very far. Of the two, Mr. Shoolbred's was the most instructive, as was to be expected, Mr. Farquarson's being mainly interesting from the fact that the experimental trials described by him had resulted in a decision which will lead to large Government orders for the electric lighting of a number of Her Majesty's ships of war. There are obvious advantages for the application of electric lighting on board steamships of every kind, and we have always predicted that a wide field for enterprise would open up in this direction when those advantages came to be known. For the mercantile marine there never was a doubt as to the superiority of electricity, when steam power is available, over the oil lamps usually employed, in respect both of cheapness and efficiency. The doubt as to its applicability for the Navy —or rather as to its chances of competing economically in that quarter—has been set at rest by the recent experiments on board the "Colossus," instituted under orders from the Admiralty by Mr. Farquharson.

The doubts to which we have referred were chiefly in regard to the well-known fact that on board Her Majesty's ships of war steam at low pressure is usually employed for economic reasons, and it had been feared that this would prove a most extravagant mode of supplying power to electric lighting Indeed, this was actually seen to be the case by the figures adduced with Mr. Farquharson's paper, some experienced electric lighting engineers pointing out that if the competition had been against a less expensive mode of lighting than that which prevails in such ships as the "Colossus" the experiment must have failed. But it did not fail; on the contrary, it showed that a large, a very large, saving would be effected by substituting electricity for oil as an illuminant, notwithstanding the circumstance that the electric lamps were maintained under the most wasteful conditions—conditions which on land would be fatal to its success as a competitor against any other illuminant whatsoever.

In some other ways the experiment does not appear to have been carried out on very careful lines with a view to economy. This is shown in the number of breakages to lamps, no fewer than sixty-three being destroyed out of a total of four hundred during the short period of seven days. Either there was reckless consumption of energy, or carelessness in the choice of lamps for this installation. But as the cost of renewals was added to the bill, and the average annual outlay based upon the data supplied by the seven days' lighting, the result is all the more favourable to the system. In actual practice dynamos will probably be constructed better adapted for low pressure steam-power, and there will certainly be no such destruction of lamps as occurred on the "Colossus." It follows, therefore, that the result of the trial which proved so satisfactory to the Lords of the Admiralty will be followed by results still more satisfactory, and that their Lordships will have no reason to regret the general introduction of electric lighting throughout the Navy.

The life of the incandescent lamps is a matter of much importance, quite apart from the question of cost. On board these ironclads, for example, which have sometimes been described as iron pots floating with their lids above water, light is required in many parts both day and night continuously, and in all sorts of out-of-the-way spots. Failure of a lamp in these circumstances is highly inconvenient, and might at times be attended with serious consequences. It is reassuring, therefore, to learn, both from the paper which followed on the lighting of the Forth Bridge Works and from the testimony of other experts present, that the failure of an incandescent lamp is generally preventible, the prolongation of its life almost indefinitely being secured partly by better construction, but mainly by the avoidance of currents which tax the filament to its nominal, that is to say utmost, capacity of endurance. Mr. Siemens told the meeting that quite a large number of the lamps originally introduced at the Savoy several years ago were still holding out, and these, of course, were of a pattern which had been greatly improved upon since that theatre was electric-lighted. The improvement in the manufacture of glow lamps in recent years was brought out very clearly by Mr. Shoolbred, who stated that whereas during the first half year's working at the Forth Bridge their average life was 404 hours, it had gone on increasing by improvements and superior workmanship, so that after an interval of barely eighteen months the average life had risen to 1,200 hours. It was also mentioned that a passenger steamship had made the out and home journey to New Zealand with the loss of only one lamp.

Of even greater importance is the continuity of the lighting, whether arc lamps or incandescent are employed, on such works as those now in progress across the Forth. Failure of any of the lights, either by stoppage of the engine or by breakage of wire, would be of serious consequence to the labourers, many of whom are at work below water. But although the installation is on a considerable scale, extending over an area of two or three miles, and the requirements of the most varied character, there has been no failure or mishap

Digitized by Google

whatever from first till now. This we consider most gratifying, as it proves beyond doubt that when, as in this case an installation is put into the hands of competent Electric Engineers, those provoking "accidents" with which the electric light is so frequently taunted will never occur. We note with satisfaction also that the wires at Forth Bridge may be handled with perfect safety. A low E.M.F. has been used in deference, it is said, to the fears of the workmen. We should prefer to describe it as an act of common prudence; anyhow, there will be no accident of the kind which has caused so much terror elsewhere, and it is plain that there never need be any such accident again.

On the whole, therefore, these two installations, for purposes widely differing in character, are full of encouragement, and will be the means of expanding the electric lighting business in new directions, of which business men will not be slow to take advantage. In other directions—for example, in the matter of street lighting, notably in the metropolis—progress is slow; and according to a recent annual report of the Board of Works there has been a "temporary retrogression," owing to circumstances which the Board deplores as much as we do. Its failure to obtain successors to the work undertaken by the now defunct Jablochkoff Company for lighting the Victoria Embankment and Waterloo Bridge is quite intelligible, though the Board think it regrettable. The terms on which these or any other badly lighted localities can be rendered cheerful and safe are such as the Metropolitan Board of Works may, if it chooses, lend its powerful aid in obtaining; and we note as an indication of its willingness to help to this end that it is "making inquiries with reference to the most suitable and economical method of lighting by electricity." Its real difficulty will be to discover the most effectual way to overcome the unnatural obstacles which have been placed in the way of this most "suitable and economical method of lighting."

CORRESPONDENCE.

APPLICATION OF PHOTOGRAPHY TO ELECTRICAL MEASUREMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your edition of yesterday (5th June), under the heading of "Application of Photography to Electrical Measurements," the credit of the idea is given to the Americans. As a matter of fact, I have employed this method myself last year in order to obtain an accurate ammeter recorder (or registering current meter, as these instruments are sometimes called); also for a register of E.M.F. The means employed were very similar to those described, and to obtain the average current or E.M.F. over a given time the curve was integrated by the use of a planimeter.

I had an interview with Mr. Gisbert Kapp (then of Messrs. Crompton) in September last, with a view of making such instruments and others for commercial purposes, but the expense stood in the way.—Yours, &c.,

London, June 6, 1885. DAVID SALOMONS.

BLIND MATHEMATICS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: *Re* the correspondence under the above heading in your last issue, a practical proof may show Mr. Williams the mistake he is making in regarding the expression $\frac{E^2}{R}$ for the rate of development of heat in a wire as fallacious and "deceiving the scientific world."

First, let us say that before we can compare the heat developed in two or more wires by means of their respective resistances we must know whether the current passing through them both is the same, which would be the case if they were connected one after the other in series in a circuit, or whether they are both acted on by the same electromotive force, which would be the case if they were connected in parallel arc, and their combined ends joined to a battery or dynamo.

Take a platinum wire, A, and a silver wire, B, identical in size and length. A has six times the resistance of B.

1. Let the current be the same through both by placing them in series in a circuit. The platinum is heated more than and long before the silver, the heat varying (by $C^2 R$) simply as their resistances, the current being the same in each.

2. Place the wires in multiple arc, and then in a circuit. We have now the same E.M.F. at the terminals of both, and since their resistances are not the same we cannot have the same current passing through each, by Ohm's law the current in B being six times that in A. Now, by the expression C^2R for rate of heating, which your correspondent admits, we have the ratio of the

$$\frac{\text{Heat in A}}{\text{Heat in B}} = \frac{(1)^2 \times 6}{(6)^2 \times 1} = \frac{1}{6}.$$

The silver wire is, therefore, heated first, and six times more than the platinum.

Has Mr. Williams never noticed the difference in brilliancy of glow lamps working in parallel? Which are the brightest? Those of least resistance. If he doubts it let him test them. Or take a more apparent case, thus: while a circuit of Swan 20-candle lamps of, say, 35 ohms each, hot, are running in parallel, let him take one off and put in its place one of the new Edison-Swan 20-candle lamps of, say, 160 ohms hot; the latter would burn dim red if at all, only getting about a third its required current. It would need no "blind mathematics" to see this effect.

If we establish beyond controversy two laws

$$C = \frac{E}{R} \quad \text{and} \quad H = C^2 R,$$

giving the *same* meaning to R in both cases, it is mathematically legitimate to interchange, substitute, or connect these expressions as we like, to form new expressions as correct as the laws from which they are derived.

Blind and groping mathematicians must envy your correspondent his clear vision to see the darkness they are in.—Yours, &c., H. D. WILKINSON,

School of Electrical Engineering, Hanover-square, W.
June 8th, 1885.

ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I should be greatly obliged by your informing me through your correspondence column the greatest length through which electric current has been transmitted for the purpose of electric lighting—I do not mean as a *tour de force*, but for practical, permanent lighting—with the name of the locality where such lighting is carried out.—Yours, &c.,

ADOLPHE DE BROMWERE,
Brussels, 9th June, 1885. Ingènièur Civil, Bruxelles.

ARMATURE WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the comparison between the resistances of the Gramme and Siemens armatures in Mr. Kapp's article on the "Design of Dynamos" (page 23) an incorrect result has been arrived at owing to taking the length of wire on a Siemens armature as $n(b + 1{\cdot}3d)$ instead of $2n(b + 1{\cdot}3d)$.

The difference between the respective lengths of wire on the Gramme and Siemens when the length b of their armatures is the same, would therefore be

$$2n(a - 1{\cdot}3d).$$

Now, if we make the ring and drum armatures identical in diameter and length, wind on the same number of turns on each, and take $a = {\cdot}175d$ the ratio of their respective resistances will be $\frac{{\cdot}175d + b}{1{\cdot}3d + b}$.

Digitized by Google

Hence, if $d = b$ the resistance of the wire on the drum would be nearly double that on the ring, and their resistances would approach equality as b was increased; but it is evident that no relation between d and b would equalise their resistances, for a similar number of turns, so long as the lengths and diameters of their armature cores remained the same.

We may, however, determine their relative economy of winding by the ratio between the number of turns of wire on each necessary to equalise their resistances. This ratio for the ring and drum respectively would be the reciprocal of the last expression.—Yours, &c., H. D. WILKINSON.

NOTE ON THE REGULATION OF DYNAMOS

(Continued from page 60.)

In the former note the condition of regulation was found to be fulfilled when $N b = r$, and it was pointed out that wherever the relations of speed and initial excitation made this possible the machine would give a constant difference of potential at its terminals. This condition is fulfilled in the compound machine at several different speeds, and the machine regulates well at these speeds in consequence; but the speed for regulation is limited on both sides. If the speed is too low the difference of potential at the terminals rises as the current through the lamps increases; if the speed is too high the difference of potential falls as the current increases—in the first case, due to the low initial saturation produced in the

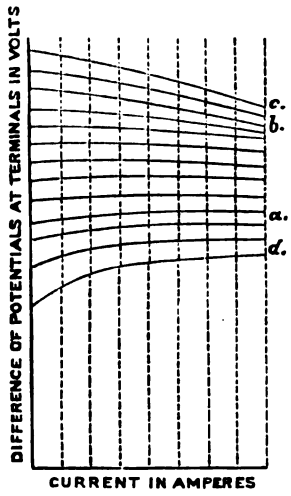

FIG 1.

magnets by the shunt coil $N b$ is greater than r; in the second case, due to the higher saturation produced by the shunt coil $N b$ is less than r. The diagram (Fig. 1) gives a set of characteristics of a compound machine for different speeds, the current in amperes in the outside part of the circuit being represented by distances along the horizontal line, and the corresponding difference of potential at the terminals by ordinates. It will be observed that the regulation is very good for several speeds corresponding to the curves from a to b, but that on each side of these curves the regulation is imperfect. It must be remembered that the rising of the curve at the lower speeds is not purely due to the additional excitement added by the series coil, but that the shunt coil also adds an increased magnetism as the difference of potential at the terminals rises. The effect is, therefore, due to the combined action of the series and shunt coils, although the rise is primarily due to the incorrect adjustment of series to shunt wire at the particular speed at which it takes place.

Referring to the experiment mentioned in the previous article of cutting out the shunt coil, Fig. 2 has been drawn to represent the exact effect produced by running the dynamo at a constant speed, and varying the resistance and consequently the exciting power of the shunt. As before, distances along the horizontal line represent current in the outer part of the circuit, and ordinates the difference of potential at the terminals. Curve a is obtained by cutting out the shunt wire altogether, or by putting into the shunt circuit an infinite resistance, which means the same thing. Curve b is the curve obtained with both series and shunt wire in action, the machine compounding as in the ordinary way. Curves c, d, and e are obtained by introducing into the shunt circuit various resistances, the resistance, of course, remaining unchanged, while the particular curve it corresponds to is being taken. The rise of the curve is in this case also due to the combined action of the series and shunt coils; as the potential at the terminals, due to the action of the series wire, rises, this rise is further exaggerated by an increased current flowing through the shunt coil, but when the shunt coil is excited from a second dynamo and the current kept constant, the same general features are exhibited by the curves.

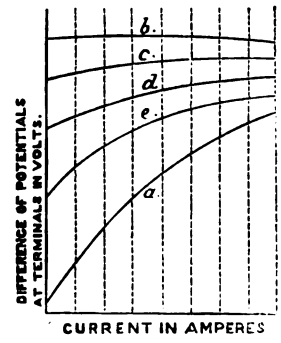

FIG. 2.

These considerations enable us to dispose of some errors which have necessarily characterised our ideas regarding self-regulating dynamos in consequence of our having assumed a straight line law for the saturation of the magnet cores. In a given machine having a certain resistance of armature and series coils and a certain series winding, it has frequently been assumed that if the shunt coil is separately excited by a second dynamo, and the difference of potential varied by altering this excitement, that the regulating speed of the machine remains unaltered. This would mean that the series wire has the same value as far as strengthening the field is concerned, whether the excitement furnished by the shunt coil is great or small, and such a condition can only be fulfilled if the straight line law is true. But no magnet cores in dynamos hitherto constructed are of the dimensions required to render such a law even approximately true, and from the diagram (Fig. 2) it may be clearly inferred that in the case of dynamos where the shunt is separately excited; as the excitement furnished by the shunt is increased or diminished, the speed of the machine must be increased or diminished if it is to regulate at the new difference of potential. This is really what is effected in the compound dynamo for all speeds where the machine regulates. The initial field furnished by the shunt is increased by the rise in speed which is necessary to fulfil the condition of regulation so far as the series wire is concerned.

It may be sometimes necessary to correct inaccuracies in the winding of compound dynamos without going to the trouble and expense of rewinding the machine, and the steps to be taken in order to effect this are indicated in the foregoing observations. Let us imagine that a dynamo has been wound which, *intended* to give a constant difference of potential at the terminals, gives instead a characteristic indicated by curve c. (Fig. 1), where, as the lamps are turned on, the difference of potential at the terminals gradually falls. Now, if the magnetism furnished by the shunt coil were independent of the speed, say as in the Deprez arrangement, where the shunt coil is separately excited, we could, by *increasing* the speed of the machine, straighten the line, whereas in the compound dynamo we can, by *reducing* the speed, do the same thing, as will be seen from Fig. 1. But in either case the difference of potential which would result would be useless for our lamps, assuming that that given by the machine as at present wound is correct when the full current is on. It will not serve our purpose to straighten the line with a reduced potential, but by inserting a permanent resistance into

Digitized by Google

the shunt coil we can bring down the initial excitation, which the curve shows to be too high for regulation, and so make the machine regulate as well as if the series and shunt coils had been properly adjusted to each other in the winding. The speed will have to be somewhat greater that formerly, because the total excitation produced by both coils has been reduced; but the proper speed for regulation may be found by adjusting, by trial, speed and inserted resistance, until the desired effect is produced. By inserting a resistance in the shunt the efficiency of the machine has been increased.

Suppose, now, we have to correct the inaccuracy in a machine where the difference of potential rises considerably as the number of lamps is increased. This case is not so bad as the former, because there is no danger of breaking lamps in reducing their number; indeed it is necessary when running a machine with an engine not otherwise loaded to give a slight rise to the characteristic, so that the slightly increased speed of the engine, due to racing when lamps are turned out, is not a disadvantage. But in the present case we will assume that the rise is excessive, and that the characteristic of the machine is given by the curve *d* (Fig. 1). In the case of a machine having the shunt coil separately excited—the magnetism furnished by the shunt being therefore independent of the speed—the line might be straightened by *reducing* the speed, the potential being necessarily reduced at the same time, whereas in the case of a compound machine reducing the speed would only make matters worse. The line might be straightened in the present instance by *increasing* the speed, only the difference of potential would then be too great for the lamps. Obviously we can only make the machine regulate at the proper potential by increasing the initial magnetism supplied by the shunt coil, and this can be done by reducing the shunt resistance. We must therefore couple the shunt coils in two parallels, introduce a resistance into the shunt circuit, and adjust speed and inserted resistance until the required result is obtained. The regulating speed will be somewhat less than formerly, because the total excitation from both coils has been increased, and the machine may be made to regulate as well as if the series and shunt coils had been properly adjusted to each other in the winding; but in reducing the resistance of the shunt coils the efficiency of the machine has been diminished.

In conclusion, it may be pointed out that much of the reasoning here given is applicable to electro-motors wound differentially for constant difference of potential at the supply mains according to Ayrton and Perry's method. The saturation effect, which enables compound dynamos to regulate at several different speeds within certain limits, should enable compound electromotors to regulate at several different potentials, although running at different speeds. But this can be better discussed in a future paper.

W. B. ESSON.

THE THERMO-ELECTRICITY OF MOLTEN METALS.*

BY F. BRAUN (CARLSRUHE).

1. In a circuit of metallic conductors a current produced by difference in temperature must be the equivalent of heat derived from an external source. If we assume (1) that the process is reversible, (2) that heat is absorbed only at the point of contact of higher temperature, and is given out only at the colder point of contact, then it follows that the thermoelectric force must be proportional to the difference in temperature of the junctions for intervals of any magnitude. If we assume a change in potential function at both junctions, the result may be expressed thus: that the change in potential is proportional to the absolute temperature of the junction. The electromotive force therefore, expressed as a function of the difference of temperature, ought to be a straight line. But experiment shows that in all the thermopiles as yet examined this linear relationship does not hold good; in by far the majority of cases the curve is much nearer a parabola. This led Sir W. Thomson to the conclusion that even in the interior of one and the same metal unequally heated there must be produced, upon the passage of a current, a quantity of heat proportional to the first power of the current strength (adopting Le Roux's term, we may call this "the Thomson effect").

In fact, if the thermopile works, not between two temperatures, but between an infinite number, it follows inversely that its electromotive force can no longer be expressed as a linear function of the greatest temperature difference which occurs in it. Although, strictly speaking, nothing can be determined as to the locality of the electromotive force, yet we should be disposed to add to the changes in potential assumed to exist in the junctions (of which, however, no proof has yet been given that they occur there) other changes of potential occurring in the interior of the unequally heated metal.

Hitherto, so far as I know, only thermopiles have been examined in which at least one metal has been solid. The explanation is then obvious, that these internal thermoelectric forces are due to changes produced by the heat itself in the solid metal—hot and cold metal behaving like two different substances, or, as we may shortly express it, the heat produces structural changes. In fact, as shown by the experiments of Magnus, pieces of the same metal but of different temperature produce a thermoelectric current when brought quickly into contact. Only with lead could this result not be observed with certainty. But in lead, as Le Roux showed, the Thomson effect is nearly or quite zero. In general, those metals which show a large Thomson effect show also the further peculiarity that, upon heating a single wire the ends of which are kept at a constant temperature, a thermoelectric current is produced, the intensity (and even direction) of which often varies with insignificant changes in the distribution of the temperature or the structure of the wire.

These currents, I may at once mention, are so energetic, and especially so variable, particularly if the temperature is raised to a red heat, that I have had to take precautions with my thermopiles that there should not be any great differences of temperature in the solid metal. With lead only have I been unable to observe with certainty any such currents, even when the solid metal was plunged into molten lead. According to an experiment of Magnus's, often quoted, which for short I will call the Magnus experiment, currents are altogether absent in mercury.

It is an obvious explanation to refer the currents, produced on bringing together a cold and hot metal, to differences in structure (although we must then ascribe some influence either to time or to distribution of temperature), and to class them together with the Thomson effect—that is, the deviations which the thermoelectric force shows from proportionality with the temperature-difference. If certain metals give no thermo-current either in the Magnus experiment or when a wire, whose ends are maintained at a constant temperature, is heated, this may be explained in two ways: either changes of potential take place on both sides of the point heated, which, however, must decrease equally in both directions, or no thermoelectric excitation takes place, because, in consequence of the nature of the metal, differences in structure are impossible.

To this latter, although more special, assumption it seems to me we shall be most inclined. It is to be assumed that other molten metals will behave as mercury does, which, in fact, I have found to be the case (*cf.* § 7).

2. If we regard the Magnus experiment in this second way, it would follow that the thermoelectric force between molten metals must be proportional to the difference in absolute temperature between their points of contact. But this would show the possibility of measuring absolute temperatures to a very high point by a method presenting many advantages over measurements made with an air thermometer (smaller space of constant temperature, independence of expansion and changes in form of the vessel). We should further, and probably for the first time, obtain numbers which are entirely dependent upon the chemical nature of the substance, and free from uncertainties as to how hard or soft the body is. They would offer us a more ready conclusion as to the internal processes by which thermoelectric forces are excited. In fact, it appears very remarkable how,

* From the *Phil. Mag.* for June. Translated from the *Sitzungsber. der königl. Akad. d. Wissensch.* of Berlin, of April 9th, 1885.

Digitized by Google

under similar external conditions (where any desired quantities of heat are available), large quantities of heat are transformed into the form of energy of mechanical work, at the points of contact of many metals, and with others very small quantities.*

Since, further, each molten metal in thermoelectric relationship must be characterised by a single constant (which no doubt may vary with the pressure), this must stand in some relationship to other constants, characterising the particular metal, and independent of the temperature; but of such there is only the atomic weight available.

3. These considerations induced me to measure the thermoelectric forces of molten metals against each other between as wide limits of temperature as possible. A linear dependence upon the temperature appeared to me *à priori* so probable, that I directed my attention from the first to the utmost possible chemical purity of materials, and, moreover, chose only elements. Alloys were investigated only in the second place.

In the following I give the combinations which were measured, as well as the range of temperature employed; t denotes the temperature of the colder points of contact, T the highest reached at the warmer point of contact.

NaHg ..... $t = 20°$ or $100°$; $T = 370°$.
PbHg ..... $t = 20°$; $T = 580°$.
KHg ..... $t = 20°$ or $100°$; $T = 520°$.
SnHg ..... $t = 20°$; $T = 460°$.
Hg(Na + K†) . $t = 20°$; $T = 380°$.
PbSn . . . . $t = 20°$; $T = 435°$; $t = 424°$; $T = 974°$.
BiSn . . . . $t = 508°$; $T = 882°$.
Hg(Hg + Bi + Pb)‡ $t = 20°$; $T = 530°$.

4. For the determination of high temperatures in spaces frequently small I employed spirals of platinum wire, whose galvanic resistance had previously been determined as a function of the temperature. I employed for this purpose a large muffle furnace heated by coal, the description of which, as well as of other experiments made with it, I propose to give shortly elsewhere. The vessels for the air-thermometer were made of Meissen porcelain.§ The dimensions could be so chosen that, assuming constancy of temperature, temperatures of 1,000° C. could be accurately measured to 1° or 2°.

5. The metals were enclosed in glass tubes, wherever glass could be used. Platinum wires melted into the glass served for external connections. With some metals the platinum wire was in direct contact with the metals; with others this contact was made by means of a pencil of retort-carbon‖ or graphite, with others by means of an iron wire. Two glass tubes filled with metal were placed vertically side by side. At the hotter (upper) point of junction the platinum wires were melted together outside the tubes by means of the oxy-hydrogen blowpipe. So far as the wires which serve to make contact with the fluid metal at the hottest and coolest points penetrate the ends of the tubes, uniformity of temperature must be maintained. The cooler (lower) ends of the tubes were plunged into two concentric vessels full of mercury, which were placed in a bath of constant temperature, though not always the temperature of the room. From these mercury vessels wires of lead conducted to a petroleum bath of the temperature of the room, from which the copper connections were made. The leaden wires of course could not be placed directly in contact with the mercury. Their ends were melted into a glass tube, through the lower closed end of which a short platinum wire passed. I pass over here the precautions found necessary in order to ensure that the other portions of the circuit should be affected only by slight thermoelectric forces, which remained constant for a considerable time and which were separately determined. The electromotive forces were measured by compensation.

6. The temperature of the hotter point of contact was maintained:—(1) In a bath of mineral oil of high boiling-point, which was kept agitated by a stirrer. In this way a temperature of about 380° C. could be obtained. (2) In an air-bath, consisting of three concentric iron cylinders, surrounded on the outside by a jacket of iron and chamotte, which was constructed according to my designs for another investigation, and which Ehrhardt* has recently described. It was heated by means of gas, and permitted the attainment of a temperature of 580°. (3) By a brisk current of vapour of constant boiling-point, sent through a glass vessel protected against external radiation of heat. The substances employed were alcohol 80° C., water, xylol 140·5° C., aniline 183° C., dimethylaniline 192° C., toluidine 198° C., xylidine 214° C. In order to decide with certainty particular questions I required constant temperatures, not differing much from each other. For the control of other measurements, I further employed baths of vapour of benzoic acid 250° C., mercuric iodide 357° C., and sulphur 448° C. For still higher temperatures (up to 980° C.) I employed (4) a muffle. The vessels which contained the metal were of earthenware. Imagine an earthenware tube inclined some 10° to the horizontal plane, and provided at both ends with vertical pipe-heads. Two such tubes of equal length were placed side by side. Each contained a molten metal. The upper pipe-heads were within the muffle, and heated to a higher temperature than the lower ones. They were connected by a bridge of thick iron wire or of retort-carbon, by means of which a wide thick-walled chamotte-neck passed from the muffle through the heating-channel outwards, through which the earthenware tubes passed; the other two pipe heads were outside the muffle, surrounded by an iron box, which was heated by coal. The temperature then was maintained as close as possible to the melting point of the more difficultly fusible metal. In order to carry the circuit from the molten metal outside the muffle, previous experience had shown lead to be the only available metal which permitted the reduction of temperature to that of the room. The following arrangement was adopted in view of its properties:—At the lower end of a thin walled brass tube of about 12mm. diameter an iron tube was brazed; it was closed below by an iron disc screwed on, to the inside of which a piece of platinum foil was soldered. The screw closed against the molten metal in which the iron tube plunged. A platinum wire was in contact with the platinum foil. This was melted through the closed lower end of a glass tube. The bottom of this was filled to a height of about 10 mm. with graphite. Lead wire was pushed slowly into the glass tube, which melted and formed a continuous connection from the molten to the solid lead. The solid lead wire conducts again to points at the temperature of the room. All the different conductors (iron, platinum, and graphite) were completely surrounded by the molten metal in the pipe-head, which stood some 4 cm. above the top of the graphite layer. We may therefore assume equality of temperature in all. This last-described arrangement was employed for the circuits PbSn and SnBi.

7. I pass now to the results obtained. If we take the temperatures as abscissæ and the electromotive forces as ordinates, the following results are obtained. Most, if not all, the curves are not actually straight lines; they are of such a form that the centre of curvature lies on the side of the curve turned away from the axis of abscissæ, *i.e.*, the electromotive forces increase more rapidly than corresponds to proportionality with the temperature. Only the curve for NaHg, which is almost straight for a considerable distance, seems at higher temperatures to assume a curvature towards the other side. The thermoelectric force of this element is, however, so small that measurements with it offered special

* That we may regard the Peltierian heat as the equivalent of the work which the electricity does in passing to a lower potential-level at the points of contact, requires no justification. The work lost at the one contact-point can be restored by the equal amount gained at the other, just as the quantities of work in the portions of the two arms of a siphon at equal heights compensate each other. We cannot conclude anything, as Maxwell has done, as to the difference of potential produced, as a result of contact-electricity, from the Peltierian heat at the point of contact of two conductors.

† Alloy liquid at ordinary temperatures; about 1 eq. K to 1 eq. Na.

‡ Alloy liquid at ordinary temperatures; 1 part lead, 1 part bismuth, 3 parts mercury.

§ I wish here to express my obligations to the Royal Saxon Porcelain Manufactory, and especially to M. Büttner, for the great trouble which they have taken in the very difficult manufacture of these vessels.

‖ Platinum at 200° is amalgamated by mercury, and at about 500° is dissolved as energetically by mercury as it would be by boiling aqua regia.

Digitized by Google

difficulties. KHg is almost a straight line, but possesses certain peculiarities (see below).

The curves are certainly not of the second degree, but of the third at least. Tait's assumption that specific heat of electricity is proportional to the absolute temperature, which would lead to the equation to a parabola, therefore does not hold good for molten metals. I give here a few numbers from the curve for the element PbHg. It is

TABLE I.

Lead-Mercury.

	θ	ρ.	$\frac{de}{d\theta}$		Π calculated.

of especial interest, on account of the property of lead, not to give any Thomson effect. The first column gives the temperature of the warmer point of contact in centigrade degrees, the second the same reckoned from absolute zero. The temperature of the other point of contact is throughout 20° C. The third column contains the electromotive force e in micro-volts. If e is a function of θ, represented by a curve of the second degree, then $\frac{de}{d\theta}$ ought to be a linear function of θ. The fourth column shows the observed valne of $\frac{de}{d\theta}$, and the fifth the value calculated from the first two numbers of the fourth column. The differences are far greater than possible errors of observation. The last column gives the quantities of heat in gramme-calories which result at the point of contact of absolute temperature θ, when the quantity of electricity electro-chemically equivalent to 2 grammes hydrogen (193,000 coulombs) passes through.

If we conclude from the experiments of Le Roux (who, however, gives no absolute value of the Thomson effect) that there is no Thomson effect in lead, there must be such in mercury. Moreover its magnitude must be considerable. This follows from the observations with the couples HgCu, HgPt, HgFe, whose electromotive force I have measured for considerable differences of temperature. The Thomson effect is very considerable in the metals Cu, Pt, Fe; in mercury it must be at least of equal magnitude according to the results of these measurements.

The wires employed of the three metals when heated in the middle, whilst the ends were maintained at constant temperature, gave very considerable electromotive forces (70 to 200 microvolts) even after they had been repeatedly heated. Mercury, on the other hand, as is well known, gives none. This last phenomenon and the Thomson effect cannot therefore stand in any direct connection.

In the thermo-element PbHg, the contact points may have the respective absolute temperatures Θ and θ ($\Theta > \theta$); it may be supposed to remain closed so long that its thermo current has conveyed the electro-chemical unit of electricity through it. Then at the temperature Θ the quantity of heat Π_Θ is absorbed, and at θ the quantity of heat Π_θ is given off to surrounding objects. The difference $\Pi_\Theta - \Pi_\theta$ in the present example cannot be completely converted into electrical energy (with an oppositely bent curve it would not be the only equivalent), but there would be also heat from the interior of the metals themselves converted into work.

The following Table II. gives for different intervals of temperature the heat $\Pi_\Theta - \Pi_\theta$ in gramme-calories. Further, the electrical work L in the same units. The result is that in the most favourable case 47 per cent. of the heat $\Pi_\Theta - \Pi_\theta$ appears as useful electrical work. The remainder, at least 53 per cent., remains in the metals themselves, in the form of (reversible) heat. It is given in the fourth column.

The thermopile absorbs the quantity of heat Π_Θ at the highest temperature Θ; at least, the pile works with this heat-capital. How much of this heat appears as useful work? The sixth column shows that it is at the outside 40 per cent. If of the quantity of heat Π_Θ the whole remainder not converted into work at the temperature θ were given off, the fraction $\frac{\Theta - \theta}{\Theta}$ must be converted into current energy. The next column shows this fraction.

TABLE II.

Temp. interval.	$\Pi_\Theta - \Pi_\theta$.	Elec. work, L.	$\Pi_\Theta - \Pi_\theta - L$, or Heat in metals.	$\frac{L}{\Pi_\Theta - \Pi_\theta}$	$\frac{L}{\Pi_\Theta}$	$\frac{\Theta - \theta}{\Theta}$	$\frac{\Pi_\Theta - \Pi_\theta}{\Pi_\Theta}$
20–100	36·8	15·8	21·0	0·43	0·19	0·21	0·44

If we now enquire whether thermo elements are suitable arrangements for converting heat into work, we obtain the following result:—Elements for which the electromotive force increases greatly with rise of temperature, as is the case for the element HgPb, work with very small useful effect (not regarding the loss of heat by conduction, radiation, &c.). Thermo elements whose electromotive force decreases with rise of temperature work with more useful effect, but contribute absolutely less towards the work to be done.

Other elements with liquid metals give essentially the same results as the PbHg element. The curve for Hg(Hg + Br + Pb) has nearly the same form. In this combination both constituents are fluid at ordinary temperatures: I have examined them for an interval of more than 500°. It appeared to me of particular interest to repeat Magnus's experiment with this fluid alloy. If a portion of the amalgam was plunged cold into the rest heated to about 300°, no thermo-current was produced the electromotive force of which exceeded 0·5 microvolts, which was the lowest I was in a position to measure.

The curve for this element shows a remarkable peculiarity. At 180° it is convex towards the axis of abscissæ, but between 180° and 210° it becomes concave, and then again convex. In this respect it is qualitatively exactly like the curve which platinum-iron elements give, only that in the latter the peculiarity is more decided. With a PtFe element the curve rises steeply to about 360° and somewhat concave towards the axis of abscissæ, then bends rapidly towards the horizontal direction, having a maximum at 420°, then falls from this very little (almost horizontal) to a minimum at 520°, rises then slowly, and then from about 630° ascends again to 1,000° as steeply as from 0° to 36°.

The element consisting of molten potossium and mercury shows an exactly similar behaviour, the curve rising with oscillations. Consistent results are, however, only obtained with this latter element when vapours of constant boiling-point are employed as source of heat. Using the oil-bath or the air-bath, the values obtained at the same temperature often vary considerably.

We shall probably only be able to explain these phenomena by the assumption that molecular transformations take place also in liquid bodies (as is known to be the case, for example, with sulphur); and these changes appear, at least as far as their velocity is concerned, to depend on the rate of heating. The question then suggests itself whether molten cadmium, which in the form of vapour is monatomic, combined with a thermo-element with the similarly constituted mercury, would show linear dependence of electromotive force upon temperature.

The interval of temperature available seemed to be too small to determine this point with certainty; and I considered it beside the mark to employ cadmium amalgam, since we could no longer assume the existence of isolated atoms.

Digitized by Google

8. Taking all the results together, we may come to the conclusion that in thermoelectricity we are still further from an insight into the true nature of things than most physicists have supposed. We must assume the existence of electromotive forces even in the interior of molten metals of unequal temperature; and, moreover, these follow no simple laws. It would not be difficult to find formulæ for the electromotive forces supposed to exist in the interior of metals which should satisfy the observations; but it seems to me that we do not thereby come nearer to a representation of the processes which occur. We may say with certainty that fluid unequally heated metals are electrically charged, and that by simple inequalities of temperature in a conductor the conditions for transformation of heat into work are fulfilled, only that we cannot obtain the work in the convenient form of a closed current. Perhaps this excitation of electricity takes place in all fluids, and generally in all substances, *i.e.*, also in the so-called vacuum; and the further question, important in principle, may arise, what influence this hitherto disregarded circumstance has upon physical processes.

If we return to the facts detailed above, everything indicates that thermoelectric excitement is an intermolecular process dependent upon the number or arrangement of atoms in the molecule. It is thus suggested that all the rough mechanical changes, which exert so much influence on the thermoelectric behaviour of a solid body, and which consist in drawing, bending, hardening, annealing, &c., are also connected with intermolecular, and thus in a measure chemical, changes. This would be in harmony with the one already known fact, that in steel, upon passage from the soft into the hard condition and *vice versâ* (also by simple drawing), the quantity of chemically combined carbon changes. Hard and soft steel give, as is well known, a tolerably powerful thermoelectric action.

CITY AND GUILDS OF LONDON INSTITUTE.

22C.—Electrical Instrument Making.

INSTRUCTIONS.—This examination is for the purpose of ascertaining whether the candidate has intelligently noted the methods employed in the workshop in the construction of electrical apparatus, and whether he has endeavoured to ascertain the scientific reasons for the processes followed. The candidate must confine himself to one grade only, the ordinary or honours, and must state at the top of his paper of answers which grade he has selected. He must not answer questions in more than one grade. If he has already passed in this subject, in the first class of the ordinary grade, he must select his questions from those of the honours grade. The number of the question must be placed before the answer in the worked paper. Three hours allowed for this paper.

ORDINARY GRADE.—[Candidates are not to answer more than two out of the first three questions, and not more than seven altogether.]

1. Explain exactly what is meant by saying that the electric resistance of a given wire is constant for the same temperature, and independent of the current passing through the wire.

2. A battery is sending a current through a wire; if this wire be gradually made shorter and shorter, describe what changes will take place (1) in the current, (2) in the potential difference at the terminals of the battery, and (3) in its electromotive force.

3. Define fully an ampere, an ohm, and a volt. What current will 15 cells, each having an E.M.F. of 1·07 volt and an internal resistance of 0·7 ohm, send through an electro-magnet having 28 ohms resistance, when the electro-magnet is shunted with a wire having 7 ohms resistance?

4. Give a description, with drawings, of a high resistance astatic reflecting galvanometer, with high insulation in all parts.

5. Give a description, with drawings, of the construction of a differential galvanometer. Describe fully the mode of adjusting the two coils, so that they may have equal resistance, and also equal magnetic effect.

6. Describe, with detailed drawings, the best form of "influence machine" with which you are acquainted, and explain the principle of its action.

7. How would you make a cheap resistance, the magnitude of which could be altered at will, to be used for strong currents? Give a drawing of the details, and a specification for the guidance of the maker.

8. Write out a specification of a good form of cheap electric trembling bell. What kind of cells would you use for bells, and why?

9. What are the conditions to be fulfilled in a key to be used with a Wheatstone bridge? Describe fully a simple form of key fulfilling these conditions.

10. Describe, in detail, the construction of a permanent magnet, mentioning the brand of steel to be used, and the country from which it should be obtained, the size and shape of the piece of steel employed, the mode of hardening, tempering, and of magnetising.

11. Explain the various shapes it would be desirable to give to the pole pieces of an electro-magnet, so as to obtain the maximum effect in various cases. State fully under what circumstances you would adopt each shape.

12. Give a drawing of a shunt box having high insulation. Prove what should be the resistance of three shunts, so that 1-10th, 1-100th, and 1,1,000th of the total current will pass through a galvanometer of 8,600 ohms resistance. What kind of wire would you use for the shunts, how would you wind it, and where would you place it to diminish the temperature error as much as possible?

13. In the construction of resistance boxes, what should be the relative diameters of the wires used in making the 1 ohm and the 1,000 ohm coils? Give full reasons for your answer.

14. Describe, with drawings, a telephone transmitter and receiver. Explain fully why an induction coil should be used with the transmitter when the length of the telephone line is considerable.

15. Give a drawing of a good switch for an incandescent lamp, and mention what are the characteristics of a good switch for this purpose.

16. You are required to solder together two copper wires in a galvanometer. What flux would you use and why? Give a sketch of the joint you would make, 1st, if the copper wires were thin, 2nd, if they were stout wires.

17. Two electro-magnets having iron cores and bobbins of exactly the same size and shape are wound, the one with a copper wire 0·01in. diameter, the other with a wire 0·02in. diameter, so that the external dimensions of the bobbins, when wound, are also the same in both cases. Calculate the relative strengths of the currents required to be used, so that the strength of the two electro-magnets may be the same.

HONOURS GRADE.—[Candidates are not to answer more than one out of the first three questions, and not more than seven altogether.]

1. Explain exactly what is meant by saying that the electric resistance of a given wire is constant for the same temperature, and independent of the current passing through the wire.

2. A battery is sending a current through a wire; if this wire be gradually made shorter and shorter, describe what changes will take place (1) in the current, (2) in the potential difference at the terminals of the battery, and (3) in its electromotive force.

3. Define fully an ampere, an ohm, and a volt. What current will 15 cells, each having an E.M.F. of 1·07 volt and an internal resistance of 0·7 ohm send through an electro-magnet having 28 ohms resistance, when the electro-magnet is shunted with a wire having 7 ohms resistance.

4. Describe, in detail, giving sketches, some form of apparatus especially adapted for measuring small resistances, and prove the formula employed in using the instrument.

5. Describe, in detail, giving sketches, an apparatus which may be used for measuring, with one observation, a resistance when a strong current is passing through the resistance, and show exactly how it is employed when used to measure the resistance of the electric arc.

6. Describe the theory and practical construction of a "constant current shunt," that is, one which shunts the current passing through the coils of a galvanometer, without altering the total current flowing in the circuit. Give an actual example of the numerical working out of the proper values to give to the coils of a constant current shunt.

7. Give a detailed account of some instrument used for measuring large currents in amperes, and of some instrument for measuring large potential differences in volts. Explain fully why a change of temperature may seriously affect the sensibility of the latter, while it produces, practically, no variation in the sensibility of the former.

8. Give an account, together with detailed sketches, of the apparatus employed in duplex signalling on a long submarine cable.

9. A horseshoe electro-magnet has two bobbins, each 2in. long and ⅞in. external diameter. If the diameter of the iron core is ¼in., the resistance of the remainder of the circuit 420 ohms, and the resistance of a cubic inch of pure copper 0·63 microhm, what should be the diameter of a copper wire having 94 per cent. of the conductivity of pure copper, to be wound on the electro-magnet, if the thickness of the silk be neglected? In what sort of way would you modify your answer to allow for the space occupied by the insulating covering?

10. Give a description, with detailed sketches, of a non-sparking key.

11. Certain specimens of soft iron, to be used for the cores of electro-magnets, are given you to examine. Describe, in detail, the kind of tests you would make to ascertain which specimen of iron was the most suitable for the purpose.

12. Describe, in detail, the mode of absolutely calibrating a current meter without the employment of any standard current meter.

13. Describe, in detail, the mode of absolutely calibrating a potential difference galvanometer, without the employment of any standard potential difference meter.

14. Calculate the size of plates that must be separated by a layer of air 0·01 inch in thickness, so that the air condenser may have 0·0001 of a microfarad capacity. One farad corresponds with about 10^{12} C. G. S. electrostatic units of capacity. About how much per cent. would your answer be altered if the air were replaced with paraffin wax?

15. Give a full description, with drawings, of a reflecting galvanometer for measuring capacity. What are the essential features of such a galvanometer?

LEGAL.

Re the Companies Act and in re the Brazilian Submarine Telegraph Company.

This was an appeal before Mr. Justice Grove and Mr. Justice Denman from an order made by Mr. Justice Mathew at Chambers, under sec. 35 of the Companies Act, 1862, by which a remedy is provided for the rectification of any improper entry or the omission of any entry in the register of the members of any company. The facts in the case were shortly as follow:—Madame Chatenay, of Rio, was at the time of her death the registered holder of 50 shares in the Brazilian Submarine Telegraph Com-

Digitized by Google

pany. After her death in 1881, her son, Mr. Emilio Chatenay, instructed a Mr. Broe, resident in this country, to obtain letters of administration for him to his mother's estate. He sent Mr. Broe a power of attorney in Portuguese, by which, as appeared from the translation, he (Mr. Broe) was "especially to buy and sell shares of public companies and receive any dividends and to give receipts in conformity with his (Mr. Chatenay's) instructions." Mr. Broe sold the 50 shares in the usual way on the London Stock Exchange, and the transfers were signed by him in the name of Chatenay under the power of attorney which he held. Mr. Chatenay now denied that Mr. Broe had had any authority to execute the transfers, and he called upon the company to rectify their register by restoring his name to it as the holder of the 50 shares. They having refused to do so he had taken out a summons under section 35 of the Companies Act, 1862, which is as follows:—"If the name of any person is without sufficient caused entered in or omitted from the register of members of any company under this Act, he may, by motion in any of Her Majesty's superior courts of law or equity, or by application to a judge sitting in chambers, apply for an order of the Court that the register may be rectified; and the Court may either refuse such application . . or it may, if satisfied of the justice of the case, make an order for the rectification of the register and may direct the company to pay all the costs of such motion and any damages the party aggrieved may have sustained; the Court may in any proceeding under this section decide on any question relating to the title of any person who is a party to such proceeding to have his name entered in or omitted from the register, whether such question arises between two or more members or alleged members or between any members or alleged members and the company, and generally the Court may in any such proceeding decide any question that it may be necessary or expedient to decide for the rectification of the register; provided that the Court, if a Court of common law, may direct an issue to be tried." Mr. Justice Mathew, confirming an order of a master, directed an issue to be tried between Mr. Chatenay and the company, and the latter appealed against that order.

Mr. FINLAY, Q.C. (with whom was Mr. E. B. Calvert), for the company, contended that they ought not to be forced, as they were by the order, to fight an issue in which they had no interest. Mr. Chateney sought to affirm the transfers to himself executed by Mr. Broe, and disaffirm the transfers to the holders of the 50 shares executed on his behalf by Mr. Broe as his duly authorised agent. He said that Mr. Broe had no instructions either to accept or execute transfers, and that the English translation of the power of attorney which had been given by him to Mr. Broe was incorrect. The company did not object to the trial of an issue as to the registration of the 50 shares that had belonged to Mr. Chatenay, but they contended that it should be between him and the transferees. He (the learned counsel) did not contend that Mr. Justice Mathew had not had discretion to make the order, but he submitted that his discretion ought to be overruled, as the company ought not to be made the defendants in the issue.

Mr. Justice DENMAN asked if it was not more convenient that the issue should be tried than that the company should not be made defendants in an action.

Mr. FINLAY said if there were an action an order would be made bringing in the transferees as third parties to it. If the company were made defendants in an action they would have a right to claim an indemnity from Mr. Broe for having furnished them, if he had done so, with an incorrect translation of his power of attorney. It was his duty not to have misled them, and so caused them to register the transferees of Mr. Chatenay's shares. In an action brought in the Chancery Division by the Rio de Janeiro Gas Company against Mr. Chateney, where the question was as to the validity of the transfer of certain shares in that company under similar circumstances, a summons had been taken out by him (Mr. Chateney) in the Queen's Bench Division. This had been transferred to the Chancery Division, and there the Court directed an issue to try the question whether the shares were lawfully transferred, whether the transferee from Mr. Broe or Mr. Emilio Chatenay was the owner of the shares in question, and whether Mr. Chatenay was entitled to be on the register in respect of such shares; and the defendants were to have the same right as regards discovery as if an action had been brought by Mr. Emilio Chatenay against the said company and Mr. Oxley, the transferee. The learned counsel submitted that a similar order ought now to be made in this case. It was the more important to bring in the transferees at the trial of the issue, as, if it were decided in Mr. Chatenay's favour, that would not decide the question as between the transferees of the shares and the company. The transferees ought, as he contended, to have liberty to attend the trial and cross-examine the witnesses, but should be bound by the result. At any rate, the trial of the issue should be stayed until the question as between Mr. Chatenay and the transferees of his shares had been decided.

Mr. Gainsford Bruce, Q.C. (with whom was Mr. H. D. Greene), appeared for Mr. Chatenay, but was not called upon to argue the case.

The Court dismissed the appeal, holding that upon the whole of the facts the trial of an issue was the best mode of deciding the question in the case, as it was clearly distinguishable from one in which two persons set up a claim against each other to be placed on the register of a company. It was just possible that the defendant company might have placed the names of the transferees of Mr. Chatenay's shares on their register without proper authority, and that question ought first to be decided. The matter was still left open to the company in the sense of their being able to bind those persons whose names were actually on their register as the owners of the 50 shares. In order that the company (the defendants in the issue) should be in the same position as if an action had been brought, Mr. Justice Mathew had reserved to them all their rights. Appeal accordingly dismissed, with costs.

COMPANIES' MEETINGS.

Provincial (Brush) Electric Light and Power Co.

An extraordinary general meeting of the shareholders of this Company was held at 68A, Cow Cross-street, E.C., on the 11th inst., under the presidency of Mr. T. Fry, to consider the following resolutions:—

"(1) That the Company be wound up voluntarily, and that Mr. William Henry Pannell, of 38, Basinghall-street, London, chartered accountant, be appointed liquidator for the purposes of such winding-up. (2) That the shares held by the above-named Company in the Consolidated Electric Company (Limited), under an agreement dated the 9th day of March, 1883, and made between Joseph Samuel Beeman of the first part, William Taylor of the second part, Frank King of the third part, the South-Eastern (Brush) Electric Light and Power Company (Limited) of the fourth part, the Provincial (Brush) Electric Light and Power Company (Limited) of the fifth part, and the Consolidated Electric Company (Limited) of the sixth part, be not sold, but distributed among the shareholders in the above-named Company, share for share. Provided always that no shareholder in the above-named Company who shall be in arrear with respect to payment of calls shall be entitled to receive such shares until all such arrears shall be paid, but that such shares shall be held by the liquidator in the meantime, and if such arrears be not paid within a reasonable time, shall be sold by him as though this resolution had not been passed. (3) That the liquidator be requested, authorised, and empowered to carry out the said resolution."

The SECRETARY read the notice convening the meeting as above.

The CHAIRMAN said: Gentlemen, we ask you to-day to accept the inevitable. We have long seen—as many of the shareholders have—that being deprived of the means of carrying on a business which might have become profitable, the end must sooner or later arrive. The only difference between us was this—when we should terminate the existence of the Company. I think that we, sitting on this side of the table, and having a complete knowledge of the inner life of the Company are better able to judge when we shall bring it to a close than those who have not had the same opportunity. Since we met in January very much has been done to improve our prospects, especially in connection with the Consolidated Company, and we now see that we can terminate the existence of the Company and still preserve something to the shareholders. He concluded by proposing the first resolution.

Mr. WAPSHARE seconded the resolution.

Mr. J. B. BRAITHWAITE asked whether the Chairman had considered the suggestion made on behalf of the majority of the shareholders, namely, that Mr. Stewart should be joined with Mr. Pannell as co-liquidator.

The CHAIRMAN stated that the Directors were not aware of any suggestions which had been made on behalf of the majority of the shareholders.

Mr. BRAITHWAITE asserted that at the last meeting he and those with whom he was acting polled two to one. He wished, at all events, to know whether the Directors would accede to the demand that the shareholders should be represented on the liquidation.

The CHAIRMAN replied in the negative, and stated that they had been advised that they could not. They gave the shareholders an opportunity when the liquidation was first talked of of joining with them—that was one Director and Mr. Stewart; but behind their backs an attempt was made to appoint two shareholders to wind up the Company, instead of one Director and one shareholder. To avoid any complication of that kind on the present occasion they determined that the matter should be left to some one entirely independent of the Company, and surely the matter might be left to Mr. Pannell.

Mr. BRAITHWAITE said that he and his friends had done all that they could in the past to put a stop to the reckless extravagance and waste of their money, and they had received great support from the shareholders. Notwithstanding that fact, they had heard the distinct avowal of the Chairman that he would not allow the shareholders to be represented on the liquidation, especially with such Directors as they had had, whose past conduct could not, he maintained, be considered free from blame. He therefore moved an amendment to the effect that the Company be wound up voluntarily, leaving the question of the appointment of liquidators to a separate resolution, or even to a subsequent meeting. He thought it would be most suicidal to entrust to the nominee of the Directors the whole of the carrying out of the liquidation, which would give to that gentleman full powers to call up the whole of the remaining capital, and to quash all matters connected with the Consolidated Company, the history of the formation of which was, he said, still involved in great obscurity. It was only fair that the shareholders should be represented on the liquidation, and they proposed that Mr. C. H. Stewart, a member of the Corporation, and a gentleman of high position, should be appointed for that purpose to act with the gentleman nominated by the Directors.

Mr. BURT (the solicitor) said he had been obliged to advise the Chairman that, as a matter of law, it was impossible to alter the resolution or put any amendment to it. The meeting could only pass it or reject it.

Mr. BRAITHWAITE stated that he had been advised that his amendment was perfectly in order, and that the course he suggested had been acted upon on several occasions.

Mr. BROOKER seconded the amendment.

The CHAIRMAN said they had heard that he could not put the amendment. [A Voice: "Another shuffle."] The Directors did not desire to have anything to do with the liquidation. They were acting, as they believed, in the interests of all, and they drew no distinction between those shareholders who were supporting them and those who were in favour of Mr. Braithwaite. All that they desired was to save as much as they could for the Company; and in time they might possibly—if the Consolidated Company prospered as he believed it would—get a very con-

Digitized by Google

siderable return. For their present purposes, however, they wanted to wind up, and as quickly and cheaply as possible; and by employing Mr. Pannell the matter would be left in the hands of one man, whose experience would enable him to deal with the assets of the company and turn them to the very best account, and no time would be wasted in conferring with other liquidators. He declined to put the amendment, as no notice had been given of it.

Mr. BRAITHWAITE said, in face of the ruling of the Chairman, he would move the adjournment of the meeting for a fortnight, in order to give the necessary notice.

Mr. BROOKER seconded the motion.

The CHAIRMAN put the resolution, and announced that there were 11 for it and three or four against it; but he would now demand a poll.

Mr. BRAITHWAITE said that there were 11 for his motion and three against it, two of whom were Directors, and yet the Chairman demanded a poll, knowing that he (the speaker) and his friends had not sent out any proxies.

[A VOICE: "Another shuffle".]

The CHAIRMAN said his desire was to save the shareholders time and trouble. He could tell the shareholders that it was perfectly impossible for Mr. Braithwaite to get a sufficient majority to wind-up the Company without the assistance of the Board. If things were brought to a deadlock, the Directors would have to go on with the business, and they could not do so without making calls. They had nothing whatever to conceal.

The poll was then taken, and

The CHAIRMAN stated that the result was as follows:—17 shareholders, holding 930 shares, had voted for Mr. Braithwaite's proposition, and 128 shareholders, holding 3,849 shares, had voted against it. That was including the proxies. He then put the original resolution, which was again lost on the show of hands, a poll being again demanded.

Mr. BRAITHWAITE said it was a farce to take the poll.

The CHAIRMAN stated that the result would be the same. He afterwards proposed the next resolution.

Mr. WAPSHARE having seconded the motion,

Mr. BRAITHWAITE said he was advised that if they accepted the shares of the Consolidated Company, as proposed, it would be useless for them to call in question any of the proceedings which led to the formation of that company, which, he said, was established without consulting the shareholders. It was very probable, if they had had a shareholders' nominee on the liquidation, he would have found circumstances in connection with the formation of the Consolidated Company which would have enabled him to withhold any balance due by them under the agreement with that company. He therefore moved an amendment to the effect that the liquidator should hold the shares of the Consolidated Company until the conclusion of the liquidation of the Company.

The CHAIRMAN said he should oppose the amendment, as no notice had been given.

Mr. BRAITHWAITE said that no opportunity had been given them to do so. His firm addressed a letter to the Chairman and Directors as to the appointment of Mr. Stewart, and though that letter was answered by Mr. Offor, they received no official reply on the part of the Directors until they came to that meeting.

In answer to Mr. STEWART,

The CHAIRMAN said there was still £1,800 outstanding of the amount they had undertaken to lend to the Consolidated Company. He would deline to put the amendment. He put the resolution, which was lost on the show of hands, a poll again being demanded. He afterwards put the third resolution, with the same result. The polls were taken subsequently, the resolutions being carried.

The South Eastern (Brush) Electric Light and Power Company (Limited).

An extraordinary general meeting of this Company was held on 11th inst. at the offices, 68A, Cowcross-street, E.C.

Mr. FRY (the chairman) presided, and said that in proposing the first resolution the Directors were simply doing what they had announced their intention to do, and what he believed the shareholders desired. They were aware that a committee of investigation was appointed, of which Mr. Stewart, Mr. Hewitt, and Mr. Rennie were members. Their report was not adopted, but at the same time the Directors pledged themselves that at the earliest possible moment that they thought desirable in the interests of the Company to terminate its existence they would do so. He was present to propose the first resolution: "That the Company be wound up voluntarily, and that Mr. William Henry Pannell, of 38, Basinghall-street, London, chartered accountant, be appointed liquidator for the purposes of such winding up." In asking Mr. Pannell to undertake the duties of liquidator the Directors desired to avoid any conflict between themselves as representing a very large number of shareholders and others, who also represented a considerable section of the shareholders. It was thought that if a Director were proposed, or two Directors, it might be open to objection, and as a certain section of the shareholders had put forward as their nominees two shareholders outside the Board, it was thought that the more dignified manner of disposing of the liquidation was to leave it to a man possessed of considerable experience and of high standing. He had therefore very great pleasure in recommending the resolution to their consideration.

Mr. WAPSHARE seconded the resolution.

Mr. J. B. BRAITHWAITE said that he and his firm, feeling that it was only right that some shareholder should be associated with Mr. Pannell in the liquidation of the Company, wrote to the Directors asking whether they would accept Mr. C. H. Stewart. To that communication they had received no official reply beyond a letter acknowledging its receipt, and he therefore now asked the Chairman whether the Directors were prepared to assent to the appointment of Mr. Stewart.

The CHAIRMAN: Certainly not.

Mr. BRAITHWAITE said that in that case he would move an amendment that the first resolution terminate at the word "voluntary."

The CHAIRMAN ruled, as in the previous meeting, that no amendment could be proposed.

Mr. BRAITHWAITE then moved the adjournment of the meeting.

The CHAIRMAN said that no good would be gained by adopting such a course, as at any adjournment only the business fixed for this meeting could be transacted, and again the present resolutions must either be accepted or rejected in their present form.

Mr. BRAITHWAITE thereupon withdrew his motion for adjournment, and after a long discussion of a personal nature the original motion was put to the meeting and lost on the show of hands.

A poll was demanded on behalf of the Directors, and it was at once proceeded with. The resolution was again lost on account of the requisite majority of three-fourths not having voted in its favour. The numbers were—For the resolution, 5,162 votes; against the resolution, 1,760 votes.

The CHAIRMAN said that the business of the Company would now have to be continued, and calls would have to be made.

In reply to a question, the CHAIRMAN said that he should decline to act as a liquidator with Mr. Pannell or Mr. Stewart, as he did not think that he had been properly treated by a certain section of the shareholders.

Mr. BRAITHWAITE said that it was his desire to see the Company liquidated as cheaply and as speedily as possible, and asked the Chairman if he would support a proposal, if it were made at another meeting, to appoint other liquidators than those suggested by the Directors.

The CHAIRMAN declined to give any promise, and repudiated any idea that Mr. Pannell was in any way the nominee of the Board.

After some further conversation the meeting broke up.

THE INTERNATIONAL INVENTIONS EXHIBITION.

DYNAMO-ELECTRIC MACHINERY.

BY W. M. MORDEY.

Probably for the general public, and certainly for the electrical world, the electric lighting apparatus will prove to be the most interesting and important of all the displays at the Inventions Exhibition. Whatever other solid educational results the Exhibition may have, it cannot fail in impressing on the public the fact that electric lighting has now so far emerged from the experimental stage as to have fully entered on its career as a practical commercial branch of engineering. And, before all things, it is perhaps necessary to the extensive application of electricity in the immediate future that the public should be satisfied on this point, in order that the feeling of scepticism or uncertainty which is one of the barriers to house-to-house lighting may be removed. Many reasons have been given for the slow progress hitherto made in this country in the application of the electric light, and no doubt the causes of this slowness are very numerous and varied; but perhaps it has not been sufficiently recognised that the public are not yet educated up to the point of a confident belief in the possibility of successful electric lighting on a large scale. The attitude of the man who would not go into the water until he had learnt to swim is very like that of the public with regard to this matter. Until a town, or a considerable portion of a town, has been lighted by electricity, it may be said that it will be very difficult to get a town lighted electrically. But here in the Exhibition may be seen electric lighting, approaching in amount that necessary for a town district, successfully carried out under conditions that are distinctly unfavourable from the suppliers' point of view. It may not be too much to hope that this Exhibition will at least do a great deal to remove any prevalent feelings of uncertainty, and that visitors may be not only pleased and dazzled by all that electricians have to show them in the grounds and in the Exhibition buildings themselves, but that their minds may be fully opened to the solid commercial possibilities of this new department of engineering.

The first feeling produced in the mind of an observant visitor to the Exhibition, who is acquainted with the general principles of apparatus for the generation of electricity, will be one of some disappointment at the absence of anything at all approaching to a startling novelty; but a little consideration ought to convince him that this absence of new things is really a most hopeful sign, showing, as it does, that the construction of electrical machines has settled down into certain grooves which have been proved by experience to be the best; and that therefore the element of permanency has been introduced into the manufacture. It is not that inventors and scientists have been idle during the past year or two, for readers of contemporary scientific literature well know that a very great number of earnest workers have been, and are, engaged in the investigation of all questions relating to the application of electricity, and that no point has received more careful attention than the dynamo machine. It may therefore be taken for granted that if inventors have little or nothing new in principle to bring forward it is because they are satisfied that known types of machines contain in them the elements of the greatest attainable perfection, and that progress is not so much to be sought in the direction of new forms as in the careful study of old ones, with a view to the elimination, as far as possible, of all prejudicial actions and causes of loss. Thus it is to be noted that while few, if any, of the dynamo machines at work or on exhibition contain anything essentially new scientifically, many of them show that great attention has been given to all such points as render them capable of working economically and satisfactorily for long periods. The machines are for the most part well and soundly constructed mechanically. They are much less likely to break down or get out of order than was the case a year or two ago, while attention has been given to practical details, such as facilitate examination and repair, and enable the operations of taking to pieces or putting together to be easily carried on. The opportunity afforded of observing the working, as well as studying the construction, of the Thomson-Houston apparatus will be welcomed by English electricians, who have only hitherto been made acquainted with this system through the medium of the technical press; the machines now shown being, we believe, the first that have reached this side of the Atlantic. It is an interesting, and, perhaps, a significant fact that almost all American electric lighting inventions consist of "systems" more or less fully developed and self contained. If we glance at the principal importation of this class from the United States—the inventions of Edison, Brush, Maxim-Weston, Hochhausen, and now of Thomson-Houston—we see not a separate dynamo in one, and a new lamp in another, but a full set of apparatus worked out in all or most of the details necessary for actual installation; and including dynamos, methods of current or electromotive force regulation, lamps, cut outs, meters, conductors, and fittings. This attempted completeness, which is at least as striking in this the latest arrival as in any of the others, well illustrates the inventiveness of our American cousins; and shows, also, their keen practical commercial instinct.

While engaged in noting the general impressions produced on the mind by what is to be seen at the Exhibition, it may not be out of place to say a few words about some things that are conspicuous by their absence—some inventions that might have been expected to be shown. There is no doubt that for some time there has been "in the air" a sort of ill-defined idea that there was nothing permanent about the present principles employed in the construction of dynamos, and that some great discovery might be expected that would completely revolutionise existing methods, and enable electricity to be generated with great ease and vastly increased economy. Such expectations as these are no doubt inseparable from the existing general state of popular knowledge of electrical principles. At the same time it must be confessed that it is not only among the general public that these ideas are met with—there are recorded opinions expressed by one or two well known men which have perhaps been taken too literally, and a public accustomed to startling revelations of science, and especially of electrical science, has seized on them in its blind belief that nothing is impossible to science.

We have said that the absence from the Exhibition of anything very new in principle, or new in the application of an old and known principle, was rather a healthy sign than otherwise, because it tends to allay all feeling of expectation of the sort we have mentioned. If we try and trace these ideas back to their source we shall find—where they have any distinct form at all—that we are led in one direction to "unipolar" induction, and in another direction to thermo-electricity. With regard to "unipolar" induction—to employ the unfortunate and misleading term, of Continental origin, by which the magneto-electric induction of continuous currents, without commutation is known—it may be said at once, we think, that although the principle holds out a promise of practical use for certain purposes where low potential and large quantity are required, it is very unlikely that for other purposes than these it will ever meet with extensive application. But even if it be supposed for the sake of argument that machines may at some future time be constructed on the principle of "unipolar" induction, capable of producing high electromotive forces suitable for general employment, it would be easy to arrive at the conclusion that no great advance in economy of electrical production could result, since existing forms of generators now succeed in returning, as electrical energy, so large a proportion of the mechanical energy expended in them that further advance in this direction is practically impossible. We are well within the mark when we say that any fair commercial dynamo will account electrically for 90 per cent. of the power delivered to it, and will give 80 per cent. as a useful commercial return. It must therefore be evident that, as far as economy in the generation

Digitized by Google

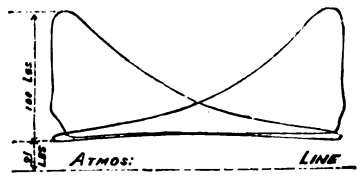
of electricity is concerned, when a steam engine or other source of motive power is relied on no further substantial improvement is possible in the electric generator. But no doubt the advocates of "unipolar" machines would say that, in the matter of the collection of the generated current, a machine without a commutator offers practical advantages over all ordinary commutating machines. This argument was freely advanced three or four years ago in support of alternate current dynamos, although in some of these machines the collection of the current does not appear to be very simple, being certainly not less troublesome than in many continuous current generators; while it is only necessary to examine the majority of the dynamos working in the shed, and elsewhere in the Exhibition, to be convinced that the difficulty of collecting even very large continuous currents has practically disappeared, little or nothing remaining for improvement in this direction, and that little being attainable by known means. Of course, in a "unipolar" dynamo the collection of any given current by some form of rubbing contact must always be less difficult than the collection of the same current from a commutated armature (assuming that the velocity at the contact is the same in the two cases), because in the latter, in addition to the electrical resistance and mechanical friction, there is a certain amount of difficulty produced by the act of commutation. But, seeing how small is the objection to ordinary dynamos on this ground, it is not likely, even if they could be made suitable in other ways, that in this matter of current collection "unipolar dynamos" can ever be expected to offer such great advantages as to lead to their extensive use. The trouble, such as it is, in these machines might be completely overcome by making use of stationary armatures and revolving field magnets, although it is probable that the great mass of the latter would stand in the way of such a solution of the question. So that on no sufficient ground is there reason to believe that any radical change in the principles of generating machines is in store for us.

But, while it is clear that no great improvement in this direction is to be looked for, it must not be forgotten that the dynamo is only one of the agents concerned in converting the heat energy of the coal into electrical energy, and that the great loss is in the steam generator and motor. The fact that so large a proportion of the energy of the fuel is lost has led to many attempts at various times to obtain electricity by the application of the principle discovered by Seebeck, that an electromotive force was produced by heating the contact junction of two dissimilar metals. And quite recently a fresh impetus has been given to the consideration of the subject, and a certain amount of rather wild anticipation has been indulged in by a portion of the public, as a result of some observations reported to have been made by Mr. Edison to some journalists by whom he was interviewed. From the newspaper paragraphs we learn that Mr. Edison is engaged in an attempt "to get electricity direct from the coal." This may reasonably be supposed to mean that he is trying to find a practical and satisfactory form of thermopile, capable of being used for the production of the large currents necessary in electric lighting and distribution of power. A great many attempts have been made in this direction; but never with any very good results. At the Health Exhibition last year a large thermopile was in course of construction in the dynamo shed, but it appears that it either was not completed, or was not found to act satisfactorily, as it was never exhibited; and no account of it, as far as we are aware, was published. The difficulties attending the construction of large thermopiles are apparently very great. The metals most suitable for the purpose are of high specific resistance, and the high temperature necessary to obtain good results, besides increasing the resistance, appears to render the maintenance of the junctions by no means an easy matter. The resistance can be reduced by increase of the cross section of the elements, but this is objectionable for several very good reasons. Until the elementary difficulties are overcome, it is almost unnecessary to inquire into the question of how far the problem of the economical employment of fuel can be solved by means of thermopiles; while it must be recognised that were the solution even as satisfactory as Mr. Edison could desire, it could not lead to results as regards efficiency surpassing the generation of electricity by dynamo machines driven by plentiful water power.

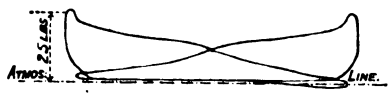
(To be continued.)

ENGINES.

Messrs. Robey and Co., of the Globe Works, Lincoln, exhibit two engines which they are desirous of introducing to the notice of electric light engineers. We are indebted to Messrs. Robey for the illustration of these machines. Fig. 1 shows one of their special semi-fixed compound engines, which they claim possess several advantages, and that they are most economical engines. In ordinary high-pressure engines the steam, after having done its work in propelling the piston to the end of its stroke, is discharged direct into the atmosphere, very often (especially in badly designed engines) at a considerable pressure, and, in consequence, a loss of power. For many years past attempts have been made to avoid the loss by passing the exhaust steam into a second cylinder of larger diameter, and then utilising its remaining energy, and as far



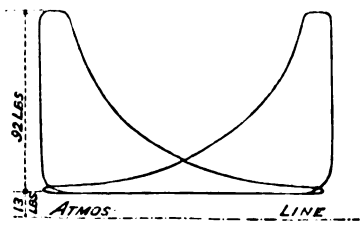
Scale 1/144.



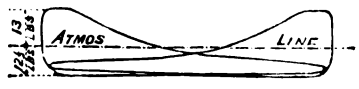
Scale 1/72.

Set C.—From an Engine 20 H.-P. nominal.

back as the year 1864 Robey and Co. constructed engines on this plan. Owing to improvements in their high pressure engines, the construction of compound engines was for a time discontinued. Of late, however, Robey and Co. have made such further improvements in the construction of compound



Scale 1/96.



Scale 1/72.

Set D.--From an Engine 40 H.-P. nominal.

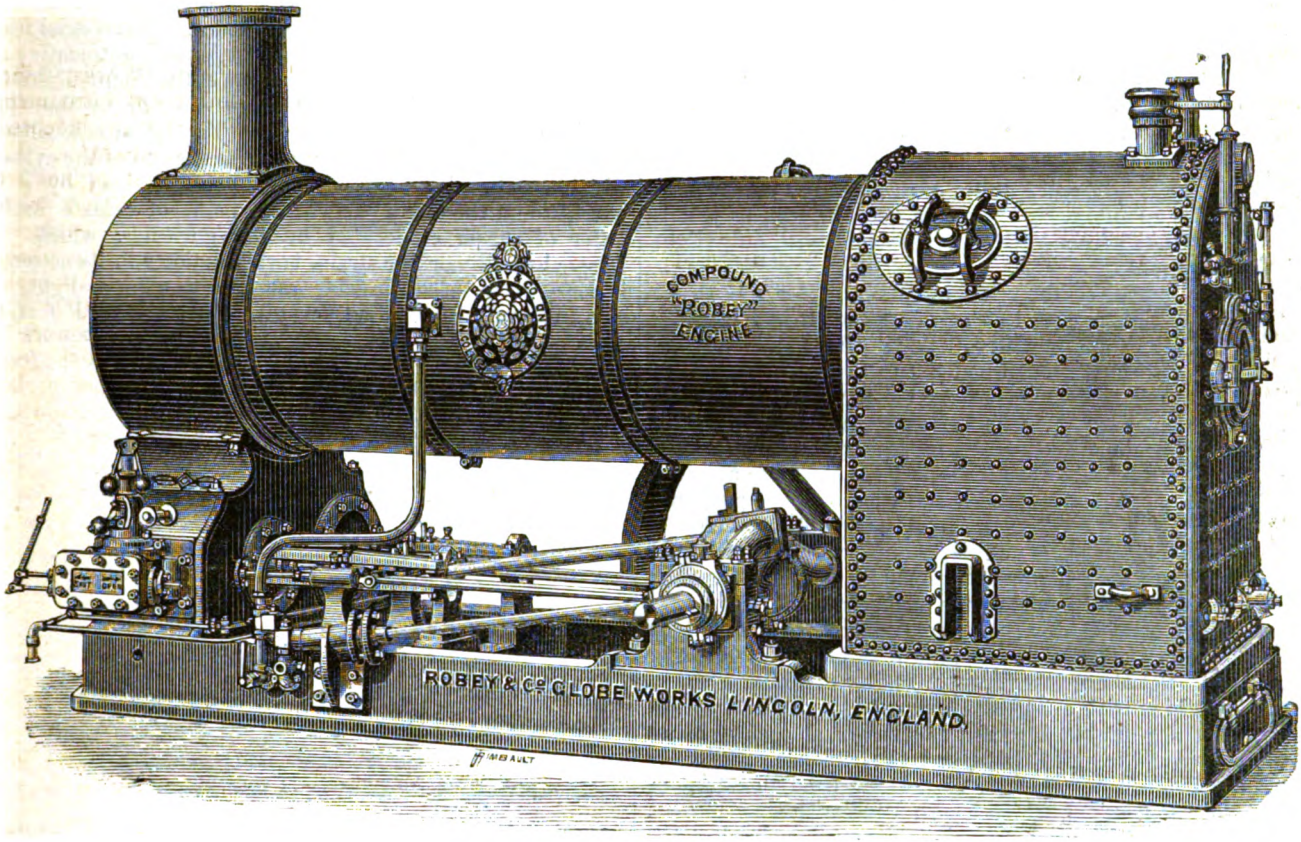
engines as to secure an economy of fuel rarely equalled in even the best class of condensing marine engines. Commencing with steam of at least 120lb. pressure, this is expanded in the two cylinders down to atmosphere pressure, being reheated on its way in an intermediate receiver of large capacity, thus avoiding the great loss between the two cylinders so often found in engines of the compound type.

Another point of great importance is the proper distribution of the steam between the high and low pressure cylinders, this being often so incorrectly done that the one cylinder acts as a brake upon the other, and a loss instead of saving is the

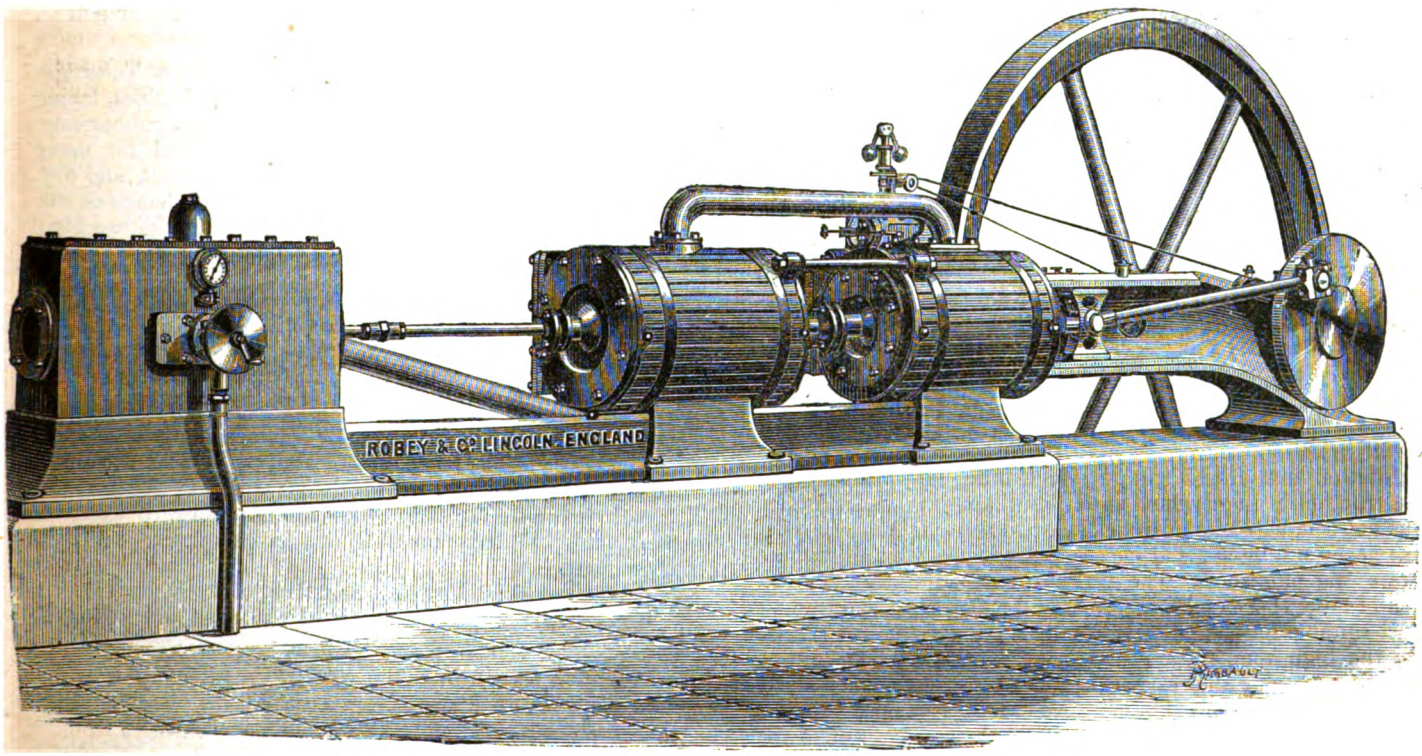
Digitized by Google

result. The valve gear in the Robey engine is arranged so that this loss can never take place. The working parts are arranged to be easily accessible for examination and adjustment, and the whole construction has been made so strong and simple that

the best point for an average load. The larger engines (*i.e.*, 25 horse-power and upwards) have independent cut-off valves, worked by separate excentrics, so that the ratio of expansion may be varied if required. The cylinders are steam-jacketed,



Robey's Semi-Fixed Compound Engine.



Robey's Fixed Compound Engine.

it can be worked with the same ease as any ordinary double cylinder engine. The smaller engines are arranged to work with one slide valve to each cylinder, with its cut-off fixed at

made of good hard metal, free from blowholes and other imperfections, and each is fitted with a metal lever made of specially hard, close-grained metal. The cylinders are provided

Digitized by Google

with drain cocks to the end of each cylinder, as well as to the steam jacket, and additional cocks for taking off indicator diagrams. The main valve to high pressure cylinder is made of best gun metal.

The piston and valve rods are of steel, the valve rod joints have case-hardened pins, and the large sizes have adjustable cotters for taking up the wear. The stuffing boxes are all fitted with gun metal glands.

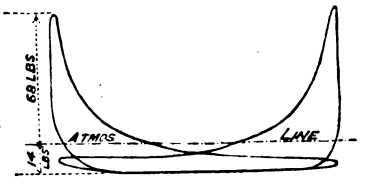
The crank shaft is of steel, forged solid, and the web slotted out, and each crank is supplied with balance weights, so as to accurately counterpoise the moving parts. The engine is fitted, when required, with a delicately-adjusted governor, controlling the cut-off valve of the high-pressure cylinder, the whole forming an automatic expansion gear, by which the cut-off can be regulated from $\frac{1}{8}$ to $\frac{5}{8}$ of the stroke with only slight variations in speed.

The main bearings are of gun metal and are adjustable in three directions. Lubricators are fitted to all working parts, specially constructed for long runs and suitable for electric lighting. The boiler tubes are arranged in vertical lines and with wide spaces to prevent the formation of scale upon them. The boilers are double riveted in all seams, and are made to stand a working pressure of 140lb. The corners of the firebox are made of large radius to admit of the mud hole plugs in the corners, and the mud hole plugs are so distributed that a scraper can be passed between each row of stays in a firebox shell. A series of carefully conducted tests shows that these improved compound engines will work with a consumption of less than 2lb. of Welsh coal per horse-power per hour when developing two and a half times their nominal power. The accompanying diagrams will explain themselves. Set C are taken from an engine of 20 horse-power nominal, working with a load of 54 horse-power indicated; the steam, entering the high-pressure cylinder at nearly boiler pressure, is expanded nine times, and the exhaust pressure is reduced to atmosphere pressure. Set D are from an engine of 40 horse-power nominal, which is also fitted with a condenser; the small consumption of fuel in this engine enables the exhaust draught in the chimney to be dispensed with.

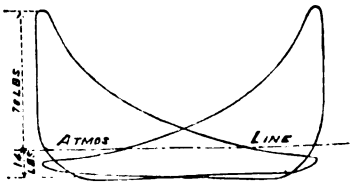
The speed arrangement, instead of being done in the ordinary manner by a speed governor driven by the engine, is controlled entirely by electricity, this giving it a special advantage in driving electric light installations. A portion of the current generated by the machine is used to excite the coils of the solenoid, which holds suspended within it an iron core, to one end of which is attached the end of the long arm of a lever, the short arm of which works upon a double beat Cornish valve, which regulates the admission of steam. The governor is arranged to maintain a constant current, or constant E.M.F., as may be required, and is so sensitive that the slightest change as it works is felt and responded to by the engineer.

When driving incandescent lamps with an ordinary shunt-wound machine, the lights may be varied to any extent within the limits of the power of the machine, without the slightest risk of injury to the lamps, the power developed by the engine and the speed of the machine depending entirely upon the amount of work done by it. In arc lighting this is very important, the speed of the machine being reduced within certain limits in almost exact ratio with the number of lamps turned out. It is well known that there is a special pressure of steam and point of cut-off which gives the best result in compound engines, and an engine which when developing, say, 20 horse-power may be a very economical motor, becomes extremely wasteful if called upon to develop 10 horse-power at the same speed, the steam being cut off at so early a point as to become expanded far below the atmosphere, thus converting the low pressure cylinder into a brake, whereas if this speed could be reduced to 10 revolutions the pressure and cut-off would remain constant, and every stroke of the engine would be delivered with the same economy as at the higher speed, while the wear and tear would of course only be one-fifth. This is exactly what is accomplished by the use of the electric regulator, and the greatest success has been attained by this apparatus in regular use.

Fig. 2 shows an improved horizontal fixed engine, with "Proell" automatic expansion gear, intended for large permanent installations. In such work it is important that great strength and solidity should be secured, and that regularity in running should be obtained. These important points are claimed for the engine here illustrated. It will be seen from the illustration that from the shape of the guides the engine is rigid in all directions, and has a most substantial base, both under the main bearing and the cylinder. The special feature of this engine is the arrangement of Dr. Proell's automatic expansion gear, which gave such good results at the Vienna Exhibition. The results obtained for this gear are superior to the Corliss gear, while the apparatus is simple. The steam is admitted by two Cornish equilibrium valves (one at the end of the cylinder), which are lifted so as to give a constant lead by a fixed excentric on the crank shaft. The point of release and the order of cut-off is decided by the governor, which, being relieved of all work or strain, is very delicate in its action, and is constructed to have a wide range with a very slight variation in speed. In the diagrams given below, Figs. F 1 and F 2



Scale 1/96.



Scale 1/96.

Figs. F 1 and F 2.—From an Engine 50 H.-P. nominal.

are taken from an engine of 50 h.-p. nominal, and range from 25 to 200 h.-p., the variations in speed being not more than one revolution of the engine. It will be seen that even with the very earliest cut-off, as little as 1-30th, the admission of steam is full and the cut-off as perfect as with a later point.

EAST ARCADE.

An exhibit to be noted is that of Henley's Telegraph Company, who show specimens of their make of cables, laying stress upon the value of their ozokerited india rubber core. Of this core we are told that "it has been boiled for many hours, it has been frozen, and made alternately wet and dry, hot and cold, without undergoing the slightest change or sustaining the least loss of insulation." There is also shown Henley's patent cast and wrought-iron troughing for underground conductors.

Close by, Callender's Bitumen Telegraph Company have an exhibit of their make of cables. There is nothing new to chronicle in the manufacture of these cables, but we may say that they have a fairly extensive and satisfactory use. We are inclined to think that in the near future the users of electric light leads will specify their wants, somewhat after the manner of the cable companies. They will have wire of a certain conductivity, and the insulation will also be specified. The various companies who exhibit are used to such specifications, and will have no difficulty in complying with the requirements.

Messrs. Thompson, Dowsing, and Rew, of 4, Queen Victoria-street, E.C., have a large number of excellent and well-made appliances on view, amongst which we noticed the following:—Dynamos, ammeters, and voltmeters, &c.; the Howell patent accumulator, with plates cut from a porous preparation of lead; Alexandra incandescent lamps, of a new shape; the Carré improved carbons, for arc lamps, batteries, telephones, &c.; terminals of all kinds, and a number of admirable specimens of their patent connected and single link chain leather belting, made with both oak and orange tanned leather. The latter is too well known to need description. Suffice it to say that it is perfectly adapted for the requirements of electric lighting.

NOTES.

THE SPANISH TELEGRAPHS.—Telegraphic communication with Madrid has been delayed by heavy rains.

THE INSTALLATION AT WHITELEY'S.—This installation, which had but recently been put down, cost about £2,000.

EASTERN TELEGRAPH COMPANY. — The annual general meeting of this company will take place on the 16th prox.

POSTAL APPOINTMENT.—Mr. W. H. Callway, telegraph superintendent at Newport, Monmouth, has been appointed postmaster of Swindon.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 12th inst. amounted to £3,027.

THE HAMMOND COMPANY.—From the report in another column it will be seen that the shareholders have resolved upon winding up this company.

THE GREAT NORTHERN TELEGRAPH COMPANY.—A half-yearly interim dividend, at the rate of 5 per cent. per annum, is notified on the shares of this company.

THE DYNAMICABLES.—Instead of their usual meeting this month the Dynamicables have arranged for a visit to-day to Messrs. R. E. Crompton's works at Chelmsford.

LONG DISTANCE TELEPHONY.—A long distance system of telephony by the existent telegraph wires was opened for service on the 1st inst. between Bruxelles and Liège.

APPOINTMENT.—M. Felix Neumann has been appointed Director of the Administration of Posts and Telegraphs of the Grand Duchy of Luxembourg, in place of M. Charles Rischard.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 12th inst., were £2,418, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE SOCIETY OF TELEGRAPH-ENGINEERS.—Invitations have been issued by the president of the above society to visit, by permission of the chairman and directors of the Great Western Railway Company, their engineering works at Swindon on Tuesday, the 30th inst.

THE MILLER PRIZE.—We have great pleasure in announcing that the "Miller Prize" of £20 has been awarded by the Council of the Institution of Civil Engineers to Mr. F. Geere Howard for his very able paper on "Secondary Batteries," read on 16th January at a students' meeting.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th inst. are £2,984, as compared with £3,066 in the corresponding period of 1884. The February receipts, estimated at £4,722, realised £4,854.

A NEW LIGHTNING GUARD.—The general manager of the Pueblo Telephone Company of Mexico has invented a lightning guard for the use of telephone and telegraph companies, which is said to have proved by actual test to be of great importance. Patents have been applied for in Mexico and the United States.

LIGHTING OF DOCK HOUSE.—Messrs. R. E. Crompton and Co. have received instructions from the East and West India Dock Company to light up their London premises, known as "Dock House," Billiter-street. The installation will include a 3½ h.-p. "Otto" gas engine, a Crompton dynamo, and a number of Dr. Frankland's accumulators.

LUXURIOUS VOLUNTEERS.—During the volunteer review at Dunedin, New Zealand, the camp was lit in the evening by the electric light, which was lent by the Harbour Board, and the evening was given up to amusement. The various bands in camp played during the evening, and dancing, kiss in the ring, and other games were kept up with spirit for a couple of hours.

THE TELEGRAPH IN FRANCE.—By order of the Minister of Posts and Telegraphs, the creation of municipal telegraph offices has been authorised in the following communes:—Quintenas (Ardéche), Brusque, Fayet (Aveyron); Chélan (Gers), Saint-Aubin (Gironde), Meylan (Isère), Chaumont-sous-Tharenne (Loir-et-Cher), Molitg (Pyrénées-Orientales), Julienas, Julii (Rhône).

THE ANTWERP EXHIBITION.—The Belgian Government having requested Earl Granville to make appointments of British jurors, his lordship has communicated the following names, among others, to Baron Solvyns, the Belgian Minister:—Section IV. Electricity: Captain Abney, R.E., F.R.S.; Mr. W. H. Preece, F.R.S., assistant engineer and electrician to the Post Office.

EARTHQUAKES IN CASHMERE.—A Reuter's telegram, dated Simla, June 13, says:—Shocks of earthquake continue to be felt in Cashmere at the rate of from eight to ten daily, but their violence is abating. Advices, however, dated the 16th inst., state that the shocks have again occurred with increased violence. It is reported that 2,281 persons have perished in the district of Muzurfurabad.

THE ELECTRIC LIGHT IN ITALY.—The installation for the railway station of San Pierdarena is nearly completed. The dynamos will be driven by two turbines; the nine arc lamps are of 6,000 candle-power each, and the total cost is estimated at £4,000. The little town of Aosta has recently been successfully lighted by Cruto incandescent lamps. The current is supplied by a Thury dynamo.

BREAKING TELEGRAPH INSULATORS.—At the Birmingham Police-court three youths have been fined 5s. each and costs for breaking telegraph insulators. The inspector of the local telegraph department said that no fewer than 2,000 insulators had been broken along the telegraph wire by the side of the Birmingham Canal since January last. Each insulator cost 1s., without reckoning the expence of fixing.

SIXPENNY TELEGRAMS.—The prospects of the Sixpenny Telegrams Bill have not been improved by the advent of a Conservative Government; and in any case there is no likelihood of the scheme coming into operation before the autumn. The Press Association states that Lord John Manners is to be the new Postmaster-General; but we have reason to believe that this appointment had not been filled down to the time of our going to press.

THE ELECTRIC LIGHT AND THE EVOLUTIONARY SQUADRON.—The operations in connection with the visit of the Evolutionary Squadron to Bantry Bay are proceeding with remarkable briskness. A double row of spars tightly lashed together has been spread across the mouth of the bay, and an attempt will be made by the gunboats, which are of about 250 tons displacement, to ride or jump these barriers. The experiment will take place in the night time, and will be lighted by the electric light.

ACCUMULATORS AND INDUCTION COILS.—At the Royal College of Science, Dublin, electrical accumulators are employed in connection with inductoria, for which they are obviously well adapted on account of the very even flow of

Digitized by Google

current which they give and of their ability of producing very powerful currents, and more particularly on account of the very slight attendance which they necessitate. Frankland accumulators are employed, which were supplied by Messrs. A. R. Sennett and Co.

THE ELECTRIC LIGHT IN VIENNA.—We understand that Mr. R. E. Crompton has been in Vienna for the last fortnight, making arrangements for carrying out a large installation which he has in hand for the Imperial and Continental Gas Association. We believe Mr. Crompton will have not only the electrical work to carry out, but the engines and boilers will also be placed in his hands. This installation will be one of the largest of its kind, and it is thought the forerunner of many more in other important cities.

THE TELEPHONE AND FIRES.—On the occasion of the recent fire at Whiteley's establishment in Westbourne-grove, the electric street call which the Paddington firemen received was immediately transmitted to the superintendent of the district, Mr. Palmer, at the district depôt in Westminster, and was forwarded thence by telephone to Winchester House, Southwark Bridge-road. Thus three of the chief authorities of the brigade were made acquainted with the serious character of the outbreak in a space of time to be measured by seconds.

THE ELECTRIC LIGHT IN LOWESTOFT.—The electric light will shortly make its first appearance in Lowestoft, Messrs. A. R. Sennett and Co. having received instructions to light up the house of Mr. Youngman. The house will be lighted by means of Frankland accumulators, and the motive power will be derived during the daytime from an engine situated in a brewery at some distance from the house. There is a great opening for electricity in the lighting of residences of owners of mills, factories, &c., situated a short distance from them.

THE COMMERCIAL COMPANY'S CABLES.—The work of duplexing these cables on the Muirhead system is almost completed. The main cables were in the first instance duplexed, the Waterville-Havre section has just been completed, and the Canso-Nova Scotia-New York section is in hand. Altogether the total length of cable duplexed is about 6,800 miles. It might be here stated that the Waterville-Bristol section, consisting of a two-cored cable, has been laid. This work has been carried out under the direct supervision of Dr. Muirhead and Mr. John Muirhead.

TELEGRAPH CABLE FOR THE MORAY FIRTH.—Her Majesty's telegraph ship "Monarch" anchored off Burghead on the 3rd inst., and landed Mr. Cunningham, Mr. Lumsden, &c., of the General Post Office, who inspected the locality for a suitable site for landing the shore end of a cable, which is to be laid across the Moray Firth, and which is necessitated by the extension of the telegraph system to the Shetlands and by the introduction of the sixpenny telegrams. The steamer subsequently left for Helmsdale, where the northern end of the cable is to be connected with the existing telegraph system.

ELECTRICITY IN ASYLUMS FOR THE INSANE.—Messrs. Harrison, Cox-Walker and Co., of Darlington, have contracted to supply the Holloway Sanatorium, which was opened by the Prince and Princess of Wales on Monday last, with an electric tell-tale apparatus similar to that supplied by the same firm to the County Asylum of Worcester. The apparatus will record on a sheet, in the head physician's room, every visit made during the night, at thirty different stations, by the warders of the establishment. Electric fire-alarm apparatus and electric bells are being furnished throughout by the same firm.

THE SS. "GREAT NORTHERN."—The repairing ship of the Eastern and South African Telegraph Company, the "Great Northern," has returned home after a stay of nearly five years on the east coast of Africa. During that time she has, under the able direction of Captain Richardson, and Mr. W. H. Cotterell, the chief electrician, done some very excellent work in connection with the company's cables. We are happy to be able to congratulate Captain Richardson and Mr. Cotterell upon the successful termination of their labours. Holiday-making will, in all probability, occupy their attention for some time to come, and we doubt not that the interval will be enjoyed as much as it is deserved.

CONDUIT FOR UNDERGROUND WIRES.—The Washington *Star* gives the following description of the conduit for the Western Union Telegraph Company's wires which are now being put underground in Washington: "The conduit is made of cypress logs, hollowed out like pump logs. They are laid two abreast, making a double conduit. At spaces of about 450ft. boxes are put in, covered with oblong iron covers at the surface, so that any portion of the cable or conduit can be taken up or examined if the necessity arises. The conduit to be laid through the President's grounds will be of the same character. The logs, or pipes, which have a bore about four inches in diameter, are laid about two feet below the surface of the ground or sidewalk."

THE ELECTRIC LIGHT IN PARIS.—It has been decided to light the Eldorado Café, Boulevard de Strasbourg, by electricity. The lighting will be carried out by 25 to 30 Cance arc lamps and from 35 to 70 Edison incandescents. An Olry and Granddemange engine of 40 horse-power, alimented by a Collet inexplosible boiler, will drive the dynamos, which are of the Gramme type, constructed by the firm of Ducommun, of Mulhouse. The work is to be finished and in order by the middle of next month. The management of the café have a very wise regard for the comfort of their clients during the hot summer months.—The Casino de Bougival was lighted last week by 16 Jablochkoff lamps; and 20 lamps of the same system are installed at the Jardin de Paris in the Champs Elysées. These installations have been put down by the Société l'Eclairage Electrique, who have employed the new Bobenrieth chandeliers to carry the lights.

THE VAN RYSSELBERGHE SYSTEM.—Our contemporary, *L'Etoile Belge*, in a recent issue again refers to the disputed adoption of the Van Rysselberghe system of simultaneous telephony and telegraphy by the French Minister of Posts and Telegraphs. According to our contemporary, M. Sarrien has not only confirmed the initiatory arrangements entered into by his eminent predecessor, M. Cochery, but has contracted with the agents of M. Van Rysselberghe for the sole right of working the patents upon the various telegraphic lines of the Republic. The first line to be so appropriated will be that between Paris and Rheims, followed by another from Paris to Rouen, and finally by a network of lines of greater or lesser importance. M. Sarrien is anxious to extend the use of the telephone to international communication. He proposes to connect Paris with Brussels, Antwerp, &c., and rumour, indeed, saith that projects still more ambitious are not undreamt of.

ELECTRIC LIGHT TESTS.—A further note on this subject says:—The electric light life test which has been going on at the Franklin Institute, Philadelphia, has reached its 1,064th hour. The Edison, the Weston, the Stanley, and the Woodhouse and Rawson Companies competed. The Sawyer-Mann and Brush-Swan Companies were invited, but declined to participate in the trial. Extraordinary precautions were taken

Digitized by Google

to prevent access to the lamps except by members of the committee. The lamps were lighted on 11th April, and have burned ever since. When these tests were taken the Edison Company, who had entered 21 lamps, had lost 1; the United States Company, who entered 24, had lost 17; the Stanley Company had lost 19 out of 22, and Woodhouse and Rawson, an English firm, had lost 11, or their whole number entered. The Edison Company used the natural fibre bamboo carbon, while the Weston people used the artificial tamidene carbon.

THE SOUTH AUSTRALIAN TELEGRAPHS.—The reduction in the cost of telegrams between Victoria and New South Wales, viz., a shilling for ten words, has been followed by satisfactory results. During the quarter ending March 31 last year the number of messages transmitted to New South Wales from Victoria was 29,851, and under the reduced rates for the corresponding quarter this year, 39,255, or 31½ per cent. increase; the revenue for the former period was £4,234, and for the latter £4,017, or a reduction of 5 per cent. An expense of nearly £7,000 had been incurred in the construction of a new line from Melbourne to Wodonga, and extra operators had cost £800 per year. Some time ago the authorities in Queensland and New Zealand were asked to agree to a proportionate reduction upon brief telegrams between those colonies and Victoria. The Queensland Government had, however, declined, preferring to see the outcome of the arrangements with Victoria and New South Wales.

THE INTENSITY OF SUN RAYS.—M. Morize, of Rio de Janeiro, has invented an ingenious selenium apparatus for measuring the relative intensities of the rays of the sun at different altitudes above the horizon. It consists of a selenium cylinder prepared according to the plan of Professor Graham Bell, 38 discs of copper being insulated from each other by smaller mica discs, and the edges filled in with selenium. It is insulated by glass supports inside a glass envelope, from which the air has been exhausted. The vessel is elevated in a place where surface reflection does not reach it, and the axis is placed parallel to the axis of the earth, so that the rays of the sun fall normally on the selenium cell, and illuminate the same surface. Its position can be altered to keep up this condition from day to day. A constant current traverses the selenium and a galvanometer in circuit with it. From darkness to the most intense radiation of the sun is the range to be observed, and a scale is graduated accordingly.

LIGHTNING RODS FOR HUMAN BEINGS.—Mr. P. B. Delany, of New York, inventor of the synchronous telegraph system, has, says the *Scientific American*, recently patented a lightning rod for the human body. It consists of a large copper wire that passes down the back, with branches extending along the arms to the hands, and along the legs to the exterior of the shoes and to metal soles thereon. The wearer if provided with this rod may, if standing on the ground, handle electric light wires with impunity; and if out in a thunderstorm would stand a good chance of not being hurt if his rod were struck by lightning. Mr. Delany ought to carry a branch of his rod up the back of the neck, and have it connect with a point on the helmet of the policemen, and so give them protection. It has heretofore been proposed to have lightning rod umbrellas, that is to say, an umbrella provided with a flexible wire that extends from the tip or ferrule over the outside of the umbrella, the wire reaching to and allowed to trail on the ground.

TELEPHONIC CHARGES IN LIVERPOOL.—A correspondent of the Liverpool *Daily Post* writes as follows:—"I am glad to see a movement is being made in the direction of a reduction of the telephonic charges, as it is high time a reduction of at least 50 per cent. was made on the present rates. It is this heavy charge that has debarred hundreds of would-be subscribers from joining and giving to it a fuller and wider scope. We who have been subscribers from the first have a right to complain of this. I cannot conceive on what basis the charges are arrived at by the company. Here, with all subscribers centralised, the charges are £20 per annum; in Oldham, under the same company, with few subscribers spread all over the town, the charge is £12 per annum, with benefit of free use of wire to Manchester. Unless some move is made by the subscribers, the company, no doubt, will be content to rest satisfied with present rates, rendering the same indifferent service. I for one (representing two subscriptions) am not content, and shall withdraw at the year end if an alteration be not made."

ELECTRIC LIGHTING OF TRAINS.—The German Railway Administration are making a series of experiments at Frankfort-on-Main, having for their object the determination of an economical and efficient method of railway carriage lighting. The incandescent lamp, it is needless to say, has been chosen for the purpose. The dynamo was connected up to the wheels of the carriages, and made about 700 revolutions per minute. As soon as the speed of the train exceeded 29 kilometres (17·98 miles) per hour, the dynamo generated sufficient energy to light the incandescent lamps, and charge a battery of accumulators placed in the luggage van. When the speed fell below that limit the dynamo was automatically switched out of circuit, and the current supplied by the battery. The cost of the dynamo and accumulators is said to have been £125, that of the installation for each carriage about £4. The price per lamp hour did not exceed one penny. The experiments were productive of great satisfaction, and we may reasonably hope to see the Administration taking, before very long, active steps to carry out the reform.

THE VOLCANIC ERUPTION IN JAVA.—Letters received from Sourabaya, in Java, contain particulars of the volcanic eruption that has taken place in that country, resulting, it is feared, in great loss of life and destruction of property. Smeroe, which is the principal volcano in East Java, had been showing signs of unusual activity, and early in May a terrible outburst of ashes and lava took place from the crater, which destroyed everything for miles round. Ravines 200 to 300ft. in depth were completely filled up by the streams of lava, and the face of the mountain, which until then was serried and dented by many a chain and glen, is now almost smooth. The coffee estate of Kalieda Bening was destroyed. It is estimated that 500 natives perished, as well as the manager of the estate and his two assistants. In mid-Java the appearance of the Merapi—also a volcano—was giving cause for much anxiety, and a disastrous eruption was dreaded. Volcanic rumblings had been heard from Krakataw Island, off the west coast of Java, accompanied by electric phenomena in the vicinity of the old crater, which nearly two years ago caused so much destruction. It was feared that another eruption was probably not far distant.

SUNDRY INSTALLATIONS.—The Gülcher Electric Light Company have recently extended their installation on the Benares Bridge over the Ganges. This bridge is in course of erection by the Oude and Rohilkund Railway Company, and the work is now carried on at night by means of 16 arc lights and 20 incandescent lamps driven from a No. 4 Gülcher dynamo. The above company have also recently completed the lighting of the grounds of the Crystal Palace, Sydenham, with 14 arc lights of 2,000 candle-power placed on high poles. It is intended to use this installation on *fête* nights, when the

Digitized by Google

grounds will be illuminated by the electric lamps and some thousands of oil lamps in coloured globes. The effect on the first night was everything that could be desired. The installation is driven from a No. 5 Gülcher dynamo, the motive power being obtained from a Robey double cylinder portable engine. This company is also extending its business through their New Zealand agents in that colony, and have recently supplied four of their No. 4 dynamos, each machine being capable of running 18 arc lights of 2,000 candle-power each. Messrs. Morewood and Co., Birmingham, have also placed an order for an extension to their already large electric lighting plant. This company has also orders on hand for several large plating dynamos.

ELECTRIC LIGHTING OF A BALL ROOM.—On the 11th inst. Messrs. A. R. Sennett and Co., of Hatton-garden, temporarily installed the electric light at Devonshire-street, Portland-place, on the occasion of a ball given by Mrs. Alexander. The ball room, boudoir, promenade, &c., were very extensive, and on account of the very elaborate way in which they were furnished, the electric light was shown to great advantage. About 150 lamps of various candle-power were employed for the lighting of the ball room, boudoirs, staircase, &c., about 100 of which were placed in the ball room. No fittings of any kind were employed, and a very handsome effect was produced by attaching a number of eight candle-power lamps to the blue brocaded silk curtains and valances of the apartment. In the other parts of the house they were supported on the tree ferns and other suitable positions. The light was very successful and gave great satisfaction. A portable engine, dynamo, and Frankland accumulators were employed, the whole arrangement being carried out by Messrs. Sennett in a little more than two days. We feel that these temporary installations when well carried out cannot fail to be of great service in permanently introducing the electric light, as it is brought under the notice of a great number of persons in one night and frequently leads to permanent installations.

VOLUNTEER TORPEDO SERVICE.—Dr. Fleming writes to the *Pall Mall Gazette* as follows :—"Your notice of the steps being taken to form a volunteer torpedo service for the protection of coast towns is one which should attract considerable attention. The recent developments of practical electricity and electrotechnology have created a large body of men all over the country who are more or less intimate with the apparatus of electricity and with mechanism, and who would, therefore, form a ready material out of which to construct a corps easy to train in matters relating to the use of mechanism. The applications of electricity in war and naval operations are yearly increasing, and it needs but a serious effort to be made to attract into such volunteer service numbers of those to whom things electrical are matters of daily experience. If you would lend to this object a fraction of that powerful assistance you have given and are giving to the question of national defences in general, it is highly probable that something useful would result, and that a volunteer torpedo service might arise composed of men instructed in the application of electricity to naval and military purposes, and who would understand not only torpedo work, but have ability to handle electric lighting for search lights, as well as field telegraphy and telephony, and whose aid in coast defence could not fail in time to become important."

VITIATED ATMOSPHERE. — A contemporary, avowedly devoted to the interests of gas lighting, says :—"According to one of the best authorities on ventilation 300 cubic feet of air per hour are required for every adult person in ordinary living rooms. Peclet says 250 cubic feet are sufficient. Less than this renders the atmosphere stuffy and unhealthy. It is generally admitted that an average adult breathes out from twenty to thirty cubic inches of steam and vitiated air per minute; or, as Dr. Arnott says, a quantity equal in bulk to that of a full sized orange. This vitiated air and steam is respired at a temperature of 90° Fahr., and therefore, by reason of this heat, it immediately ascends to the ceiling, together with the heat and carbonic acid given off from the pores of the skin. This fact, by-the-bye, can be clearly demonstrated by placing a person in the direct rays from a powerful electric lamp, and thus projecting his shadow sharply on a smooth white surface. It will be observed that from every hair of the head and beard, and every fibre of his clothing, a current of heated air in rapid movement is passing upwards towards the ceiling. These currents appear as white lines on the surface of the wall; the cause probably being that the extreme rarefaction of the air by the heat of the body enables the rays of light to pass through them with less refraction than through the denser and more moist surrounding cold air."

THE BIDWELL ELECTRIC RAILWAY.—"The electric railway soon to be constructed along Belmont-avenue, Philadelphia, will," says an American contemporary, "present the novel sight of cars running without any apparent propelling force, free from annoyance of noise, smoke, and dust. The motive power for the cars, which are to be run according to the Bidwell system, will be furnished from a station located somewhere on Belmont-avenue, outside the park. It could, if necessary, be carried *over an indefinite distance.* This system differs from other systems of electric railways in not passing the current through the rails. Guards made of lumber run along the inner side of the rails, and a broad covering projects towards the centre, leaving a narrow slot in the middle of the track. Beneath this cover, and parallel with the rails, properly insulated copper conductors of a semi-tubular shape, are placed. The current is conveyed from the dynamos supplying the power through wires to the terminus of the railway, where connection is made with the copper tubes, and a current is thus sent through the whole length of the road. To propel the car a receiving dynamo or electro-motor is placed in the centre of the car. Connection with the current is made by means of an iron tube passing down through the slot, with branches in either direction in the form of an inverted T. On the end of each branch a small wheel, so placed as to run against the copper conductors, completes the connection, wires being run through the tube from the electro-motor in the car to the wheels. The electricity being passed through the circuit of the track, the operator has but to turn a lever to receive the current in the motor, which immediately revolves, and by an attachment with the wheels of the car propels it in either direction, according as the current is reversed or not. Through the reversal of currents the need of brakes is dispensed with. If necessary, the car can be brought to a sudden stand-still, but the change can be effected as gradually as may be desired. There will, therefore, be no danger of running over persons on the track. The avenue will be lighted with the same current by running wires from the tubes to the lamps, as in ordinary street lighting, while the cars will be illuminated by running a wire from the motor to the incandescent lamps in the interior of the car, *the whole power coming from the single current supplied by the stationary engines* some distance away from the track. If it is desired to heat the cars, another draft is made on the current by passing the electricity through some *poorly conducting substance, as German silver, the electrical energy being thereby dissipated in the form of heat.* These connections are made by means of switches, so that no current need be sent through the branch wires when

Digitized by Google

the light or heat is not wanted. An important feature of this railway for the park is the *utter impossibility of trifling with the conductors* and receiving injury from a shock. They are placed beneath the board flooring near the rails, and the only opening is the narrow slot, more than a foot distant, the whole being concealed from view. The road will be about a mile and a quarter long, and ten cars, carrying from fifty to sixty passengers, will be run. To furnish the power for these and to light both the avenue and the cars about 100 horse-power will be required." The italics are our own. Comment is needless. We should, however, like a little explanation as to the precise meaning of trifling with the conductors. We remember an individual attempting to trifle with an omnibus conductor and receiving decided injury from the shock; but perhaps we mistake our contemporary's meaning.

ELECTRICITY AND THE GAS INSTITUTE.—The twenty-second annual general meeting of the members of the Gas Institute was held at the Memorial Hall, Manchester, on the 9th, 10th, and 11th inst. The chair was occupied by the President, Mr. Thomas Newbigging, who, in the course of his address, said :—"It has been the custom of late of certain writers and speakers to say that the recent advent of the electric light has had the effect of infusing new life into the action of the gas authorities of the kingdom. The truth of that assertion I dispute. Undoubtedly the introduction of the electric light in its recent development has led to a demand on the part of the public for more light in the streets and other thoroughfares of our cities and towns. The cry has awakened the authorities of such towns and cities who control the public lighting, from the lethargic state into which they had sunk, and gas engineers, as they were always ready to do, have responded to the demand, and are still prepared to go as far in that direction as the public desire. Whilst on this subject I may be allowed to express the opinion that competition by the electric light in England under existing circumstances is out of the question. Even in countries where gas is sold at 20s. per 1,000 cubic feet, electricity stands but little chance with gas as an illuminant; and how, then, can it possibly compete with gas at, say, 2s. 6d. or 3s. per 1,000? The suggestion may be dismissed as absurd. We are, of course, aware that there are other considerations besides that of mere cost. One of the recommendations of the electric light is that it gives out little or no heat. By one person in a thousand this may be deemed an advantage; but I have yet to learn that the grateful warmth of the gas-flame is objectionable. Stuffy, ill-ventilated rooms are an evil; but it is one for which the architect is to blame, and which the heat of the gas flame can, and will yet be more largely made the means of alleviating. With scarcely an exception, the installations we have had of the electric light in this country for the illumination of extended areas, instead of being testimonials in its favour, have been just so many condemnations of it. They have gone largely to prove how far it is at present from being a dependable and useful light; and they have also revealed how much of ignorance and presumption were concealed beneath the language of *dilettante* scientists, who talked glibly of parcelling out our towns into electrical lighting areas for the benefit of hungry companies. It makes one ashamed to look back to the time when the Parliamentary Committee on the electric light was sitting, and remember the exaggerated and harmful nonsense that was spoken on the subject by men styling themselves leaders in science. I cannot help contrasting their behaviour with that of George Stephenson, in the earlier years of the century, when placed in a similar position in the witness chair of a Commons Committee. An honourable member put the question to him, with a grave face, and in an incredulous tone, 'Now, Mr. Stephenson, do you really think you will be able to run your locomotive engines at a speed of twelve miles an hour?' 'Yes,' replied the great engineer, 'I believe we shall be able eventually to run them at a speed of *twenty* miles an hour.' That was a modest boast, as he had proved the fact before, and he kept well within his actual experience; the others palavered about something of which they were profoundly ignorant. That word 'installation,' by the way, is a high-sounding word, and catches the ear of the unwary; but it is not business, and unfortunately it grates on the ears of a good many sufferers. We usually associate the idea of stability and permanence with the word installation. We speak, for example, of the installation of a bishop; and, when the act or ceremony of installation has been completed, the said bishop begins to fulfil, and continues to fulfil his functions, and perform the duties of his office with continuity and some degree of success, if not always with perfect success—for even bishops are not perfect—yet with such measure of efficiency as poor human nature is capable of. But electric lighting installations hitherto, with but rare exceptions, and these in isolated buildings, have been synonymous with failure. It is not in an assemblage of gas engineers that scientific discovery and progress will fail to meet with due recognition. They view the electric light neither with envious nor unfriendly eyes. It is only the quackery and pretension which are associated with it that calls forth their animadversion; and to these, not a moment too soon, the eyes of the public have been opened. If I might presume to act the part of candid friend of the electricians, I would say—as I said at the very beginning, when the wonders of the dynamo were first displayed—that until you can accumulate and freely distribute a reserve of electrical force, your method of lighting can never prove a success. Engines and belting are not to be depended on, even when they are in duplicate. In short, what electricians should aim at is to make their light as staying as gas light. When they succeed in making the electric light as *staying*, they will have within their grasp the power of making it as *paying* as gas light; but in my humble opinion not before. I am not going to say—what it has become the custom to say—that this spoilt child has 'a great future before it' in the illumination of our towns and their innumerable dwellings. That to me is not at all apparent. If I saw any signs of the fact, assuming it to be a fact, I would be justified in saying, and I would say, that I believe it has a great future before it in that respect. With all the circumstances before us, however—the lengthy record of failure and disaster—it is a mode of talking about things which I do not care to adopt. Doubtless it might be considered the better part of valour to venture on a prophecy of the kind, though it is only a mercenary way of making the best of both lights, as Mr. Facing-both-ways tries to make the 'best of both worlds.' It boils the hard peas of criticism, and saves one's scientific reputation; and then it casts the glamour of the seer about one's speech to profess to look far ahead into the future. I prefer to view the hard facts of the present; to use these as my text, and to put the question, 'Show us your credentials?' Aerial navigation may have a great future before it. There are enthusiasts who have been predicting that for a century; at present it is not very apparent that it has. To say that a thing has 'a great future before it' is often a way of saying that it is a present failure, and that is hardly complimentary. If I were an electrician I would say 'Spare us patronage of that kind.'" Our readers will be able to sift many of these assertions for themselves.

COMMON MISTAKES IN ELECTRICITY AND MAGNETISM.

BY G. W. VON TUNZELMANN, B.SC.

I.—MAGNETISM.

While looking over the papers in magnetism and electricity worked by students of science classes at the May Examination of the Science and Art Department during the last few years I have been struck by the frequent recurrence of certain mistakes and misapprehensions of a very elementary character. I think it may be of use both to science teachers and to students to call their attention to some of these, which I have specially noted either in these papers or in others which I have had occasion at different times to examine.

Before going into details, I should like to point out that while some of these show clearly that the students have been taught things that are actually untrue, many of them are due to candidates having merely learned to describe certain stock experiments, and to *repeat* explanations of them given by the teacher without having thought out and mastered the principles on which they depend. I will now go on to consider the chief points in detail.

Fundamental Ideas of Magnetism.—A great many blunders arise from pupils being introduced to the conception of "magnetic fluids," or "imaginary magnetic matter," before they have thoroughly mastered the fundamental facts of magnetism. Thus, if they are told that the action of a magnet in the form of a long thin bar may be represented by supposing equal quantities of the two kinds of "magnetic matter" placed at the extremities of the bar, before they fully understand what happens when a magnet is broken into several pieces, they are liable to fall into the common error of explaining other magnetic phenomena by the actual accumulation of something, which they call "magnetic fluid," at the extremities of a magnet, whereas this experiment, if properly understood, would show them that if magnetic phenomena were really due to the existence of such a "fluid," then this "fluid" could not pass from one molecule to another, and therefore they would understand that the accumulation of "magnetic fluid" at the poles of a magnet is not a physical fact, but simply a convenient way of representing the forces exerted by the magnet upon other magnetic bodies.

Distinction between Magnetic Substances and Magnets.—Simple as is the distinction between magnetic substances and magnets, the two are often confused.

The teacher should see that the learner clearly understands that, while any body which is capable of being acted upon by neighbouring bodies in virtue of their magnetism is a magnetic substance, it is a magnet only if in itself it possesses magnetic properties. The mutual actions of these bodies on each other should be fully explained and illustrated, viz. :—

That magnetic substances exert no special action upon each other in virtue of their being magnetic substances;

That the action of magnets on magnetic substances is attractive only;

That the action of magnets on magnets is, under different circumstances, either attractive or repulsive.

Magnetic Induction.—In approaching the subject of magnetic induction, the first thing to impress on the mind of the learner is that whenever a magnetic substance is brought into contact with, or close to, a magnet, it becomes itself a magnet, and remains so until it is removed from the neighbourhood of the magnet, and that in some cases it retains a portion of its magnetism after removal.

Thus, consider the fundamental fact that a magnet attracts a piece of soft iron in its neighbourhood; suppose, for example, that a small iron ball is attracted towards the north end of a magnet. It should first be explained that the effect on the ball is to make it a magnet with its south end next to the north end of the magnet, and its north end more remote. The learner will then be able to understand that, as the distance between the unlike ends is less than that between the like ends, the attraction between the two bodies will be greater than the repulsion, and, therefore, that the observed effect, being the difference between the attraction and repulsion, must be attractive.

As an example of the necessity of the teacher's making sure that this is clearly understood, take the following question :—

A small iron ball is suspended from the north end of a bar magnet; state and explain the effect of placing a similar bar magnet by the side of the first, (1) with similar ends adjacent, (2) with dissimilar ends adjacent.

Answer: The first magnet will magnetise the ball, making the part in contact the south end, and the remote part the north end. The second magnet will, in the first case, act in a similar manner on the ball, which will become a stronger magnet, and, therefore, the attraction will be increased so that there will be no observed effect.

In the second case the second magnet will tend to make the part of the ball in contact with the first a north end, and the remote part a south end. If these two effects were equal the ball would become entirely neutral, and, therefore, being no longer attracted, it would fall. In the case in question the two magnets are of equal strength, but the second is slightly more remote, therefore the ball will remain magnetised in the same sense as at first, but *much* more weakly, and therefore it will fall, unless very small in proportion to the size of the magnets.

The mistake most commonly made in answering a question such as this consists in supposing that the ball falls off when dissimilar ends of the magnets are adjacent, because all the magnetic force of the magnets is employed in attracting each other. As a matter of fact, the magnetising effect of the north end of the first magnet upon the ball will be very slightly increased by the neighbourhood of the south end of the second magnet, as the effect of the second magnet upon the first will be to magnetise it still more strongly, and will therefore increase its magnetising power.

A student who clearly understands the result of such an experiment as this will have no difficulty in satisfactorily explaining the advantage of storing magnets, either with their opposite ends in contact or connected by a "keeper."

Explanation of Magnetic Induction.—I have already pointed out the error which students often fall into in explaining induction by means of "magnetic fluids" from not understanding that the theory is only admissible with the restriction that the fluid is not to pass from one molecule to another.

My own opinion is that with elementary students it is better not to make use of "magnetic fluids" at all, as Weber's "Theory of Magnetic Induction" is very much more satisfactory as an explanation, and is more easily understood. "Magnetic fluids" or "imaginary magnetic matter" may, therefore, very well be left alone, except with advanced students of mathematical electricity, and in their case it is of great use, not as an explanation of what is happening in the magnetised body, but simply as an artifice by means of which magnetic problems may often be put into a convenient form for mathematical treatment.

As Weber's theory is not always to be found in the elementary works commonly used, a short sketch of it may not be out of place here.

Weber's Theory of Magnetic Induction.—Let us suppose that each of the molecules of which a magnetic substance is built up is itself a magnet, but that the axes of these small magnets are turned in every possible direction; the magnetic actions of the molecules will then neutralise one another, so that the body will not act as a magnet, but if either pole of a magnet be brought near to it this pole will attract the unlike poles of the molecules and will repel the like poles, so that the molecules will tend to arrange themselves with their north poles pointing one way and their south poles pointing the other way. The molecules will then all act together, and will form a magnet with the portion nearest to the magnetic pole of unlike polarity to it.

It is clear that this theory will necessarily account for any fact which can be accounted for on the theory of "magnetic fluids," and in addition to its being more comprehensible as an actual explanation it has the advantage of experimental evidence in its support.

For example we know that—

(1) Magnetisation is facilitated by striking the body to be magnetised, or by heating it.

Digitized by Google

(2) Bodies, when magnetised, usually undergo a slight change of shape without being altered in size, becoming either longer and thinner or shorter and thicker.

(3) When a piece of iron is suddenly magnetised, or demagnetised, a slight sound is heard.

These facts are very simply explained by Weber's theory, while the theory of magnetic fluids could only account for them by the introduction of additional suppositions.

I will conclude the present paper by suggesting to teachers who are sending up pupils for examination that it would be well to caution them in answering questions, to make quite clear what they mean by the north and south ends of a magnet.

According to the system in ordinary use, the north end of a magnet is the end which would turn towards the north if the magnet were free to move in a horizontal plane. Sir William Thomson calls the end which turns towards the north the south end, because its magnetism is similar to that of the earth's south pole.

If candidates use Sir William Thomson's method, they should be careful to make it clear, as otherwise their answers may be misunderstood.

IMITATION OF THE PHENOMENA OF ELECTRICITY AND MAGNETISM BY MEANS OF LIQUID OR GASEOUS CURRENTS.*

BY M. C. DECHARME.

(Continued from page 67.)

II.—Physical Effects.

1. *Imitation of the Lines of Force obtained with Electric Currents or with Magnets.*—I need only mention the more important of the experiments.

a. To imitate the *lines of force of an electric current in a plane perpendicular to its direction* it is only necessary to blow softly, by a slender, tapering, glass tube, a continuous current of water perpendicularly to a glass plate covered with a thin layer of minium diluted in water; the point of the tube being fixed at a distance of several millimetres from the plate. There is then obtained, around the point of contact of the jet with the plate, a considerable number of concentric circles, formed by particles of the minium, which are very similar to the figures formed by iron filings under the influence of an electric current. Instead of minium very fine iron filings may be employed; the same phenomena are apparent, but for the gain in analogy there is a perceptible loss in fineness of detail.

b. To imitate the *lines of force of an electric current in a plane parallel to its direction, a current of air* should be blown by a tapering tube, held vertically, upon the deposit of minium. The tube is then turned rapidly in a direction parallel to the plate of glass, so that the current may, so to speak, be emitted horizontally. That being done, a series of very short and very compact lines, perpendicular to the direction of the current, forms upon the deposit of minium. The phenomenon is similar to that which occurs when a sheet of paper sprinkled with iron filings is strongly electrified.

c. The lines of force of two parallel electric currents, of the same sign, in a plane perpendicular to their direction, may be imitated by employing two tubes containing water, as in experiment *a*.

d. The imitation of the *lines of force of two parallel electric currents, of opposite sign, in a plane perpendicular to their direction*, is obtained by using two tubes, one of them tapered to emit the liquid, and the other adapted to suck the water and the minium. By the simultaneous action of these tubes, one of which is placed at a distance of several millimetres from the plate, and the other in actual contact with it, a figure is produced which clearly demonstrates the two effects of polarity. The aspiration corresponding to positive electricity, and the blowing to negative electricity.

e. An imitation of similar magnetic phenomena produced by magnets either separate or combined may be effected by similar means; the tubes, however, should not be tapered.

2. *Imitation of the Forms and of the Effects of Electric Discharge.* Tufts, feathers, and other forms taken in the discharge of electricity, rectilinear sparks, ramified, sinuous, &c., are readily imitated by blowing, through a tapered tube, a current of water or of air, in the plane of a plate covered with minium in suspension, and by then displacing the tube until it is parallel to the plate. The star-like spark is exactly imitated by strong suction, through a very small fixed tube, of the minium until it is almost drained. The imitation of the figures of Lichtenberg presents this peculiarity, the effect of the aspiration is that of *positive* electricity, and the breathing or blowing to that of *negative* electricity, results which are not without their importance. If, by the aid of a tapered tube, approached to within about $0^m \cdot 01$ of the plate covered with its layer of aqueous minium, a current of air be directed upon the plate, and the tube be then displaced horizontally, a narrow ridge is produced; one part of the disturbed matter rises to the surface, whilst the other beneath, fixed and motionless, is disposed in fine lines, very concise and compact, perpendicular to the axis of the ridge, and similar to the effect which is produced when an electric discharge traverses a metallic wire and volatilises it between two plates of glass.

The stratifications of the electric light in rarefied gases can also be imitiated by means of the same apparatus and the same methods as in the preceding experiments; a tube more or less large, according to whether the water is to flow or to be blown, is moved horizontally and with great quickness above the plate with its layer of minium, and the current is by this means shown in a straight or a curved line upon the pulverent deposit. For certain effects a current of air may be substituted with advantage for a current of water. The imitation is still more exact when interrupted currents of air are employed, either with a single tube or with twin tubes. The experiment, however, which best illustrates the subject is the following:—A glass syphon, provided with a long arm of india rubber, is arranged vertically, its arm touching the bottom of a vase full of water. As soon as the level of the liquid arrives at a distance of several millimetres from the bottom, a number of infinitesmal bubbles of air penetrate into the tube, and set up a sharp hissing noise. As the flow increases the volume of the bubbles is augmented, and the sound diminishes in height and intensity; at a certain moment the bubbles acquire a speed at which they appear to be fixed and constant, as is the case with the stratifications of the electric light in the Geissler tubes. To complete the illusion, the noise which accompanies the phenomena is analogous to that of the interruptor of the induction coil. *L'éclair en chapelet*, described by M. Planté, can be reproduced by moving the tube of water rapidly above the layer of aqueous minium in such a manner that the drops may be shown in juxtaposition upon the plate. One can also realise, by means analogous to the preceding, various forms which bear a striking resemblance to those of the water-spout, the aurora borealis, and the tails of comets, &c.

III. Chemical Effects.

Imitation of the Electro-chemical Rings of Nobili.—Of all our hydro-dynamical imitations of electrical phenomena this is, perhaps, the most remarkable, and the most conclusive in favour of the similarity of the liquid and the electric currents. The experiment may be arranged in the following manner:—Upon a horizontal plate of glass, covered with a thin and uniform layer of minium in suspension in water (or of any other heavy and insoluble powder such as white lead, vermilion, sulphate of baryta, &c.), is projected a small stream of water, falling from a graduated glass tube, held vertically at a distance of $0^m \cdot 01$ to $0^m \cdot 10$.

Under these conditions a series of concentric rings, more or less in number, unequally spaced, and of different thicknesses, formed by the movement of the pulverent deposit under the impulsive action of the liquid current, are produced upon the plate, around the point of the jet. These rings present, ordinarily, well defined outlines and variations of style which are remarkable for their fineness. Frequently there are to be distinguished very slender rays which traverse the whole concentric system and form symmetrical and varied designs of great delicacy.

The similarity of these rings to those of Nobili will readily be recognised. The clearness, the regularity, the delicacy of the rings, and their beauty as a whole, depend upon the nature

* From the *Journal de Physique*.

Digitized by Google

of the powder in suspension, that is to say, upon its density and upon its fineness. The narrower the tube and the more closely it approaches the plate the better defined the rings become. The number and the diameter of the rings vary with the length of the column of liquid and the height of the jet; usually there are four or five, but not unfrequently eight or ten. All the rings of one figure are not of the same clearness; those which are furthest from the centre are the most regular and those in which the outlines are the best drawn. As with the electro-chemical rings the *wave* form of propagation is very apparent.

The only essential difference between the two sorts of rings is that those of Nobili present the gradations of colour of the rainbow. This difference, however, is not altogether absolute, because the primaries are sometimes alternately clear and obscure; and, on the other hand, the hydraulic rings (obtained with perfectly white sulphate of baryta) are not destitute of colour, as may be seen upon examination. In operating with two, three, four, &c., tubes symmetrically disposed, there are produced upon the layer of minium the *equipotential figures* electro-chemically obtained by M. A. Guébhard*, and compared by him to the hydraulic level curves of Lamé.

The imitation of electro-chemical rings which seems the most rational and most akin to those formed by aid of the electric current is perhaps produced by the use of a *continuous current of water*. The following are, briefly, the results I have obtained by this means :—

The current of which I made use flowed from a cylindrical or conical convergent tube (of $0^m{\cdot}002$ to $0^m{\cdot}007$ in diameter, inferior orifice), and fell vertically upon a horizontal plate of black glass, simply *moistened* throughout its extent. The actuating tube was fixed at such a height that at the distance

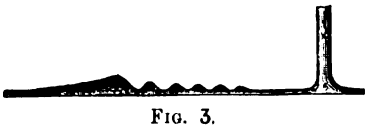

Fig. 3.

where the jet met the plate (a distance variable to $0^m{\cdot}10$ or $0^m{\cdot}15$ in the experiment under discussion) it was continuous, an essential condition. Then the current fell without noise, and produced, around the point of the jet, liquid rings which were perfectly steady. These concentric waves, of which the diameter and the number varied with the experimental conditions, are spaced in exactly the same manner as the electro-chemical rings. Fig. 3 represents in section the formation and the separation of the liquid rings in the case of a single tube.

(To be continued.)

CORRESPONDENCE.

ARMATURE WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Wilkinson, in your last issue, says that I arrived at an incorrect result when comparing the length of wire on Siemens and Gramme armatures. To avoid the use of "blind mathematics," a subject treated by him in a letter appearing on the same page, I would ask him to take a piece of string, and try the winding on two small models. He will then see that my formulæ are correct. Apparently Mr. Wilkinson has made the mistake of taking n to mean the number of complete turns on the Siemens armature, which would give $2n$ wires on the outside, whilst I take n to mean the number of wires on outer circumference of armature counted all round. To make the comparison fair, this number must be the same in both armatures.—Yours, &c.,

Gisbert Kapp.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to my letter of last week, if we take n as the number of half turns wound on the drum, *i.e.*, the number of wires counted on its periphery, the expressions

$$n(b + 1{\cdot}3d.)$$

for the length of wire coiled on and Mr. Kapp's final equation

$$b = {\cdot}95d$$

are quite correct; the wording, however, employed would lead one to suppose n the number of complete turns on the drum, especially as Nt is previously employed for the number of external wires.

The above relation between the length and diameter of both armature cores is therefore that with which the resistances of both will be equal, when the number of wires on the *outer circumference* of each (not the number of turns) is the same.—Yours, &c.,

H. D. Wilkinson.

School of Electrical Engineering,
Hanover-square, W.

"EDISON'S LATEST INVENTION."

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In last week's number of *The Electrician* you head one of the paragraphs in your "Notes" "Edison's Latest Invention." I have already noticed that Mr. Edison, in conjunction with Mr. Gilliland, has patented in this country "means for signalling or telegraphing between railway trains or between trains and stations by induction," and I presume that your paragraph refers to this patent.

On November 8th, 1883, I read a paper before the Society of Telegraph-Engineers and Electricians, on "Volta-electric Induction," and, at the conclusion of that paper, suggested the way in which induction might be employed for signalling between trains in motion and fixed points, viz: Vol. XII., p. 472, of the *Journal* of the Society of Telegraph-Engineers and Electricians. I much regret that gentlemen connected with the electrical work of the railways in England have not taken more interest in the subject, as I am confident it would form a cheap and efficient adjunct to the present system of railway signalling. Mr. Edison is wrong in supposing that he is the only person who has produced inductive effects 35ft. from the primary source, for, in my experiments, I have far exceeded that distance.

I also wish to call attention to another of your notes—"Hearing the Earth's Magnetic Induction." Similar experiments to those described in that paragraph were experimentally demonstrated during the reading of my paper already referred to, viz., page 469 of the *Journal* named above.

I trouble you to record this, as perhaps when these germs are fully developed it may be convenient to be able to readily fix dates.—Yours, &c.,

Willoughby Smith.

Wharf-road, City-road, June 15, 1885.

BLIND MATHEMATICS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Wilkinson, in the first of his two numbered instances, attributes the greater heating of the platinum link (in series with a silver link) to its greater resistance. Quite so. And yet the formula $H = \frac{E^2}{R}$, to which I am objecting (and which for the moment he wisely abandons), would teach us that resistance is *unfavourable* to the development of heat.

Am I not correct in supposing your correspondent's real position to be this, that there is greater *local* E.M.F. acting upon the platinum than upon the silver, and as "E" tells in favour of heat at a squared rate, the counter effect due to the sixfold resistance is eclipsed? But if E is to mean not the E.M.F. of the battery, but the local difference of potentials at the extremities of the heated wire, then are we merely in the fire instead of in the frying-pan. For why is there a greater difference of potential in the case of the platinum? Precisely because its resistance is greater. In other words E^2 involves R, which is therefore implicitly above the line as well as below in the fraction $\frac{E^2}{R}$, and the formula is a degree more complex than its parent $H = C^2R$, which it was supposed to simplify.

I am in perfect agreement with Mr. Wilkinson in his facts about the glow-lamps, and admire the prettiness of his illustrations.—Yours, &c.,

E. Aldred Williams.

ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If Mons. Adolphe de Bromwere refers to page 529, Vol. XIII., of *The Electrician*, he will there find a brief account of what was not merely a *tour de force* but a practical installation carried out by Messrs. Gaulard and Gibbs, and which included an 80 kilometre circuit between Turin and Lanzo.

Being an exhibit it could not well be permanent, but that it was successful could not be doubted by anyone who, like myself, had an opportunity of observing closely its regular working.

Messrs. Gaulard and Gibbs will doubtless supply your correspondent with any further information he may require.—Yours, &c.,

J. WESTBEECH KEMPSTER.

Chelmsford, June 15, 1885.

THE LATE PROF. FLEEMING JENKIN, LL.D., F.R.S.

The Scottish school of physical science has suffered a heavy loss in the unexpected death, at the comparatively early age of 52 years, of Mr. H. C. Fleeming Jenkin, the distinguished Professor of Engineering in the University of Edinburgh. Since the close of the college session until about a week ago Professor Jenkin was in London actively engaged in developing his recent inventions in electric locomotion, when he returned to Edinburgh to undergo a slight surgical operation. Blood poisoning followed, and after a short illness he died on Friday. The only son of the late Captain Charles Jenkin, R.N., and born at Stowting Court, Kent, in 1833, Mr. Jenkin went to Scotland at an early age, where his first school was Dr. Burnett's, Jedburgh, and his second the Edinburgh Academy. At the age of 13 he went to school at Frankfort, in the following year to Paris, and finally graduated as M.A. of the University of Genoa, where he began his engineering career in 1850. An apprenticeship of three years under Sir W. Fairbairn, of Manchester, followed, and after a varied experience of practical work Mr. Jenkin entered the service of Messrs. Newall, of Birkenhead, in 1857, while they were engaged in the manufacture of the first Atlantic cable. He was entrusted with their chief engineering and electrical work, and in this way had his energies bent in the direction he was afterwards to follow with signal success.

As a pioneer of ocean telegraphy he soon made the acquaintance of Sir William Thomson, and assisted him in the development of the instruments by which the transmission of electric messages over long distances at sea became for the first time practicable. Up to that date electricity had been almost wholly an affair of the text-book and the laboratory, and, though the principles of electrical measurement were known by a select few natural philosophers, no convenient or generally accepted units existed in which electrical magnitudes could be expressed. At the suggestion of Sir W. Thomson, a Committee of the British Association was appointed to determine practical electrical units. Of this committee, whose labours lasted for many years, Mr. Jenkin was one of the most active members, and as secretary wrote many of their reports.

Subsequently Mr. Jenkin entered into partnership with Sir William Thomson as a telegraph engineer, and many of the great submarine cables have been constructed and laid under their supervision. Besides this he joined forces with Sir W. Thomson and with the late Mr. C. F. Varley as patentees of electrical instruments, and as their instruments were the only ones by which signalling through long cables could be economically performed, the patents proved extremely valuable. Recently Prof. Jenkin attacked the problem of electric locomotion with characteristic energy and originality. While other inventors were seeking to devise an electrical locomotive which should take the place of the steam engine on an ordinary railway, he conceived that the line itself should be entirely reconstructed, and the method of working reorganised to suit the conditions of electrical transport; and in this way he invented the system to which he gave the name of Telpherage. During the last two years of his life he was experimenting on this system, and perfecting its details with the utmost ardour, and the first Telpher line was actually in process of construction when he died. Besides his numerous electric patents, he has made inventions in bridge work, hydraulics, mechanical methods of transmitting power, and heat engines. He was juror in Physical Apparatus at the Exhibition of 1862, in Engineering at the Paris Exhibition of 1878, and in Electricity at the Health Exhibition last year. In 1866 he was elected Professor of Engineering in University College, London, but resigned the post in 1868 to take the Chair of Engineering then founded by Sir David Baxter in the University of Edinburgh, and there he has since taught with the greatest success. His class room has already proved the nursery of at least two younger Professors. Neither his duties as a teacher nor his occupations as a consulting engineer, an inventor, and a scientific witness and assessor at the courts were able to engross his activities.

From 1859 onwards he wrote some fifty papers on scientific and social subjects, as well as several text books. Of these last, the principal one—his book on "Electricity and Magnetism" in Messrs. Longman's series of text books of science—which has passed through many editions, and been translated into several foreign languages, is generally accepted as the best existing elementary treatise on electricity. His scientific papers are for the most part to be found in the *Transactions* and *Proceedings* of the Royal Societies of London and Edinburgh, of the former of which he was elected a Fellow at the early age of thirty-two, while of the latter he was made Vice-President in 1879. His papers exhibit much originality. One, published in 1878 (which gained the Keith Prize of the Royal Society of Edinburgh), lays the foundation of an entirely new dynamical theory of machines, which is as much in advance of the merely kinematical analysis of Reulaux as that was in advance of the fragmentary treatment which preceded it.

Apart altogether from his scientific achievements, Professor Jenkin was in many ways a man of remarkable power, and even more remarkable variety. As an accomplished linguist, a *litterateur*, a critic, a metaphysician, a sportsman, no subject seemed out of his ken. Whether the talk was of technical education or the costume of the Greeks, of French plays or the freedom of the will, Mr. Jenkin was sure to contribute a fact, a theory—a paradox, perhaps—but still something fresh and suggestive. Of him even more than of most men it might be said that only his intimate friends really knew him, and his intimates were for the most part specialists in literature or art, or in anything rather than the subjects that formed the main business of his own life. Of his literary work the pages of the *North British Review* for 1868 contain examples, among which an article on the "Atomic Theory of Lucretius" may perhaps be specially named. Other of his writings treat of Darwinism, education, economics, and hygiene. In this last subject he did more and better work than merely that of the pen. In 1877 he organised the Edinburgh Sanitary Protection Association, a co-operative society which secured for its members the benefit of periodic inspection and skilled advice regarding drainage. The idea was novel, and a man of less energy would have found the opposition and prejudice of the public strong. He soon launched the Edinburgh Association on a career of assured prosperity, and then promoted the formation of similar societies in London and other places. A like society was founded in Dundee a little more than a year ago, of which, as of many of the others, Prof. Jenkin was honorary consulting engineer. With other titular distinctions, Prof. Jenkin was an LL.D. of Glasgow University, and an honorary member of the Société Professionelle d'Hygiène of Paris. He leaves a widow and three sons.

We have to thank Prof. A. J. Ewing for the above memoir of the late Prof. Fleeming Jenkin. In addition to what is here stated we would refer readers to the "Electricians' Directory" for 1885 for an epitomised notice of the career of Prof. F. Jenkin. Those who have heard Prof. Jenkin expound the probabilities of the telpherage system will not soon forget the enthusiasm of the man. So far as we are aware the first really public exposition of the scheme was made at the B. A. meeting at Southport, when Prof. Jenkin read a paper in which the telpherage system was explained, and the apparatus shown. More recently at the Society of Arts the system was described, and a model will be found at work at the Inventions Exhibition.

SECONDARY BATTERIES.

The paper which we reprint in this issue, read before the Institution of Civil Engineers, will perhaps draw attention anew to a subject which for a time has been under a cloud. The institution has awarded the "Miller Prize" to this essay, and we do not hesitate to say that professed electricians will agree that the author's work is worthy of such recognition.

The essay bears internal evidence of experience with various forms of the secondary battery, and for this reason the opinion expressed in the concluding sentence has great weight. The author says:—"When once they (secondary batteries) have been so far improved as to be looked upon as trustworthy, a great and lasting impetus will certainly be given to the utilisation of electricity for motive power as well as for lighting purposes." A subject which might well be suggested for the consideration of some of our practical electricians is an exhaustive discussion of the purposes to which secondary batteries might with advantage be put, and the special requirements of each case. One great advantage to constructors is in having a definite object in view, and we now know sufficient of secondary batteries to feel sure they can be modified for specific purposes within certain limits. At the present time secondary batteries have received comparatively but limited patronage. This arises from two causes. The first of these is due to the highly-coloured declarations as to the advantages and state of perfection of the Faure accumulator set forth by promotors of companies. Public opinion failed to grasp the difference between the hopes inspired by a satisfactory laboratory experiment and the matter-of-fact capabilities of every-day work. The idea became quite common that at last an apparatus was devised which would give an efficiency of from 80 to 99·9 per cent. The coolest heads lost their influence, and from the introduction of the Faure accumulator to the present moment purchasers have been seeking not only for what they cannot now obtain but for that which scientific progress is not likely to give them for many years to come. If our forefathers had calculated the theoretic value of one pound or one ton of coal, and refused to entertain the idea of purchase of a steam engine because not one-twentieth, much less one-fiftieth, of that thereotic value could be usefully obtained by such means, the progress of the world would have been somewhat delayed.

The same practical considerations which worked for the introduction of steam are even now working for the introduction of secondary batteries. Many cases arise in which the use of such apparatus is expedient, principally, perhaps, in temporary installations. The use herein is being greatly extended, and is attended with more and more success, till in these cases a breakdown of any kind is almost unknown. Similar success has not hitherto attended the introduction of the more scientific forms of the secondary battery into permanent lighting, though even here breakdowns are becoming more and more rare. The experience already gained in the use and construction of such batteries has led to improvements whereby their life has gradually been increased from hours and days to weeks and months. The second cause to which we would refer is a corollary to the first, in that promises of perfection were made before any experience in manufacture had been gained. Hitherto most attempts to use secondary batteries in large installations have failed because, without rhyme or reason, some of the plates of the battery broke down. The manufacturers were powerless to obtain security against failure. Mr. Howard refers in his essay to the use of secondary batteries as a stand-bye in case of an accident to dynamo or engine, but batteries can only be so used when they may be trusted without fail to work if called upon. No doubt we shall be told that many installations have been made with secondary batteries. We do not dispute the fact, but we dispute the value of the apparatus in these installations, and maintain that it would have been cheaper had reliance in the first instance been placed solely upon the dynamos. The cost has been so great that neither shareholders nor the public will ever get an adequate idea of what it has been, and we are inclined to think that neither directors nor managers have the least inkling of the reality.

It has previously been stated that Mr. Howard's essay is an epitome of the author's experiences, and it undoubtedly contains a large number of practical hints of great value. Exception might, however, be taken to the information as given in the table of storage capacity. The Planté cell, for example, at its period of highest efficiency should give a higher efficiency than the Sellon-Volckmar. In fact the efficiency of the Planté cell varies from a very small to a very high efficiency, and if from a purely theoretical point of view we were asked to name a cell that should give the highest collective efficiency from birth to death, we should couple the simple lead plate and the compressed lead plate as most efficient. The simple lead plate, however, is not generally practical, in that its storage capacity at first is almost *nil*. It requires a long time, and care, in its formation, and the material taken away to obtain porosity serves no useful purpose. We might also point out that a theoretically perfect cell, so far as storage capacity is concerned, is absolutely valueless, unless indeed, Mr. FitzGerald's idea is practically realised that the active machine be in contact with a good conductor which shall remain unacted upon and make good contact under all

Digitized by Google

conditions. Mr. Tribe is said to have obtained some very satisfactory results in this direction, but so far we have heard of nothing in this direction except laboratory experiments. Sufficient will have been said for the purpose in view to direct attention to a flagging subject, to show the importance of success, and the many asides that have to be considered by constructors in order to get practical perfection.

SECONDARY BATTERIES.*

BY FRANK GEERE HOWARD, STUD.INST.C.E.

Among the most important discoveries of recent years few have received so much attention, and had such bright prospects, as the accumulators of Planté and their various modifications. All sorts of wild schemes were set afloat for their utilisation, the principal one being to talk about the time when electricity by means of these accumulators could be delivered every morning from house to house like milk. The result of this would have been much the same as if a water company attempted to supply water to its customers by sending round so many gallons every day in carts, or better still a gas company delivering bags full of gas ready for use, one being as impracticable as the other. These ideas were soon dispelled, and then followed disappointment, and of course general condemnation of secondary batteries.

But all this time inventors had been steadily turning their attention in this direction. Many improvements have been introduced, and numbers of difficulties, before considered fatal to them, have been overcome. They are still far from perfect, though it may yet be expected that accumulators or secondary batteries will play the most important part in all extended systems of electric lighting, transmission of power, and the satisfactory solution of the utilisation of wind and water power.

The earliest form of accumulator was a voltameter worked backwards, and was first observed in 1801 by the French chemist, Gautherot. Two years later Ritter, in Germany, carried out a number of experiments in the same direction, and endeavoured to utilise the reaction; he employed for this purpose two plates of gold, separated from each other by flannel kept moistened with acid, and charged by an ordinary Volta's pile. If two pieces of platinum be immersed in dilute sulphuric acid and connected to the two poles of a battery, so that a current be sent through them, the liquid will be decomposed, hydrogen being given off at one plate and oxygen at the other. If then the battery is disconnected and the plates circuited through a galvanometer, it will be seen that they give out a current in the opposite direction to the charging current.

Becquerel first pointed out the real cause of the returned current, upsetting the original theory that the plates absorbed the current during the charging, and gave it up again during the discharge. He showed that the returned current was not due to the storage of electricity, but to the presence of substances having chemical affinities for each other, derived from the decomposition going on during the charge.

If two sheets of ordinary lead be placed in dilute sulphuric acid, and a current be sent through them, a dark brown deposit will form upon the plate connected to the positive pole of the charging battery, due to the formation of peroxide of lead on the surface of that plate, whilst the other will be reduced slightly to spongy lead. Upon disconnecting these plates from the charging source, and circuiting them through a galvanometer, a current will flow from the brown or peroxidised plate to the other reduced plate.

The result is the reduction of the peroxide of lead on the one plate to oxide, and then to sulphate of lead from the presence of the sulphuric acid in the solution; and of the spongy lead to sulphate of lead. Upon recharging, the anode or brown plate, attached to the positive pole of the charging source, will again become peroxidised, and the cathode or other plate reduced to spongy lead. The sulphate of lead will thus disappear from both plates. The plates are thus continually oxidised and deoxidised as they are charged and discharged.

This is a secondary battery in its simplest form, and all accumulators are based upon this principle. Lead has proved by far the best metal for the purpose, because it forms an almost insoluble oxide; a few other metals are nearly insoluble, but lead has the advantage. It is better than silver or manganese, for the reason that its oxide is less soluble than either of them.

The initial electromotive force of a freshly prepared cell when charged is 2·25 volts, but this drops after the first few minutes of the discharge to a little less than 2 volts, which may be taken as the normal electromotive force of a cell made up of peroxide of lead, spongy lead and dilute sulphuric acid. The constancy of the electromotive force of a cell varies considerably with the rate of discharge. If it is run down, or discharged, at a very rapid rate it falls off very quickly; whereas if only a small current be taken out the electromotive force will remain constant for a long time, though the loss on the negative plate or anode from local action will be greater. The strength of the electrolyte or solution varies considerably during the charging or discharging of the cell. When the cell is fully charged the solution is strongest, and when discharged weakest. From this it follows that the internal resistance of a battery is lowest when the electromotive force is at its highest, and the converse. Dr. Frankland has endeavoured to utilise this change in the specific gravity of the solution, to indicate the condition of the cell, and has found that a change of 0·005 in the specific gravity was equal to a storage of 20 ampere hours. This method of determining the state of the cell does not in practice give very good results, on account of the difficulty of getting the solution in the cell to circulate freely, so as to be of the same density throughout.

The first practicable form of accumulator was that of Planté, made in 1860. He took two sheets of lead, and, placing them in dilute sulphuric acid, passed a current through them for some time. Then disconnecting the cell from the charging source, he discharged it, and again charged it, but this time in a reverse direction; so that the lead plate, formerly connected to the positive pole of the charging source, was this time connected to the negative pole. A number of charges and discharges were thus alternately effected until the plates were rendered sufficiently porous to give a satisfactory storage capacity. Planté found that it was necessary to continue this process for some months before a battery was fit for use. Of course when the battery was used the current was sent through it always in the same direction. The reverse charges were only employed to "form" the plates, or render them sufficiently porous to hold a charge. Unfortunately this form of cell, simple as it is, does not store much electrical energy, except when very thin plates are employed, and these soon become brittle and liable to fall to pieces through being entirely converted into peroxide of lead and thereby losing their stability.

According to Géraldy a Planté cell containing 1·445 kilogram of lead is capable of storing 4,983 kilogrammetres of energy, or 11,329 foot-pounds per lb. of lead. De Meritens modified the Planté cell by making the plates out of a number of thin sheets of lead laid one upon the top of the other, and soldering their edges together, thus obtaining plates composed of a number of layers of thin sheet lead.

Kabath again modified this by taking long thin strips of lead which he corrugated by passing them through grooved rollers, and then interleaving them with plain strips, or ribbons of lead, folding them backwards and forwards, until a plate was formed of the required size. The drawback to this form is that the lead used is of necessity very thin, and thus soon breaks down and renders the cell useless. In both these cases the same tedious process of forming as in the Planté cell has to be gone through.

In 1880 Faure devised the plan of pasting red lead, or minium, upon plates of plain lead; this paste was rapidly peroxidised and reduced in one charge, thus overcoming and doing away with the long process of forming the Planté plates. The paste had to be held on the plates by wrapping them in flannel or some such porous material. This increased the internal resistance of the cell, and after a time the flannel began to get

* Paper read at a meeting of Students at the Institute of Civil Engineers.

Digitized by Google

rotten and fall off, causing the cell to fail. A much higher storage capacity, however, was obtained, it being 18,000 foot-pounds per lb. of lead and minium. Many improvements have been introduced by Messrs. Sellon and Volckmar, culminating in the form now manufactured by the Electrical Power and Storage Company, which consists of grids of cast-lead with holes from $\frac{1}{4}$ to $\frac{3}{8}$in. square.

The grid used for the anode is made thicker than that for the cathode. These castings are filled with a paste of minium and dilute sulphuric acid. After being dried they are placed in long troughs, filled with dilute sulphuric acid, and a current is sent through them to form them. The amount of current necessary to convert 1lb. of minium to peroxide is 70 ampere-hours, and 140 ampere-hours to reduce it to metallic lead. But as it only needs 110 ampere-hours to reduce 1lb. of litharge, this is generally employed for the cathode plate. After the current has been sent through the plates, they are taken out, washed, and stacked until required for use, when they are mounted in their respective cells, and employed for lighting or other purposes. No felt is put between these plates. They are separated from each other by india rubber bands, pieces of wood, or some similar device.

The storage capacity of this cell is considerably higher than that of the Faure type, being 48,000 foot-pounds per lb. of lead. But since the storage capacity of a theoretically perfect secondary battery is 360,000 foot-pounds per lb. of lead, even the best cell falls far short of this. The figures in Table I. against Sellon-Volckmar are the results obtained from cells specially constructed for driving electric launches, tramcars, &c. Those employed ordinarily for lighting purposes yield about 36,000 foot-pounds per lb. of lead.

Table I.—Storage Capacity of the various Secondary Batteries as regards Ratio of Work to Weight.

Name.	Storage Capacity in foot lbs. per lb. of lead.		Percentage of Efficiency.
Theoretically perfect cell...	360,000	.....	100·00
Sellon-Volckmar	48,000	.....	13·13
Crompton-Fitzgerald	24,000	.....	6·66
Faure	18,000	.....	4·99
Planté	12,000	.....	3·33

It has been proposed by Mr. FitzGerald to substitute carbon for the lead employed for establishing contact with the active material of the cathodes, where oxides of lead are used, and also to protect parts of the anodes by means of some insulating material, so as to arrest the process of peroxidation over the whole of the plates, and thus always to preserve a good contact throughout the anode. A large number of experiments have been carried out in this direction. The best results obtained were from a battery made up of cathodes composed of minium and carbon fragments, held in a punctured lead envelope, and anodes composed of spongy or finely-divided lead, also held in a punctured lead envelope, and protected by a network of insulating material, generally known under the name of Prout's glue. This form had a storage capacity of 24,000 foot-pounds per lb. of lead. Messrs. Beaumont and Biggs' battery is made up of plates of compressed spongy lead. The lead is obtained in this state by precipitation from a solution of acetate, or sugar of lead, in which solution is placed a plate of zinc. Lead, in a state of very fine subdivision, is deposited upon the zinc, from which it is scraped off, put into moulds, and subjected to hydraulic pressure. By this means plates of great porosity are obtained, which should have as high a storage capacity as any known form of battery. Of the numerous batteries in the market, nearly all are modifications of the well-known Planté type, which seems to be the best form for durability, if not for storage capacity; and the "life" of a battery is of far more importance than its storage capacity per lb. weight. The most notable battery of this class, and one coming prominently into notice, is manufactured by the Wolverhampton Electric Light Company, called the Elwell-Parker accumulator. The plates of this battery are made of sheet lead only, but before being formed they are immersed in a strong solution of nitric acid, which attacks the surface of the lead, and honeycombs it to a certain extent. Thus, according to Planté, who first patented this process in 1881, the long process of forming is to a great extent done away with. There seems, however, to be considerable doubt whether this is the case, or if the nitric acid simply dissolves the lead. In all probability the acid attacks the impurities in the lead, and thus prepares the plate in the best possible manner to receive the current. Another battery is the B. T. K., so called from the names of the inventors, Messrs. Beeman, Taylor, and King. This is a modification of the Kabath accumulator, consisting of plates made of alternate corrugated and plain strips of lead wound round and round upon themselves. Batteries of this description are being largely used in the district lighting at Colchester.

An improvement by Dr. Frankland is claimed upon the Sellon-Volckmar type of battery, by hardening the paste of minium, or other oxide of lead used in the plates, by immersing the plates in solutions of sulphuric acid of various densities during different periods. He also claims for the plates the capacity of receiving a higher rate of charge. This hardening mixture may be cast into plates or cylinders of any desired form or size. There are also many other batteries of the Planté type by various inventors. Mr. Joel has patented a plate having a considerable storage capacity. He makes the plates of lead-wool, or, perhaps more properly speaking, lead fibre, mixed with minium, and then pressed upon a cast lead plate which acts both as a conductor and support.

A battery differing in many ways from those already mentioned was that proposed by Sutton. He took two plates, one of lead and the other of copper, and immersed them in a solution of sulphate of copper. The lead plate became peroxidized, and the copper was alternately dissolved and deposited from the solution of sulphate of copper. This battery, though giving good results upon a small scale, failed when used to a large extent. The electromotive force is much lower than that of a cell composed of lead only.

The advantages of accumulators made after the Planté type over those of the Faure type are that they afford a far higher rate of discharge. This property is invaluable for many purposes, as, for instance, where numerous lamps are required to be run for only a short time. But then again accumulators of the Faure type take in a higher rate of charge than the Planté, because they have a greater thickness of working material, and also store a larger amount of electrical energy in a given weight.

The durability, or life, of a secondary battery has never been satisfactorily settled. Manufacturers assert that their accumulators will last for a number of years, but this has not yet been proved. Those of the Sellon-Volckmar type cannot, the author believes, be depended upon to last more than five or six months at the outside when they are worked regularly every day up to their full capacity. But when overcharged continuously, or otherwise improperly used, a few days will often suffice to put them out of order.

The Planté accumulator should last longer than this, but it must be borne in mind that when this battery has arrived at its maximum of efficiency it is on the point of falling to pieces. Where water or steam power is available a rough but serviceable battery may be made by taking sheets of thick lead, cutting them into plates of any required size, and mounting them in tanks filled with dilute sulphuric acid. Of course, during the first few charges the storage capacity will be very small, but this will improve every day; at the same time the cost of forming them is next to nothing. Eventually it will prove to be a most efficient battery.

The first and most important point in setting up a secondary battery is to carefully insulate the cells from each other, and from any moisture. This is best effected by arranging them on wooden shelves raised about 8in. off the floor, and at an equal distance from the walls. The boxes should be left with a space of at least an inch between them, and wherever possible placed in single rows and not upon shelves one on the top of the other, so that free access may be had to each box. In large installations the cells are often of considerable size, weighing from 5 to 6 cwts. each, thus rendering it extremely difficult to move them. For these reasons they should be so arranged that, once

Digitized by Google

put up, they can be easily got at for repair without being removed. The importance of keeping the cells perfectly free from moisture can hardly be overrated. If they should be placed upon a damp floor, or in any position where moisture can get at them, there will be a considerable leakage of electricity, the cells will rapidly run down, *i.e.*, become discharged, and will be in all probability condemned as unworkable and useless.

All secondary batteries, when first set up, should be tested for insulation. This may easily be done by connecting one pole of the battery (after it has been charged) to one terminal of an ordinary galvanometer, and the other terminal of the galvanometer to earth. The best way to obtain a good earth is to connect the wire to a water or gas pipe; or if neither of these should be available, to drive a piece of iron into the ground and make a connection in that way. If the needle is deflected it indicates leakage, which should at once be remedied. The leakage will in all probability be found to arise from an escape of the solution from one of the cells, the place where they are standing being damp, or one of the leads "making earth." The poles of the cells should be connected together by stout bars of metal. It is inadvisable to use copper on the positive pole of a cell on account of the rapidity with which it corrodes. Plain lead connections or a mixture of lead and antimony are the most trustworthy. The positive pole of one cell is joined to the negative of the next, and so on all through the series. Then the positive pole of the dynamo is connected to the last positive of the battery, and the negative to the negative. The contacts must be properly made between each cell, as a bad contact will produce a great deal of heat in the cells, thereby introducing resistance into the circuit and reducing materially the rate of charge or discharge. Care should be taken not to charge the battery at too rapid a rate, and if at any time during the charging the cells become warm, the charging should be stopped, and the battery allowed to cool down. The heating of the plates causes them to buckle, often resulting in the short circuiting of the cell, and thus putting it out of use until the defect has been remedied.

During the charging, and also whilst they are at rest, it is advisable to test the cells from time to time. This may be readily done by taking a short length of stout wire, holding one end upon one pole of the cell to be tested, and striking the opposite pole with the other end of the wire. If the cell is in good condition it should give a bright crisp spark. If it gives no spark at all it shows that there is a short circuit in the cell, arising in all likelihood from two of the plates touching each other, or from a small piece of some conducting substance having fallen down between the plates. This should be at once remedied, otherwise the cell should be cut out from the circuit and taken to pieces. It is very important when working batteries to keep all the cells in as even a condition as possible. For if a cell be empty, or is discharged before the others, it will then become recharged in the reverse direction, and thus set up an opposing electromotive force to the rest of the battery; besides there is the risk of spoiling that particular cell. Keeping all the cells in the same condition is best effected by observing them when charging, and cutting out of the circuit all those cells that give off gas freely, and continuing to charge the others until they are all fully charged. If this is done about once in two months, the working efficiency of the battery will be maintained at a very high point. Of course this entails extra labour, but the author contends that secondary batteries do, and always will, require skilled supervision. Care must be taken not to cut out too many cells whilst charging the battery without introducing a corresponding resistance, or the dynamo will be burnt.

The ordinary strength of the electrolyte is 1 part of sul phuric acid to 9 parts of water, or of a specific gravity of 1·2, that of sulphuric acid being 1·84. The water should be as pure as possible. When working a battery, it is necessary to keep all the plates immersed in the electrolyte. If it becomes nccessary to add to the electrolyte, to keep the cell full water only should be used, otherwise the solution will become too strong. When batteries are left out of use for any length of time it is advisable either to remove the solution and wash the plates and boxes with water, or else to leave them fully charged. This latter method is, perhaps, best adopted only when the battery is not to be out of use for very long. It is found that when batteries are left idle and full of solution sulphate of lead will form all over the plates, and have a serious effect upon their future working.

By discharging a cell too rapidly, as much harm can be done to it as by charging it too rapidly.

The best dynamos for charging accumulators are shunt dynamos. Both the series and compound machines are liable to have their poles reversed by the batteries discharging through them, which is likely to arise from the speed of the dynamo decreasing, and thereby having its electromotive force overpowered by that of the battery. This difficulty might be overcome by specially-designed automatic switches. The most economical way is to charge each battery in two series in parallel, though, of course, whilst charging them in this manner, no lights can be run at the same time. The circuit should be so arranged that the dynamo is charging the battery in two series in parallel, or in one series with the lamps in parallel, or dynamo, lamps, and battery all in parallel. In order to charge an accumulator, it is necessary to employ a dynamo giving an electromotive force greater than that of the cells, and greater in proportion to the rate of charge required; but as all excess of electromotive force is lost energy, a slow charge is the most economical where time is of little moment.

The uses to which accumulators may be put are almost endless. They are serviceable for every application of the electric current. Lighting being at present the most in need of them, by employing an accumulator in any installation, the failure of the light should be rendered almost impossible. The chief causes of break-downs are the slipping, or breaking of belts, the heating of the bearings, or some trivial mishap with the engine which may be set right in a few minutes, but which is sufficient to plunge the place so lighted into darkness. Now, by employing accumulators, if the engine has to be stopped, the batteries immediately come into action, and should run the lights long enough for the necessary repairs to be effected. In nine cases out of ten, the failure of the electric light can be traced to some minor breakage or mishap that can be remedied in half an hour or even less; but, of however short duration, a total extinction of the lights must follow when working direct from the dynamo. Again, in almost all factories and workshops where steam-power is used, there is a surplus of from 2 to 4 H.P. This surplus, if employed to drive a small dynamo and to charge batteries all day, would be sufficient to run enough incandescent lamps to light up the whole of the shops in the evening. Accumulators may also be used advantageously in steadying the light when the dynamo is worked by a gas-engine, or any irregular source of power. The only method of satisfactorily solving the problem of the utilisation of water-power is by employing storage batteries, so that the water, instead of running to waste day and night, could be made to store electricity, which in its turn could either be used for motive power or for ordinary lighting purposes, and be drawn off at will. This applies also to the possibility of utilising wind power.

The employment of secondary batteries for driving trains, tramcars, boats, &c., has been a good deal discussed, but up to the present time, although many costly experiments have been undertaken, no practical work has been done.

The first experimental launch worked by accumulators was that fitted up by the Electrical Power Storage Company, and launched at Millwall in September, 1882. She was 25ft. long, 5ft. beam, with accommodation for about ten passengers. She was driven by two Siemens dynamos of the S D_3 type, coupled in parallel. The current was supplied by forty-five 1 horse-power Faure-Sellon-Volckmar cells. The two motors running together absorbed a current of 46 amperes, and developed about 3·75 horse-power. The weight of each motor was 316lb.; that of the countershaft, &c., was 180lb.; and the total weight of the accumulators was 2,520lb., or 56lb. per cell.

The second launch was built by Messrs. Yarrow and Co., of Poplar, and was fitted with all the electrical arrangements by the

Digitized by Google

Electrical Power Storage Company for the Vienna Exhibition of 1883. She is 40ft. long, 5ft. beam, and will carry about forty passengers. In this boat the motor and batteries are placed under the floor. The motor used is a Siemens D_2 dynamo, which with eighty Faure-Sellon-Volckmar accumulators (the number carried) will develop 7 horse-power. Its weight is 658lb., and the efficiency when tested was 78 per cent. In this boat no gearing is used between the motor and screw-shaft, the former being coupled directly to the latter. The average speed attained was eight miles per hour. The advantages are that whereas two men are necessary to work a steam launch, the electric launch needs but one man to look after it, as he can steer, stop, or regulate the speed at the same time. An electric launch will also carry more passengers, besides being free from smoke, smell, heat, and noise.

The experiments carried out with tramcars have not yet advanced nearly so far. A trial trip was made on the Gunnersbury and Kew tramway line on the 10th of March, 1883. The experimental car, as in the case of the launch, was fitted up by the Electrical Power Storage Company, and was of the ordinary type used upon the London tramways. It was driven by a Siemens dynamo, designed to work with an electromotive force of 100 volts, and a current of 60 amperes furnished by 50 accumulators placed under the seats of the car. The cells measured 13in. by 11in. by 7in., and weighed 80lb., their total weight being 4,000lb. The storage capacity of each cell was 560 ampere-hours. Apart from this experiment, which did not altogether end successfully, the problem of propelling tramcars has not been solved. The same company exhibited a tricycle at the Vienna Exhibition worked by 21 small accumulators, and a motor designed by Mr. Reckenzaun, of London. This would run for about one hour, and cover about eight miles in that time. The main reason why electricity has not yet been employed for motive power, for boats and tramcars, is, the author thinks, undoubtedly to be traced to the still imperfect and unsatisfactory state of secondary batteries. When once they have been so far improved as to be looked upon as trustworthy, a great and lasting impetus will certainly be given to the utilisation of electricity, for motive power as well as for lighting purposes.

ON THE CALCULATION OF MAINS FOR THE DISTRIBUTION OF ELECTRICITY.*

BY W. H. SNELL, ASSOCIATE.

In any scheme for supplying electric light upon any large scale the determination of the proper sectional area of the conductors is one of the most important problems that we have to solve. It is well understood that, no matter what may be the particular method of distribution which has been adopted, this sectional area must in every part of the system be made to conform as closely as possible to Sir W. Thomson's law of economy; and, therefore, the dimensions of the conductors should be so proportioned that the annual value of the work lost in heating the metal shall equal the annual charge for interest on first cost, maintenance, and depreciation, so far as this is proportionate to their sectional area. These results may possibly require some modification when, at a later stage, we determine (1) the rise of temperature in each section under maximum current, and (2) the distribution of potential throughout the system. But if these considerations demand any serious deviation from the economic standard, it will become a question whether we have selected the most efficient method of distribution.

Determination of Most Probable Value of "C" in the "Equation of Economy."

Now, in the equation of economy we have to make

$$P = P_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where P is the annual value of the heat wasted in the conductor, and P_1 is the annual charge for the cable. P is of the form

$$P = C^2 R K \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where R is the resistance of this section of the cable. K is some constant to be afterwards determined, and C must have a value such that a constant current equal to C would in one year produce the same total heat as does the variable and discontinuous current which is actually transmitted. It is evident that the true value of C will always be an unknown factor, but unless we can get some approximate idea of this value the equation of economy is useless and, indeed, misleading. It is therefore important to consider by what means we may arrive at as close an approximation as the nature of the case will permit. The problem is not in itself one of great simplicity, although it permits of being reduced to a set of quadratic equations.

We see at once that the actual current will vary with the time of the day, with the day of the week, and the period of the year, as well as to a certain extent in an entirely irregular manner; and the difficulty is considerably increased by the fact that the heat wasted in the cable varies, not as the current itself, but as its square. However, it seems probable that in practice we shall usually be able to assign limiting values of C with a fair degree of certainty; and if in any case these limits are too wide to be of much service, we can then, by a sufficient amount of labour, arrive at a still closer approximation. It must be confessed, however, that the method to be proposed for this second approximation is sufficiently clumsy and laborious, and it is very possible that something simpler or more accurate remains to be suggested.

It will be convenient to call the value of C, as above defined, "the mean annual thermal current," or, briefly, "the thermal current." In future we will write it C_θ. Put

$$\frac{C_\theta}{c} = N \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where c is the current required per lamp of normal candle-power; then N is the number of lamps which, if burning continuously all the year round, would cause the same heat waste in the conductor as that actually wasted by the whole of the lamps.

Now, it is also understood that theoretically the size of the conductors should be proportionately diminished as each branch or house wire is taken off, so that the number of amperes per square inch remains constant throughout the system. But it is important to notice that this tapering must not be determined by the actual number of lamps upon the wires, but by the corresponding value of N as just defined. *It is therefore necessary to determine the value of* N *for each section of the cable.* Of course in practice there will be a limit to the frequency with which the dimensions of the conductor can be (economically) adjusted. This limit will probably vary to some extent with the size of the conductors, but for the present we shall assume that the length of each section has been provisionally determined and marked upon the plan.

We may also observe, in passing, that the rule that the number of amperes per square inch of sectional area should be constant throughout the system, is based upon the assumption that the cost of insulation and maintenance bears a constant ratio to the sectional area of the conductor. This is by no means always the case.

Now, the heat generated in any section in any period during which the number of lamps burning is constant is proportionate to the square of the number of lamps supplied through that section, and to the length of the period. If the number of lamps alight varies from time to time, then the total heat generated during the whole period T is proportionate to

$$n_1^2 t_1 + n_2^2 t_2 + \ldots .$$

where t_1, t_2, &c., are the successive periods during which the number of lamps burning is respectively n_1, n_2, &c. Let t_1, t_2, &c., be in hours, and let T be the number of hours in one day, and put

$$n_1^2 t_1 + n_2^2 t_2 + \ldots = N^2 T,$$

so that

$$N = \sqrt{\left(\frac{n_1^2 t_1 + n_2^2 t_2 + \ldots}{T}\right)} \quad . \quad . \quad . \quad (4)$$

Then if for the present we assume that the respective values of n_1, n_2, &c., are constant day by day, N will have the same value as in equation (3), and will represent the number of

*Paper read before the Society of Telegraph-Engineers and Electricians.

Digitized by Google

lamps which, if burning continuously, would in twelve months generate the same waste heat as is actually generated.

Now, during the same period, if, as before, n_1, n_2, ... lamps burn for t_1, t_2, . . . hours respectively, the total number of lamp-hours per day is equal to

$$n_1 t_1 + n_2 t_2 + \ldots$$

Put this equal to M T, where M is the number of lamps which, if burning continuously, would give the same total number of lamp-hours per day.

Then we have

$$M = \frac{n_1 t_1 + n_2 t_2 + \ldots}{T} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

And if we also put $c\,M = C_t$, we may call C_t "the mean annual lighting current."

Comparing C_t with C_θ, or, more conveniently, M with N, we can easily see that when $n_1 = n_2 = \ldots$, and also $(t_1 + t_2 + \ldots) = T$, we shall have N = M. This is the case when the actual current is constant and continuous throughout the day; and inasmuch as the sum of the values of t can never be greater than T, it can be shown that N cannot be less than M. Therefore we have for the *minimum possible value* of N,

$$\text{(absolute min.)} \quad N = M \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

But, as we have just seen, this can only be a real value when the values of n_1, n_2, ... are constant and equal to each other, and the period of burning continuous.

As a matter of fact we know that the M T lamp hours are practically performed *within* some period of (say) t hours per day. Let the average number of lamps alight at any one time during these t hours be n, then we shall have

$$n = \frac{M\,T}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Thus the *practical minimum value* of N is given by the equation

$$N = \sqrt{\frac{n^2 t}{T}}, \text{ that is, from (7)}$$

$$\text{(practical min.)} \quad N = M\sqrt{\frac{T}{t}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Next, to obtain the maximum value of N, let the total number of lamps upon the section be μ, and let τ be the average number of hours each lamp is in use per day, so that we have

$$M\,T = n\,t = \mu\,\tau \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Then it is obvious that N will be at a maximum when μ lamps burn τ hours; that is, when

$$N = \mu\sqrt{\frac{\tau}{T}}, \text{ that is, from (9)}$$

$$\text{(max.)} \quad N = \sqrt{M\,\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Thus we have seen that N lies between the limits

$$N\,(\text{min.}) = M\sqrt{\frac{T}{t}} \text{ and } N\,(\text{max.}) = \sqrt{M\,\mu}.$$

In (8) t really represents the total number of hours during which current is supplied, so that under Board of Trade regulations we should have $t = T$ very nearly; but practically nearly all the work will be done within a very much shorter mean annual daily period—perhaps not exceeding six or seven hours—and we may with but little error reduce t in proportion. For instance, let m_1 lamps burn t_1 hours, and after this let m_2 lamps burn during t_2 hours per day, and let $m_2\ t_2$ be small compared with $m_1\ t_1$, then we may put

$$t = \frac{m_1 t_1 + m_2 t_2}{m_1} \quad . \quad . \quad . \quad . \quad . \quad (11)$$

If we use this value of t in (8), the small error thus introduced is in excess.

In illustration of these formulæ let us suppose that on a certain cable supplying 200 lamps a run of 1,000 lamp-hours has been made within a period of 24 hours. Then $M = \frac{1,000}{24} = 42$; that is, the light supplied will have been equal to that of 42 lamps burning continuously throughout the whole time; and the heat wasted in the cable will have been equal to that wasted when N lamps burn continuously throughout the whole time. Then we know that N lies between the limits

$$N = M = 42; \text{ and } N = \sqrt{M\mu} = \sqrt{(200 \times 42)} = 91;$$

that is, the minimum value occurs when 42 lamps burn 24 hours, and the maximum when 200 lamps burn five hours ($\tau = 5$); the heat wasted being thus the same as if 91 lamps had burnt during the whole 24 hours. Suppose, however, that we know further that the whole of the work was performed within some period less than eight hours, so that $t = 8$, then the minimum becomes

$$N = M\sqrt{\frac{T}{t}} = 42\sqrt{3} = 73.$$

Therefore N lies between 73 and 91.

We may suppose the actual case to have been as follows:—

200	lamps burnt	4 hours	= 800	lamp-hours.
150	,,	,, 1 hour	= 150	,,
50	,,	,, 1 ,,	= 50	,,
		Total	1,000	,,

$$\therefore N\sqrt{\left\{\frac{(200^2 \times 4) + (150^2) + (50^2)}{24}\right\}} = 88.$$

Thus we see that whenever we can obtain a value for M and for t we can at once assign the value of the thermal current within certain limits. And these limits become narrower as M increases towards the value of μ, and as t diminishes towards the value of τ.

Suppose, however, that these limits are found to be wider than is desirable to work from, we have a means of obtaining a closer approximation. For this purpose we will examine another method by which we may assign a pair of limiting values for N. Let the lamps upon a given cable be divided into two groups, and assume that our information has enabled us to calculate (directly) the values of the thermal current and of the lighting currents for each group. We have thus obtained the values of N_1, N_2, and of M_1, M_2, and we have to find N and M, *i.e.*, the numbers corresponding to each current for the whole of the lamps upon the cable taken together.

It is evident that as regards M we have simply to put

$$M = M_1 + M_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

But the value of N will largely depend upon the question whether the period of running for the two groups is contemporaneous (wholly or in part) or successive. In fact N lies between the limits

$$N\,(\text{min.}) = \sqrt{(N_1^2 + N_2^2)} \text{ and } N\,(\text{max.}) = (N_1 + N_2).$$

In order to show this, in equation (4) for the value of N we will put t_1, t_2, ... each equal to unity. We can clearly do this with but little error by taking the unit sufficiently small, and taking as many successive values of n as are required.

We shall then have the following equations:—

$$N_1 = \sqrt{\left(\frac{n_1^2 + n_2^2 + \ldots}{T}\right)} \quad . \quad . \quad (12a)$$

$$N_2 = \sqrt{\left(\frac{m_1^2 + m_2^2 + \ldots}{T}\right)} \quad . \quad . \quad (12b)$$

$$\text{and } N = \sqrt{\left\{\frac{(n_1 + m_1)^2 + (n_2 + m_2)^2 + \ldots}{T}\right\}} \quad . \quad . \quad (13)$$

From (12a) and (12b) we have

$$N_1^2\,T = (n_1^2 + n_2^2 + \ldots.) \text{ and } N_2^2\,T = (m_1^2 + m_2^2 + \ldots),$$

and from (13)

$$N^2\,T = \{(n_1^2 + n_2^2 + \ldots) + (m_1^2 + m_2^2 + \ldots) + 2\,(n_1\,m_1 + n_2\,m_2 + \ldots)\}$$

$$\therefore N = \sqrt{\left\{N_1^2 + N_2^2 + \frac{2}{T}(n_1\,m_1 + n_2\,m_2 + \ldots)\right\}} \quad . \quad . \quad (14)$$

In this expression for N put $\frac{2}{T}(n_1\,m_1 + n_2\,m_2 + \ldots) = A$.

Now when the two groups run *successively* it is clear that we shall have $A = o$, because in each of the pairs of coefficients one of the factors will vanish. This gives for the *minimum* value of N

$$N = \sqrt{(N_1^2 + N_2^2)} \quad . \quad . \quad . \quad . \quad . \quad (15)$$

Digitized by Google

But when the groups are run contemporaneously throughout A will have its maximum value (all the terms having positive values), and the expression upon the right-hand side of (14) becomes a complete square. This gives for the *maximum* value of N

$$N = (N_1 + N_2) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

We now proceed to compare these limiting values of N with those found by the former process, and to select the lower of the two maxima and the higher of the two minima to form our working limits.

The maxima are $(N_1 + N_2)$ (16) and $(\mu_1 + \mu_2)\sqrt{\frac{\tau}{T}}$, or, as it may be more conveniently written, $\sqrt{\{(\mu_1 + \mu_2)\ (M_1 + M_2)\}}$; these last expressions being obvious developments of (10). It is also obvious that, as the latter of these expressions represents the maximum *possible* value of N, the former cannot be greater than this. That it will usually be considerably less may be seen by taking the maximum value of $(N_1 + N_2)$, which will be $(\sqrt{M_1 \mu_1} + \sqrt{M_2 \mu_2})$, and putting this equal to the maximum possible value of N.

Then if

$$\sqrt{M_1 \mu_1} + \sqrt{M_2 \mu_2} = \sqrt{\{(\mu_1 + \mu_2)\ (M_1 + M_2)\}},$$

we must have $N_1 = \mu_1$ and $M_2 = \mu_2$; that is, all the lamps must burn all the day. It follows that the lower of the two maxima is given by $N = (N_1 + N_2)$.

Taking next the two minima, we have obtained for the general expression of the minimum value of N

$$N = M\sqrt{\frac{T}{t}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

and if the corresponding values of t for N_1 and N_2 be t_1 and t_2, we can write for the minimum

$$N = (M_1 + M_2)\sqrt{\frac{T}{t}} \quad . \quad . \quad . \quad . \quad (17)$$

provided, however, that we have also $t_1 = t_2 = t$. For the present we will assume that this is the case. We have for the second minimum

$$N = \sqrt{(N_1^2 + N_2^2)} \quad . \quad . \quad . \quad . \quad . \quad (15)$$

and we shall show that the former value (17) is always greater than the latter (15), except when either M_1 or $M_2 = o$, in which case they are equal.

It will be sufficient to show that the minimum value of $(M_1 + M_2)\sqrt{\frac{T}{t}}$ is greater than the maximum value of $\sqrt{(N_1^2 + N_2^2)}$. Now the latter expression is at a maximum when $N_1 = \sqrt{M_1 \mu_1}$, and also $N_2 = \sqrt{M_2 \mu_2}$. From this we get for the maximum $\sqrt{(N_1^2 + N_2^2)} = \sqrt{(M_1 \mu_1 + M_2 \mu_2)}$, and this last expression is at a maximum when $M_2 = \mu_1$ and $M_2 = \mu_2$; that is finally, under these conditions, maximum value of

$$\sqrt{(N_1^2 + N_2^2)} + \sqrt{(M_1^2 + M_2^2)} \quad . \quad . \quad . \quad . \quad (18)$$

Again, as t cannot be $> T$, the *least* value of $(M_1 + M_2)\sqrt{\frac{T}{t}}$ is obtained when $t = T$. Thus we have mimimum value of

$$(M_1 + M_2)\sqrt{\frac{T}{t}} = (M_1 + M_2) \quad . \quad . \quad . \quad (19)$$

Now we have always $(M_1 + M_2) > \sqrt{(M_1^2 = M_2)}$, unless either M_1 or $M_2 = 0$, in which case the expressions are equal. Thus we have proved that the higher of the two minimum values is that of equation (17). And therefore finally N lies between the limits

$$N\ (\text{min.}) = (M_1 + M_2)\sqrt{\frac{T}{t}} \text{ and } N\ (\text{max.} = (N_1 + N_2).$$

We have assumed hitherto (for the sake of simplicity) that $t_1 = t_2$. If this is not the case it will make no difference in the results just obtained, but we shall have to find the proper value for t in the minimum (17). For this purpose let t_2 be greater than t_1. From (7) we have

$$n = \frac{M_1 T}{t_1}; \text{ similarly put } m = \frac{M_2 T}{t_2}.$$

Then

$$N_1 = \sqrt{\frac{n_1^2 t_1}{T}}, \text{ and } N_2 = \sqrt{\frac{m_2 t_2}{T}};$$

$$\therefore N = \sqrt{\left\{\frac{(n+m)^2 t_1 + m^2 (t_2 - t_1)}{T}\right\}} \quad . \quad (19a)$$

and we have to find a value for t such that N is also equal to

$$\sqrt{\left\{\frac{(n+m)^2 t}{T}\right\}} = (n+m)\sqrt{\frac{t}{T}} = (M_1 + M_2)\sqrt{\frac{T}{t}}.$$

Equating (19a) with the second of these expressions it will be found that (when $t_1 < t_2$)

$$t = t_1 + \frac{m^2}{(n+m)^2}(t_2 - t_1) \quad . \quad . \quad . \quad . \quad . \quad (20)$$

From this it will be seen that if $m = n$

$$t = \frac{3 t_1 + t_2}{4} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

If m is large compared to n, we have $t = t_2$ nearly. If n is large compared to m, we have $t_1 = t$ nearly.

(To be continued.)

PHILADELPHIA ELECTRICAL EXHIBITION, 1884.*

REPORT OF EXAMINERS.—*Sections V. and VIII.—Electric Lamps.*

The original scheme of committee work divided observations of electric lamps among four different sections, known respectively as the sections on "Arc Lamps," "Carbons for Arc Lamps," "Incandescent Lamps," and "Photometric Measurements." As the membership of all these sections was the same, it was soon found that this subdivision entailed unnecessary work and needless discussion, and the four sections were therefore consolidated into a group, designated by the Executive Committee as Group B.† The work of this group covered the whole subject of measurements on electric lamps.

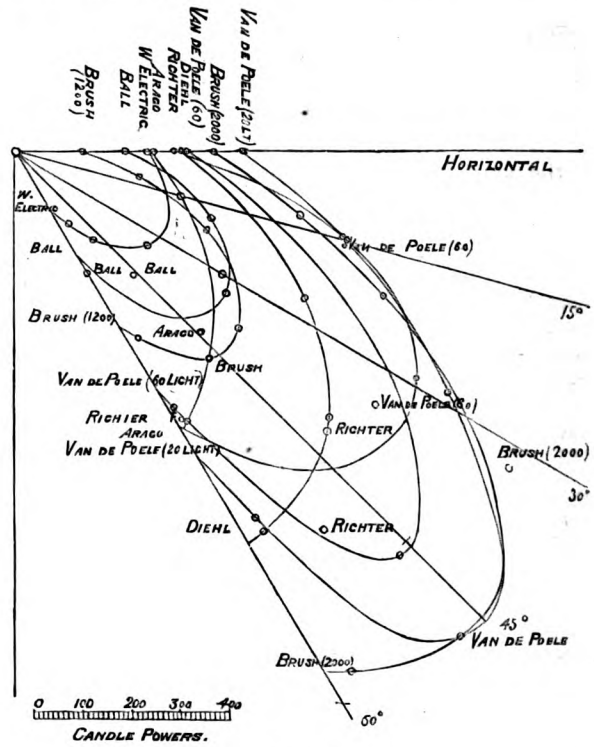

FIG. 1.

It having been long recognised that observations on incandescent lamps by which the *efficiency* only was ascertained were unsatisfactory, the desirability of observations to determine the *life* of lamps was obvious, and endeavours were made to organise such a test. The time required for such work prevented the committee from carrying it out, but the Executive Committee of the Exhibition having offered to arrange such a test the question was considered by the members of Group B, and it was voted that the tests of incandescent lamps should include *duration*, as well as *efficiency* measurements, and that such tests should be carried out under the direction of the Executive Committee of the Franklin Institute for the Exhibition. It was further voted that Group B should co-operate in such tests so far as was possible. A duration test was arranged by the Executive Committee, and invitations to take part therein were extended to the various incandescent lamp companies represented in the Exhibition. The work of Group B was therefore confined to observations of arc lamps.

The examinations of arc lamps consisted mainly in measurements of illuminating power of various angles, from a horizontal plane to sixty degrees below, and in measurements of current and potential at the terminals of the lamp. No attempt was made to examine critically the regu-

* From the *Journal* of the Franklin Institute for June, 1885.

† It was afterwards found advisable to present the report of Section VI. (Carbons) separately from the rest.

lating mechanism, or to measure the resistances of the regulating coils. The examinations were all conducted at the test house. Each lamp was supplied with current from the machine for which it was especially designed, and was adjusted and put in operation by the exhibitor, who also regulated the strength of the current.

Currents and potentials were measured by the same instruments employed in measurements of machines. The photometric apparatus and methods deserve a brief description. The standard to which all arc lights were referred was an Argand burner and Methven's screen, loaned to the committee by Mr. Wright, of Weston's laboratory, which was accompanied by a certificate from the maker to its exactness as a two-candle standard.

It was tested against two standard candles and found to give the same light and to be much more uniform. This standard was placed at one end of a photometer bar of 450cm. in length, at the other end of which was a 50 candle Swan lamp, serving as a secondary standard. This lamp was fed by a Brush storage battery, furnished and kept charged through the kindness of the representatives of the Brush Company. A second photometer bar making a small angle with the first, extended from this lamp into an adjoining room, where the arc lamp under test was suspended.

To permit of measurements of the light emitted from the arc lamp at various angles with the horizontal, the lamp was suspended from the end of an arm which was free to rotate about a horizontal axis parallel to the photometer bar, but vertically above it at such a height that when the arm was in a horizontal position the lamp could be suspended from its extremity with the arc on a level with the centre of the photometric disc. By this arrangement, when the end of the arm was raised the luminous point described a vertical circle whose axis was a line through the centre of the photometer disc and parallel to the bar. The raidus of this circle was 127 cm. and the distance of its plane from the secondary standard 640 cm. At the centre of this circle was placed a mirror of glass, silvered on the back, at such an angle that the light from the arc lamp falling upon it was reflected along the axis of the circle upon the photometer disc. It will be seen that the distance between the lamp and mirror was thus rendered constant for all elevations of the lamp, that when the mirror was adjusted to reflect the light upon the disc, the angles of incidence and reflection were always 45 deg., and that the distance from the image of the lamp to the secondary standard was always 767 cm. The mirror was carefully tested for absorption and the proper corrections made in the computation of the result.

The general plan of making observations was as follows: The arm from which the lamps were suspended was made horizontal and the height of the lamp adjusted to bring the luminous point on a level with the centre of the mirror and photometer disc. Two observers then adjusted and read the positions of the two discs ten times. The lamp was then raised by raising the end of the arm to which it was suspended and the readings repeated. This was continued until a sufficient number of positions had been taken.

Observations for current strength and for difference of potential between the binding posts of the lamp were made at frequent intervals while the photometric readings were in progress.

To facilitate the comparison of the arc lights with the standard, an apparatus was devised by which one-half or any larger fraction of the light could be cut off at pleasure. This apparatus consisted of a brass disc, about 30cm. in diameter, having 24 sector-shaped openings, all equal to each other and to the metal portions that remained between. Upon this was placed another exactly similar disc, which could be so turned as to close any desired fraction of the openings.

This apparatus was mounted on a spindle placed parallel to the photometer bar, and in such a position that the light from the arc lamp must pass through the openings to reach the photometer disc. When the apparatus was made to revolve at only a moderate rate of speed it was impossible to detect the slightest flicker or inequality in the light in consequence of its use.

In the tests made by your committee, the apparatus was used, when used at all, with the sectors full open, when it was assumed to cut off one half the light as theory would indicate.

Experiment showed that if there is any error in this assumption it is far less than those arising from the unsteadiness of arc lights.

Tables I. and II. embody the results of all the tests.

In Table I, column 1 gives the altitudes of the lamp at which the illuminating power was actually measured.

Column 2 gives the true candle-power for each altitude after applying all corrections. Each result given is a mean of ten observations.

Column 3, the mean of the observations for current.

Column 4, the mean of the observations for difference of potential between binding posts.

Column 5, the electrical energy consumed by the lamp in Watts.

Column 6, the same in horse-powers.

Column 7 gives the candle-powers for each 15 deg. of altitude from the horizontal to 60 deg., as deduced from the curves given in Fig. 1.

Column 9 gives the candles per horse-power for the same elevations.

Under the head of "Remarks" are given such observations as were made, during the progress of the tests, as to the working of the lamps.

Table II. has been compiled to exhibit the results of the observations as to the steadiness of the light. The several columns give the ratios between the arc light and the standard for each of the ten observations for each altitude.

Fig. 1, in p. 104, shows on a system of polar co-ordinates, the relative intensities of the various lamps tested, and the distribution of the light below a horizontal plane. The advantage of placing an arc lamp at a considerable elevation appears very clearly from an inspection of these curves.

TABLE II.—*Variations in Intensity of Lights while under Tests.*

* Indicates Mean, † Standard, ‡ Multiplier, ¶ Disc Multiplier, § Candles.

Note.—The multipliers in Table II. are those by which the intensity of the standard is to be multiplied to give the light of arc lamps, as observed. This product is to be multiplied by the constant 1·192, to allow for loss by reflection, and when the revolving disc was used by 2·. The final product is the intensity of the arc lights in candles.

The variation of the multipliers in any one column is therefore a measurement of the inconstancy of the arc light at that altitude. If the actual variations are desired in candles, each multiplier must be multiplied by the intensity of the standard, by 1·192 and when disc is used by 2·.

LEGAL.

The Lancashire Maxim-Weston Electric Co. v. The Maxim-Weston Electric Co.

This case was before Vice-Chancellor Sir James Bacon on the 12th inst. in the Chancery Division, when Mr. Marten, Q.C., moved on behalf of the plaintiff company, which is in voluntary liquidation, to have it declared that the defendant company were not entitled to a lien upon the plaintiffs' property for £10,000 in respect of unpaid purchase money due by the defendants to the plaintiffs. The Maxim Company was formed to work an electric light patent in Lancashire, and in December, 1882, they granted in consideration of the payment of £20,000 to them certain licenses in Lancashire, North Wales, and Cheshire to the plaintiffs, the Lancashire Maxim-Weston Electric Light Company. The purchase money was to be paid—£10,000 cash and £10,000 in shares. The plaintiff company had gone into voluntary liquidation, and the £10,000 cash was still unpaid. The defendants thereupon claimed to have a lien for the amount of unpaid purchase money over the plaintiffs' property, and also to be allowed to prove against them. Mr. Hemming, Q.C., appeared for the defendants.

The Vice-Chancellor decided that the defendants had no lien on the plaintiffs' property, but that they should prove in the liquidation for the amount due to them.

COMPANIES' MEETINGS & REPORTS.

The Hammond Electric Light and Power Supply Company (Limited).

An extraordinary general meting of this Company was held on Wednesday, at the Company's office, Appold-street, E.C., for the purpose of considering, and if deemed expedient, passing the subjoined extraordinary resolution, viz.:—"That it has been proved to the satisfaction of this meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same, and accordingly that the Company be wound up voluntarily." Mr. Robert Hammond presided.

The proceedings were private, but the following report has been furnished us by a shareholder. The following circular was taken as read:—

"To the shareholders of the Hammond Electric Light and Power Supply Company (Limited).

"Since the last ordinary general meeting the Board have used every effort to extend the use of the electric light, and early in this year they succeeded in obtaining from the Commissioners of Sewers of the Corporation of the City of London powers in reference to laying electric light mains, &c., in the City, without any of the restrictive clauses of the Electric Lighting Act, 1883. Notwithstanding this valuable concession, the Directors have failed to induce capitalists to subscribe the funds necessary for the starting of the large central station, and the carrying out the necessary work. At Brighton, Eastbourne, and Hastings, however, the Company have succeeded in setting on foot town systems, which will, no doubt, in the course of a few years, prove very remunerative. These installations have necessitated large outlays on plant, and a complete absorption of the Company's funds. But in the direction of isolated installations, the Company have entirely failed to obtain business of a paying nature, and in the carrying out of its operations it has had to keep up a very large and expensive staff, to pay standing charges upon works, royalties, &c., the ultimate result being that the Company finds itself unable, upon its present resources, to continue its business, or to meet its immediate cash liabilities. Under these circumstances, in view of the fact that the Directors see no reasonable probability of a demand arising at an early date for electrical apparatus in sufficient quantities to make the manufacture thereof a remunerative business, they have no alternative in the interests of all concerned, but to set on foot the necessary steps for liquidating the Company's affairs. The Directors also think it desirable to mention that, with their full concurrence, and with the support of the principal creditors, and to secure a favourable realisation of the Company's assets, Mr. Hammond has presented a petition to the Court of Chancery for the winding up of the Company. The Directors confidently believe that by a judicious liquidation of the Company's affairs, and freedom from pressure at the instance of creditors, the liquidator will be able to realise on favourable terms the large stock of Brush and Ferranti dynamos, lamps, and other electrical stock held by the Company, with the probability of an ultimate return to the shareholders, after paying all the creditors of the Company in full."

The CHAIRMAN said the very unpleasant duty devolved upon him of moving the resolution which had been read by the secretary. That resolution said that the Company could not, by reason of its liabilities, continue its business. The bare proof connected with that would take very little time, because it simply resolved itself into comparing the amount in the bank available to pay the debts with the amount the Company owed. According to the statement of affairs which he had before him, they had reduced their banker's balance to a matter of about £30, and there was out in the form of debts a sum of £1,916, which, with calls in arrear, and bills receivable, he found made only £2,100; whereas on the other side they had liabilities amounting to £15,000. A portion of that consisted of bills payable, which were falling due gradually from time to time, and trade creditors of £6,500; £5,000 which they raised on debentures, and £2,000 liabilities on contracts, which, of course, did not press. There was certainly £8,500 which ought to be met almost immediately, while on the other hand, if they collected the whole debts of the Company, they would only have £2,000 to meet that with. It would be an exceedingly unsatisfactory thing to content himself with that bald statement of debtor and creditor as far as the cash was concerned, because no doubt the shareholders would like to know something of the history of the Company since they last met, and something that would show how the assets of the Company had been employed during that time. The endeavour of the Company had been from the very beginning to press forward electric lighting in the best manner, and to do the very best for the Company. If the circumstances of a new industry had been against the Company, and if the legislation which had been set on foot had absolutely prevented the Company from going on, it had not been the fault of that Board. Speaking for himself and colleagues, he was able to say that from the beginning they had given this Company incessant attention. There were many persons who were greatly interested in the electric light, but it had some deadly enemies, who believed that every man connected with it was a thief.

A SHAREHOLDER asked why Sir Charles Young had resigned.

The CHAIRMAN replied that he was sorry to say that during the last year or two the health of Sir Charles Young had not been very good, and he had been strongly advised by his physicians to diminish his responsibility as much as possible. Sir Charles Young said that practically he (Mr. Hammond) was Chairman, and he would like him to preside at the next meeting. Sir Charles was now in the country getting rest, and he had sent a letter showing that his medical advisers urged him to go in the City as little as possible. The Directors had not drawn any fees since the last meeting. This was the closing meeting of the Company, because if they would not be wound up voluntarily it must be done compulsorily. The Directors were endeavouring to save what they could for the benefit of the Company. They were aware that the Company got from the City most valuable concessions for laying mains in the City of London. That was obtained by himself personally through very hard work. He got from the Commissioners of Sewers powers to lay mains in the City without limit of price for electricity, and no purchase clause. Under the Act of 1882 any undertaking was liable to be purchased at the option of the local authorities in 21 years; but he got an Act of Parliament without that limitation. He felt that while they had a chance of carrying that out it was very undesirable to call the shareholders together, and to put before them a balance-sheet, because he was endeavouring by every means in his power to raise money. He first went to the largest shareholders, and consulted them; but they said that they had lost money enough, and did not care to put any more into the concern. He thought until about a fortnight ago that he would be able to get the money. Everyone knew that they had borrowed £5,000 from their bankers, and they felt that they should not hold a meeting such as the one that was now being held until all hope of the City concession was given up. With regard to what the Company had been doing during its life, they must remember that when the Company was started to take over the business which he personally had set on foot, it was shown that the business he had been doing in the various large mills had been a very good one. The Company took over a good business, and the most unfortunate thing that happened to it was obtaining a Stock Exchange quotation. The very success of their Company brought a lot of competitors into the field. Their £2. 10s. shares actually went to £4, and the consequence was that a number of people about the country sprang up who were willing to put up isolated installations for practically nothing. As a private concern he was making £4,000 or £5,000 a year on a capital of £20,000, but as soon as they started as a company 20 or 30 companies were launched who were willing to put up installations merely as an advertisement. The fact was that the business was cut away from under them. It was true that they might have wound up a long time ago, but they felt that the electric lighting industry had an immense future before it, and they also knew that those who had had the light put up had been immensely delighted with it. They believed that electric lighting had as big a future before it as gas. The only thing that they could be blamed for was for waiting on hoping that the fruits would come to them which undoubtedly must come to their successors. At the time that it appeared that they would have a large amount of business they bought from the Brush Company a large amount of Brush plant and machinery. Their money was thus locked up, and Brush machines which cost £320 became only worth £150, and therefore they had had on that account to wipe off very heavy sums of money. They then saw that the great future for electric lighting was house to house installations, and that it was necessary to make a centre from which to supply electricity. They put a certain sum of money into the Eastbourne and Hastings installations in order to make them more successful. At Brighton they began in a shed; but they quickly extended that, and there was no doubt that the installation there, which at present was a loss, could soon be turned into a profit. It only required about £300 to complete their arrangements at Brighton, and then probably 10 or 15 per cent. would be returned on the capital laid out at that place. They had not only demonstrated as no other electric lighting company had done the possibility of house to house lighting, but they went to Parliament, and obtained permission for the lighting of Hampstead. They felt that if once they started house to house installations at Hampstead it would be an immense profit to them. They went to their shareholders and told them of this, and said that they wanted financial help; but their shareholders would not furnish them with a farthing. He did not complain of the shareholders thinking they were in electric lighting too early, and saying that they had lost money enough and would not throw away any more. After all the time he had spent over Hampstead they had to abandon the whole thing. And then in November the bankers of Lombard-street said they wanted to have their

Digitized by Google

places lighted by electricity, and it was some compliment to them that they selected this Company as the best fitted to carry out such an undertaking. He sent to the largest shareholders, and said that if they could carry that out they would be able to make all their dead assets live ones, and the plant, which stood at £20,000 to £24,000, might be made to realise that sum instead of being sold under the hammer for what it would fetch. Every shareholder gave him the same answer, that they had lost enough money by electric lighting, that they had been in it too soon, and did not care to put more money into it. Outsiders also said that it was a too risky thing. There was none who would risk £100 in it. He did everything he could to get the money but failed. In the installations they had made they had gone beyond their tether, hoping to realise sufficient to carry out a satisfactory business which would have put them in funds, and then the bankers would have come forward if it had been necessary. In presenting the petition he had done it in the interests of the shareholders, because if the matter had gone into the hands of the creditors they would have been actuated by only one motive, namely, to get 20s. in the pound. He thought it would be advisable that the liquidator should be one who had seen from the beginning the working of the Company. With regard to the £6,000 in dispute, and which was on deposit at the bank, in a recent action their counsel was offered a verdict, but he said that he should prefer to prove his case in order that there might be no appeal, and then the defendant came into court, and as his counsel and solicitor were not present, on payment of the costs of the day he got the Court to adjourn the case, so that that matter was not yet settled. In conclusion the Chairman moved the resolution to wind the Company up voluntarily.

Mr. INCE seconded the motion. He expressed his regret that it was necessary to take the course proposed, and said he felt great sympathy with Mr. Hammond, who had laboured very hard to make the Company a success. He gave them his assurance that Mr. Hammond had done all he could do in the interests of the shareholders. Up to the 11th of this month Mr. Hammond had been striving to get the money for the city lighting, and if he had succeeded they would not have been there to pass a resolution such as the one proposed. It would be seen now that if they had published a balance-sheet at the time the shareholders expected it they would have had no chance of raising £60,000 to £80,000 for the City lighting. He did not believe that there was enough business for any company to succeed in isolated installations, and he did not think that any success would be achieved until the public had confidence, and a large sum was put down, and electric lighting could be proceeded with on a large scale so as to be able to compete with gas.

Mr. REYNOLDS said that the Brush Company was very busy with isolated installations, and they had their machines in all parts of the country. It appeared that there was no hope for this Company unless some shareholders came forward and advanced money; but he would ask whether there was not any chance of amalgamating with the Brush Company? At any rate they might sell their Brush plant back to the Brush Company. He asked how much of that plant they held.

The CHAIRMAN replied about £10,000.

Mr. REYNOLDS said that the Brush Company would give more for it than it would fetch under the hammer.

The CHAIRMAN said that he had approached the Brush Company and had done all he could to get them to amalgamate but ineffectually. The fact was that to carry on the Hammond Company more capital would be required, and the Brush Company would not make a call on their shareholders for that purpose. With regard to selling their plant to the Brush Company, they were unable to do that, as that company had refused to buy it, saying that they were manufacturers of plant and not buyers of it.

Mr. REYNOLDS asked if there was any litigation beyond what the shareholders knew of.

The CHAIRMAN replied that there was not, beyond a few writs for small amounts.

After some further discussion the motion was put to the meeting and carried.

Mr. Theobald was appointed liquidator at a remuneration of 600 guineas; and a committee of three, with power to add to their number, was appointed to confer with him and to see if it would be possible to reconstitute the Company.

The proceedings then terminated.

West Coast of America Telegraph Company.

Report of the Directors to be presented at the eighth ordinary general meeting, to be held at the Cannon-street Hotel, on the 24th inst., at 3 p.m.:—

The accounts for the year ended 31st December last show the gross revenue to be £52,011. 10s. 7d., against the sum of £57,338. 12s. 1d. for the previous year, and leave a nett balance of profit, after paying debenture interest and all other charges, of £14,523. 15s. 6d.—a result which, all things considered, is as satisfactory as could have been looked for, and which has enabled the Directors to commence the regular payment of dividends to shareholders, and to place the Company, by the creation of the reserve fund, in a much stronger and more healthy financial condition. Hitherto dividend payments, after wiping off the enormous arrears in the Company's accounts, have been paid when and so soon as the finances of the Company warranted such payments, but it is now contemplated by the Board to equalise the dividends, so far as practicable, and to make them payable half-yearly. A sum of £12,000 was distributed in dividends in January last year, and a further sum of £6,000 was also distributed in July last year. After the payment of both these amounts, and after placing a sum of £10,000 to reserve, there remains, as will be seen, to the credit of the Company a sum of £3,349. 1s. 3d. Out of this sum, with the object of simplifying the accounts, and fixing each year's dividends on a precise basis, the Board recommend that a final dividend of two shillings per share be declared for last year, with a further interim dividend out of the nett income for the current half year of two shillings per share, making in all a dividend, at this time, of four shillings per share, or a total sum to be distributed of £6,000. The expenditure of the Company for the year shows variations, and in some cases an increase over the expenditure of last year. Wherever an increase is shown, as it is shown in the purchase of cable which has been paid for out of revenue, it need hardly be stated that such increase has been held to be necessary for the maintenance and development of the Company's property and business. The Directors' fees show an increase, and are seemingly large; but this is owing to the extra fees all coming into the present balance-sheet, and in this connection it may as well now be stated that in years past, besides assuming heavy personal responsibilities on behalf of the Company, the Directors have given daily and almost undivided attention to the business of the Company, and have taken for their remuneration only nominal fees of a trifling amount. Regarding the present position and prospects of the Company, the Board have to report that, notwithstanding the fact that in some parts of the coast trade is almost if not entirely suspended, whilst in other parts—if not over the entire coast—trade is, as a whole, in a worse condition than has ever been known, the Company's receipts have not been so far materially affected for the current year, and that the decrease does not amount to more than £1,100 or £1,200, against which it is hoped the next accounts will show a considerable set off in the shape of decreased expenditure. The deplorable internecine struggle on the coast has continued up to this with almost unabated force, but there would seem to be sign that it will soon draw towards its close from sheer exhaustion if from no other cause. The Port of Mollendo, which has been closed and sealed for years, and at which this Company has always kept up a costly but entirely unremunerative station, is to be opened for trade this month, and it is to be hoped that this incident may be regarded as a herald of the restoration of peace and of the revival of trade. The Company's repairing steamer has been kept, and is still kept in the highest state of efficiency, but the Board are pleased to say that so far this year there has been no need to call for her services. The electrical condition and general working of the Company's cables still leave nothing to be desired. The members of the Board retiring by rotation are Mr. Thomas Fielden Campbell and Mr. William Edward MacAndrew, both of whom being eligible offer themselves for re-election. The auditor, Mr J. Weise, of Messrs. Turquand, Youngs, and Co., retires, and is eligible for re-election.

NOTES.

ELECTRICITY AMONGST THE MORMONS.—The Salt Lake City Electric Light Company is paying a fair dividend.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 19th inst. amounted to £3,030.

FIRE ALARM APPARATUS.—Messrs. J. E. Spagnoletti and Crookes have just completed three sets of Spagnoletti's patent fire alarm apparatus for Her Majesty's Post Office.

BOOKS RECEIVED.—A paper on "Electric Lighting," read before the Convention of the National Association of British and Irish Millers, held at Glasgow on the 17th inst., by Mr. Hartnell.

NEW MANUFACTORY.—The creation is announced in Berlin of a large manufactory of electrical apparatus. The necessary funds have been furnished by a group of capitalists in Berlin and Hamburg.

THE CANADIAN TELEGRAPHS.—A telegraph line is about to be built between Moose Jaw and Woodhills, and another is being constructed between Edmonton and Peace Hills by the military authorities.

QUICK WORK.—The announcement of the result of the Derby race, on 3rd June, was transmitted by the Direct United States Cable Company to the Associated Press Office, New York, in exactly three seconds.

PRESENTATION.—The young women employed in the South Australian post and telegraph offices presented Mr. Todd, the Postmaster-General, on the occasion of his departure for Europe, with a travelling bag and fittings.

THE ELECTRIC LIGHT AT GROSVENOR HOUSE.—The Duchess of Westminster gave a dance at Grosvenor House on Thursday night, when the Rubens Room and Picture Gallery were thrown open and illuminated by the electric light for the first time.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 19th inst. were £2,480, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NEW CABLE.—The Exchange Telegraph Company is informed that it is in contemplation to establish cable communication between Auckland and Fiji. Our most distant colony will thus be connected with Great Britain by wire. The proposal is being warmly supported by the mercantile interests in Auckland.

THE PHYLLOXERA AND ELECTRICITY.—Spanish newspapers announce that the vines in several vineyards near Malaga, which have been abandoned as defunct, have shown evidence of vitality. The destruction of the insects is attributable to the electrical condition of the atmosphere consequent upon the recent earthquakes in Spain.

TOO GOOD TO BE TRUE!—The statement comes from Boston that an inventor there has produced an incandescent lamp which does not require a vacuum. The filament is said to be composed of a platinum wire covered over with a non-combustible material, which will expand and contract with the platinum wire, when heated, without cracking or peeling off.

PRESENTATIONS BY THE SHAH OF PERSIA.—The Shah of Persia has presented to Colonel Bateman-Champain, R.E., and to Lieut.-Colonel Murdoch Smith, R.E., two handsome swords of honour, in token of His Majesty's appreciation of the long services rendered by those officers in connection with the establishment and maintenance of the telegraphs in Persia.

THE ELECTRIC LIGHT FOR WAR SHIPS.—Messrs. R. E. Crompton and Co., of the Arc Electric Light Works, Chelmsford, have completed a projector for an ironclad in the Brazilian Navy, to be used for torpedo warfare. The lamp is of 25,000 candle-power, and with its assistance any object on the sea within a radius of three miles can be detected with great ease.

THE WATERLOO AND CHARING-CROSS ELECTRIC RAILWAY.—On Thursday afternoon the Bill (which has already been sanctioned by the House of Commons) for the abandonment of the authorised electric railway from the loop line of Waterloo Station to the Charing-cross end of Northumberland-avenue, passed unopposed before Lord Redesdale's Committee in the House of Lords.

FORGING A TELEGRAM.—On Wednesday last, at Leeds, Lilian Roberts, a student at Malton College, was remanded on a charge of forging a telegraphic message purporting to be from the Public Prosecutor at Leeds to the Imperial District Court of Justice at Bozen, Austria, authorising the liberation of Max Doring, a photographer of Leeds, who had been apprehended on a charge of felony.

THE BRITISH ASSOCIATION.—The Organising Committee of Section A of the British Association have arranged for the following discussions at the Aberdeen meeting:—(1) "On Kinetic Theories of Gases;" (2) "On Standards of White Light." It would be convenient if those wishing to take part in the discussion would send in their names before the meeting to the Recorder of Section A.

WHO IS HE?—An American contemporary says:—"Reichemberg's system of telegraphing and telephoning on the same wire simultaneously has, it is said, been tried with success between Madrid and Toledo." "Is civilisation a failure," or has our contemporary been misled by the striking similarity of sound between Reichemberg and Van Ryssel-berghe? Anyhow, it looks rather mixed.

LONG-DISTANCE TELEPHONY.—Two German post and telegraph officials, who lately went to Brussels in order to make themselves acquainted with the application of the Van Ryssel-berghe system to the telegraph lines of Belgium, have complimented the Belgian telegraph engineers on the practical arrangements which they made, and Herr Elsasser has given a lecture on the system, published *in extenso* in the *Electrotechnische Zeitschrift*.

COMPRESSED STEEL MAGNETS.—The French Société d'Encouragement has, in consequence of a favourable report by M. Carnot, awarded a platinum medal to M. Clemandot for his steel magnets, compressed to the extent of 15 per cent. of their original volume, and capable of sustaining twenty times their own weight, while retaining their magnetisation to a remarkable degree. The magnets are made of Allevard steel, by M. A. Piat, of Paris.

PROPOSED ELECTRIC LIGHTING AT ST. AUSTELL.—We learn that Mr. J. E. Veale, of North Hill, St. Austell, proposes to put up a central electric light station for the supply of current for 800 or 1,000 lamps throughout the town and immediate neighbourhood if a sufficient number of customers can be secured beforehand. His professional advisers are Mr. Latimer Clark and Mr. Gisbert Kapp, who have independently

Digitized by Google

reported on the scheme. Mr. T. M. Coom, of St. Austell, is the resident electrical engineer.

AN ELECTRIC SCALE.—A very important patent has just been assigned, says the *Western Manufacturer*, to an American inventor. It is for an electric scale, which automatically weighs and records consecutively the weights and numbers of objects weighed. This electric device can be attached to any scale, but is especially designed for railways to weigh trains of cars while in motion, and to record weights of same. On a 30 ton scale it will register within 25lb. of actual weight of car and contents, and will record the weights and consecutive numbers of cars weighed while they are passing over the scale at any rate of speed.

THE EASTERN TELEGRAPH COMPANY.—This company announce that, subject to the final audit, the accounts show, after placing £100,000 to reserve fund, a balance available for dividend sufficient to pay at the general meeting on 16th July next, the fixed dividend of 3s. per share less tax, being at the rate of 6 per cent. per annum, on the preference shares, and a final dividend of 2s. 6d. per share with a bonus of 1s. per share, both free of income tax, on the ordinary shares of the company, making with previous payments on account a total dividend of 6 per cent. on those shares for the year ending 31st March last.

TEMPORARY INSTALLATIONS.—At the annual dinner, held at Trinity House, at which the Prince of Wales, the Duke of Edinburgh, the Duke of Cambridge, &c., were present, the rooms were lit by the electric light, supplied by the Electrical Power Storage Company. The light gave so much satisfaction that the company was called upon to repeat it during the course of the following week.—At Mrs. O'Hagan's fancy dress ball a large number of photographs were taken by Mr. Vanderweyde by the electric light, for which one arc lamp, taking 60 amperes, was employed. This was worked for over six hours from E.P.S. cells.

THE TELEGRAPH TO MERV.—A Reuter's telegram dated Simla, June 20, says:—Intelligence has been received here that the Russian telegraph line has been completed to Sarakhs. This is probably the branch from Merv to Sarakhs mentioned in our last issue. The Russian papers say that, at the request of General Komaroff, Governor of the Transcaspian region, the Minister of War has recognised the urgency of immediately establishing a line of telegraph connecting Merv with Askabad. This line would pass by Annow, Babadoorma, Bougatchik, Artchigan, and Sarakhs. Its length will be 500 versts, and the expense about 100,000 roubles.

AN ELECTRIC SUBMARINE BOAT.—Experiments are shortly to be made in Russia, says an American contemporary, with an American submarine boat, which is to be driven by electricity. The boat is to be 28ft. long, and have a speed of 10 knots, and is stated to be capable of travelling for a distance of 15 knots under water. It is to be manned by two men only, the captain and an electrician. The captain's position will be at the stern, where the apparatus for steering the boat is placed. The ventilation will be effected by compressed air. The mines are to be towed, and, in case of the boat being pursued, they can be discharged by electricity so as to blow up the enemy.

ELECTRIC LIGHTING OF BELGIAN RAILWAY STATIONS.—On the 24th inst. the electric lighting of the Courtrai Station, by arc or incandescent lamps, was let by public contract. For the first installation the motive power will be provided, but for the second it must be supplied by the contractor. The State Railway Administration reserves the right of terminating the contract at the end of each year, according to conditions laid down in the specification. Several other stations are also to be electrically lighted before long, as well as parts of the repairing shops at Mons and Gent-Brugge. At the Schaerbeek station the iron columns for carrying the arc lamps are already fixed.

THE NATIONAL TELEPHONE COMPANY.—On the 23rd inst. the Dundee and District Telephonic Company, which has been in existence during the past four or five years, was merged in the National Telephone Company. At a meeting of the local company, held on the same date, it was agreed to sell their business, as at 30th June current, to the National Company for £8,500. It was mentioned that the local company had paid an average dividend of 9 per cent., and that the shareholders would get their capital returned, with a bonus of 40 per cent. The National Company have come under a stipulation that the maximum rate to be charged in Dundee will be the same as in Aberdeen—£10 per annum.

THE TELEPHONE AND FIRES.—Having regard to our remarks in the last issue of *The Electrician* on the subject of the fire at Whiteley's, the Exchange Telegraph Company write to inform us that the alarm given by the telephone enabled the Brigade to arrive at the spot (a distance of about two-thirds of a mile) in five minutes after the signal was sent. The same company's system is employed for the protection of the eastern half of the Inventions Exhibition, and was the means of signalling the first alarm of the recent outbreak at the Indian Museum; and, as Mr. Cunliffe Owen stated in his letter to the *Daily Telegraph* of the 13th inst., the whole of the Exhibition fire staff were at their posts with all their appliances within five minutes of the alarm being given.

NEW REGULATOR.—It is said that a new lamp regulator has been invented by Fein, of Stuttgart. The lower carbon is attached to a plunger, at the bottom of which a float in a liquid is forced upward by hydrostatic pressure. This force is sufficient to form good contact in a small arc lamp of his own design. The support of the lamp contains the float and the carbon; the upper contact is of copper, and is in the form of a wheel, connected to the negative binding post and the frame of the lamp through a short projecting arm and an upright; the carbon connects with the positive through a platinum sleeve, in which it slides. This lamp, with a current of six amperes and six to eight volts, gave, it is alleged, an incandescent light of forty normal candle-power.

THE LUMLEY INCANDESCENT SYSTEM.—In the Lumley incandescent lamp the filament has the shape of a cross. The substance from which this filament is made is a secret, and it is claimed that better results are obtained with it than from those heretofore employed. The lamps range from 10 to 300 candle-power. The dimensions of a Lumley 75 light dynamo machine which was lately in operation at the works in Brooklyn, are as follow:—Length of machine, 2ft. 9in.; height of machine, 1ft. 5in.; width of machine, 1ft. 5in.; length of armature, 9in.; resistance of armature, ·79 ohm; resistance of field, ·78 ohm; E.M.F., 45 volts; current, 75 amperes; number of revolutions per minute, 1,600. The 16-candle lamps have a resistance of 60 ohms, and consequently require three-fourths of an ampere to maintain them.

THE ELECTRIC LIGHT AS AN INSECT DESTROYER.—There is apparently no end to the uses of electricity, and seldom a day passes that some new virtue is not found in this wonderful agent of nature. The most recent discovery is the value of

Digitized by Google

the element as a destroyer of insects, and those "horrid thousand-leggers," which the ladies look upon with mortal terror, are exterminated with amazing rapidity by just turning the powerful rays of an electric light upon their ugly little bodies. People have noticed scores of dead centipedes lying on the ground in the vicinity of electric lights, and investigation has disclosed the fact that the rays prove fatal to them without their coming in contact with the flame. Centipedes thrive in dark places, seldom coming out of their coverings during daylight, but it is not known exactly whether it is the powerful ray of the electric light or the small amount of electric current which escapes by induction, which proves fatal to them. There are some insects and fishes which cannot live in the light, and it is thought that the electric rays may be too powerful for the centipedes.—*Electrical World.*

THE TELEPHONE IN CINTRA, PORTUGAL.—The two old Moorish edifices, Pena Castle and Royal Palace, in Cintra, Portugal, were recently telephonically connected by the Edison Gower-Bell Telephone Company of Europe. As all who have visited the favourite summer resort of Cintra are aware, the castle is built on the summit of precipitous rock mountains, ascent to which is impossible except by means of the circuitous pathway. The wire employed was No. 14 B.W.G. steel, jointed to a few yards of No. 8 on either side of the insulator. The first of the latter was fixed high up one of the "Champagne" chimneys of the Royal palace, from thence to the ruined Moorish castle, and from thence to the Pena Castle. Those who have visited Cintra can easily understand the enormous difficulties which would necessarily be encountered in passing the line wire over the thousands of trees which cover the intervening ground, and also on account of the dangerous nature of the rocks for any ascent other than by the beaten circuitous track. To overcome these difficulties a novel innovation in the passing of telephone wire was adopted by Mr. Alan Danvers, the company's engineer. Rockets, with thin cords attached, were fired over the rocks and trees, the line wire being then attached to the cord and pulled after it.

THE CYCLONE AT ADEN.—Mr. Chevallier, the Superintendent of the Eastern Telegraph Company's Station, at Aden, writing on the 7th inst., gives the following account of the severe cyclone which recently passed over that district. He says:—"Last Wednesday was a day that will be long remembered in Aden. It rained hard all Tuesday night, and the sea was rough. At 9:24 a.m. we lost Bombay, and called him for some time on both cables. We tested, and concluded Bombay had earthed for monsoon storm without telling us. The fearful cyclone raging here at the time perhaps gave colour to this, and both cables being down together we never doubted the accuracy of our results. The testing room was dark, and the error was doubtless due to mistaking the ratio of bridge; on further testing we found faults were close to Aden. The cyclone raged furiously nearly all day, the force of the wind was supposed to be 100 miles per hour. Our quarters, being built from the solid rock, were not shifted, but we suffered terribly from broken windows, 56 panes of glass were blown in, and the instrument room presented a desolate appearance, the tables being covered with *débris* of broken windows and the floor flooded. Hardly a kutcha bungalow is left standing in Aden, and the natives inform me that our new possession, "Sheikh Otthman," is completely destroyed."

THE EARTHQUAKES.—Information has been received at the Hague from Java that the state of Krakatoa was causing some anxiety. Towards the end of April subterranean sounds were heard in the neighbourhood day after day, and flames arose from the crater. The rocks which emerged from the sea during the last eruption suddenly disappeared. Official reports have now come in with respect to the recent earthquakes in Cashmere, concerning which the earlier reports were so conflicting. The loss of human life has been ascertained to amount to 3,081. Investigations are being made with a view to a fuller and more scientific report on the phenomenon. A Reuter's telegram from Simla on June 20 says:—"A further despatch from the British Resident in Cashmere states that shocks of earthquake still continue, and that altogether 2,700 persons have been killed in the district of Camraj. The town of Baramula was completely destroyed by a severe shock on the 17th inst. An officer of the Geological Survey Department has been sent to examine the district and report upon the extent of the disaster. Advices from Berne, Switzerland, on June 20, state that several severe shocks of earthquake have occurred in that vicinity. The vibrations were also felt at Geneva. It is stated from Tiflis that a severe earthquake has occurred in the Eastern Caucasus. The town of Sikuch is said to have been completely swallowed up. The loss of property is estimated at several million roubles.

THE DYNAMICABLES AT CHELMSFORD.—On Friday, the 19th, many of the members of the Dynamicables enjoyed a pleasant diversion from their ordinary method of meeting in a visit to Messrs. Crompton and Co.'s works at Chelmsford. In the early part of the day a number of the more active of the younger members of the Dynamicables met at Liverpool-street, and went to Chelmsford to try conclusions at cricket with the Arcadians, a club supported by the pupils of this establishment. Although the Dynamicables were beaten, sufficient good form was shown to prove that, with a little trouble, a very good, if not a very strong, eleven might be made up from among the members, and it was afterwards suggested at the dinner that a cricket club should be formed among the Dynamicables. We trust this suggestion will be carried out. The following are the scores of the respective sides:—For the Arcadians, Albright 48, Williams 11, Bright 4, Dymond 47, Foster 10, Bowling 10, Wilder 3, Sorrenson 1, Stevenson 0, Robinson 1, Scrutton 11, extras 22. Total, 168. For the Dynamicables, S. Rawson 47, Joel 0, Sharp 4, Mountain 6, Defries 28, Crompton 0, Biggs 9, Ferranti 3, Kyle 4, Ram 1, Rawson 0, extras 7. Total, 109. The Dynamicables were entertained at luncheon by their victorious adversaries. Meanwhile other members of the society had gone to Chelmsford in order to inspect the very extensive works of Messrs Crompton and Co. The suggestion of paying such visits is a good one, and great interest was shown by the members of the society. The inspection of the works being finished, the members dined together at the Saracen's Head, and after a very enjoyable day returned to town.

SEPARATION OF ORE BY ELECTRICITY—A PROBLEM.—According to a contemporary, "the invention of a Swedish engineer, Herr Wenstrom, a machine for separating iron ore, is attracting considerable attention in Sweden. It consists of a hollow cylinder rotating horizontally, *with cog wheels at the ends, by which it is set in motion. In the centre of the cylinder is a kind of drum of iron bars, below which an electric battery is placed, which always remains stationary, and is set in motion by a dynamo machine and wire, having the effect of making the iron drum highly magnetic.* As the cylinder rotates iron ores are fed over the same, and which adhere to the cylinder when under the influence of the battery, but fall to the ground as soon as this—on the reverse side—ceases to attract. The machine is so constructed that it separates the ore into three

Digitized by Google

heaps, according to their richness. The feeding of the machine has to be done very carefully, and only crushed ore can be separated. The power required is very small, and the revolutions of the cylinder are twelve strokes per minute. Successful experiments have recently been made with the machine at the Koping Engineering Works." We fail to see anything very novel in this process, but the description of its construction as given by our contemporary certainly affords food for thought, and opens out a wide field for speculative reasoning. We have italicised the problematic paragraph for the benefit of our younger readers, who can exercise their ingenuity in determining the precise functions of cog wheels considered as motors, and also in deciding whether it is the drum or the battery which always remains stationary ; whether, in that case, they can be set in motion by a wire and a dynamo ; and, if so, what kind of a battery is it—primary, secondary, tertiary, or what—that necessitates, when the power required is very small, a dynamo and a wire to set it in motion? Perhaps, however, it is the drum. Think it out, will you ?

THE ELECTRIC LIGHT IN PERU.—A prominent merchant of Callao, Peru, is now in Boston on an important mission—the lighting of the great cities of that country with electricity. This gentleman says that many great improvements have been made in the country since he went there ; but, judging from past appearances, the near future will see many more public improvements, perhaps the most modern of which is the introduction of the electric light to the eight principal cities of the country—Lima, Callao, Arequipa, Puno, Cuzco, Trujillo, Cajamarca, and Puira. These cities, or many of them, are lighted at night with antiquated oil lamps, while others are illumined with the densest kind of yellow gas but little better than the oil lamps. This is a consequence of the high price of coal in these places. But water often takes the place of steam, and so it is intended in Peru. Some of these cities, Lima for instance, have ample water supplies for the purpose of running the electric machinery, and this will be duly economised, while in the other cities the light will be greatly improved at but little extra cost. Mr. Widlund and Mr. Macario Llaguno having been granted by the government the exclusive right of introducing electric lighting into the above eight cities for the next twenty years, they went to America to inquire as to the best system to adopt. Mr. Widlund made careful inquiry, and became satisfied that for their purposes the Thomson-Houston light was the best. The Peruvian Electrical Construction and Supply Company was then formed by gentlemen in the neighbourhood of Boston for supplying electric apparatus of the Thomson-Houston class to Peru. The works of the company at Lynn are now busily engaged in preparing the plant of ninety arc lights, with dynamos and boilers complete, for Lima, which is hoped will soon be ready for shipment, to be followed at short intervals by those for the other cities. In all cases iron lamp-posts will be used. The whole of the material for this lighting will go from New England. Mr. Widlund states that the price of gas in Lima is now 3.20 dollars per thousand, and then it is a poor light. The new company, by the terms made with Messrs. Widlund and Llaguno, will be allowed to import all the necessary apparatus free of duty, instead of paying 45 per cent., the usual impost, even the present gas company having to pay that on every lamp it erects.

THE "CASSEL" PROCESS FOR THE TREATMENT OF REFRACTORY GOLD ORES.—This process, which is purely one of chlorination by electricity, seems to bear promise of more satisfactory results than have hitherto been arrived at. The apparatus consists of a drum containing the anodes, formed of very dense carbon rods connected in multiple arc, and an iron vat which constitutes the cathode. Around the circumference of the drum strong asbestos cloth is arranged for the purpose of preventing the ores from reaching the cathode and acting as a filter. Common salt solution, or sea-water and lime, are the only substances used. The gold dissolved by the chlorine is carried by the current to the negative pole into the vat, and is deposited there as a black slime in the metallic form, from whence it can be scraped off and melted. The drum is revolved at the rate of about eight revolutions per minute, so that the ores may be constantly thrown against the anodes, whereby all the particles of gold are brought into most intimate contact with the pole, where the nascent chlorine is generated, and are readily converted into chloride of gold. The chemical action which takes place will be easily understood. Instead of the free gas being separately generated in the ordinary way, the chlorine is evolved in the apparatus in the *nascent* state in contact with the ores, in which condition it has an immensely greater combining capacity for gold. At the same time nascent oxygen is also generated which, oxydising the sulphides, arsenides, &c., liberates the gold, the nascent chloride at once converting it into a terchloride. A secondary reaction then takes place, and hypochlorous acid is formed, which oxydises the pyrites ; hydrochloric acid is also formed, which attacks any iron that may be present, forming a protosalt of that metal. This soluble iron compound precipitates the gold as fast as the chlorine brings it into solution, and thus prevents its extraction. Each drum has a resistance of about 0·3 ohm, the ends of the carbons being coppered, and, as before mentioned, mounted in multiple arc. A current of from 250 to 300 amperes is used. One drum will, we are informed, treat about half a ton of concentrates in 4 hours, or from 2½ to 3 tons in 24 hours. Where a number of drums are used the cathodes (iron tanks) are also connected in multiple arc. The current is supplied by an Oppermann dynamo and a small Elwell-Parker, giving approximately 17,000 watts in all. These, together with the drums and accessory machines, are driven by a 16 horse-power Otto gas engine.

THE EDISON-SWAN LAW SUIT IN GERMANY.—Our contemporary, the *Elektrotechnische Zeitschrift*, seems to be a convenient medium for the circulation of advertisements amongst the members of the society whose organ it is. Its last number contains a fly leaf issued by Mr. C. H. Stearn, the managing director of the Swan United Company, in which the exact legal position and the future policy of the company are thus defined. "The decision obtained by the Edison Company on the 9th of April was to the effect that Messrs. Nagle Brothers should be restrained from working or selling lamps manufactured under Swan's patent, No. 13,071, and it follows, therefore, first, that this verdict only concerns the firm mentioned, but no other parties ; and, secondly, that it only concerns lamps manufactured according to patent, No. 13,071. An appeal has been made, and there are good reasons for believing that the decision will be reversed. Moreover, our present lamps are manufactured only in part under patent No. 13,071, and in other parts under other and totally independent patents. We are therefore convinced that our present lamps do not infringe the Edison patent. We have entered a protest against the validity of this patent in the Supreme Court at Leipzig, and even if the patent should not fall altogether it will be restricted within the limits already assigned to it by the *Patentamt*, and thus the tendency of the Edison Company to establish a monopoly will be checked once for all. We have recently established, in Kalk-on-the-Rhine, that is on German soil, works for the manufacture of our lamps, and we are about to introduce further improvements, which

Digitized by Google

will make our lamps absolutely independent of the Edison patent. These new lamps we hope to put on the market within a few months. Inasmuch as the present lawsuits will probably last one or two years, it may be expected that by the time the final decision has been obtained all the present lamps will have been replaced in the natural order of things by our new pattern, but we undertake to replace all the old lamps which might then still be in use if the final decision should fail to upset the present verdict." We cannot but admire the pluck shown by the Swan United Company, and hope they will succeed in breaking down a monopoly which threatens to become a serious obstacle to the development of the electric lighting industry in Germany. It would almost seem as if the company's German connections had instilled into them something of Prince Bismarck's political creed: First tell the world, and your enemies especially, exactly what you mean to do, and secondly, do it.

THE INSTALLATION AT THE THEATRE ROYAL, MADRID.—The following is the result of some experiments conducted by Señor Isidoro Cabanyes with eight series of 50 accumulators each, supplying the current to the 250 incandescent lamps at the Theatre Royal, Madrid :—

$$\text{Per cell} \begin{cases} \text{E.M.F.} = 2{\cdot}35 \text{ volts.} \\ R_i = 0{\cdot}01 \text{ ohm.} \\ \text{Capacity} = 400{,}000 \text{ coulombs.} \end{cases}$$

$$\text{Lamp} \begin{cases} 100 \text{ volts.} \\ 0{\cdot}8 \text{ amperes.} \\ 125 \text{ ohms.} \end{cases} \qquad \text{Battery} \begin{cases} \text{E.M.F.} = 117{\cdot}5 \\ R_i = 0{\cdot}0625 \end{cases}$$

$$\text{Resistance of 250 lamps} = \frac{125}{250} = 0{\cdot}5$$

$$\text{Sum of resistances} = 0{\cdot}5625.$$

$$C = \frac{117{\cdot}5}{0{\cdot}5625 + a} = 250 \times 0{\cdot}8 = 200.$$

$$a = \frac{117{\cdot}5 - 112{\cdot}50}{200} = \frac{5}{200} = 0{\cdot}025.$$

$$T = \frac{g\,k\,.\,(f \times R + n \times R^1)}{f \times n^2}$$

T = time in seconds.
g = acceleration.
k = work (kgms.) of each cell
R = internal resistance of one cell.
n = number of series.
R^1 = resistance of exterior circuit.
E = E.M.F. of each cell.

Applying this formula to an actual case,

$$T = \frac{940{,}000\,.\,(0{\cdot}5 + 8 \times 0{\cdot}525)}{50 \times 5{\cdot}5225}$$

$$= \frac{4{,}418{,}000{,}000}{276{,}125} = 16{,}007'' = 4^h - 27'.$$

The charging of the accumulators was carried out as follows :—The cells were in 4 batteries, each battery being of 4 series of 25 elements, and these were charged in each case by a Gramme dynamo, type A, which, at 850 revolutions per minute, gave a current of 17 to 22 amperes, with a difference of potential at the terminals of 70 to 80 volts, and had an internal resistance of 1·5 ohm. The batteries were made up, as before observed, of 4 series of 25 elements :—

$$\begin{cases} \text{E.M.F.} = 58{\cdot}75 \\ R_i = 0{\cdot}0625 \\ R. = 3{\cdot}00 \\ \qquad \text{additional.} \end{cases}$$

This latter resistance was added for the reason that the best conditions were found when the exterior resistance was nearly double that of the interior.

$$T'' = \frac{g.\,K\,N}{t''.e.c''(1-m)} = \frac{94000000}{58{\cdot}75 \times 22 \times 0{\cdot}9}$$

$$= 80825'' = 22h - 27' \text{ during 24 hours.}$$

The dynamo under these conditions consumed very nearly 3 horse-power. The four dynamos with the respective batteries consumed about 12 horse-power. The total consumption then was $12 \times 24 = 288$ horse-power per hour, equivalent to about 14 steam horse-power during each period of 20 hours.

THE EVOLUTIONARY SQUADRON.—The correspondent of the *Standard* says :—"Bad weather and great darkness will materially assist the enemy, unless Admiral Whyte should decide to remove some of his ships into positions from which their electric lights can sweep the booms and the mine fields beyond. Yet, if the tops of the hills on Bere Island are properly occupied by the defenders, it ought to be difficult for the foe to approach either entrance to the anchorage without betraying themselves. In such circumstances as these in which we find ourselves, portable electric lighting apparatus would be particularly valuable. With good lamps on two or three eminences we might render it impossible for an enemy to surprise us from the sea. At the same time, it would not be easy to transport engines and dynamos to the craggy tops of these desolate hills; and, therefore, it is surely desirable that some means should be devised for the laying of wires from ships lying at an anchorage to points which it might be useful to illuminate. In this manner the existing engines afloat might be utilised in the conduct of operations on shore. On Tuesday various experiments were tried with the object of testing the electric contact mines that form a considerable part of the outer line of defence; and the "Mariner" crossed and recrossed the sections of submarine cylinders laid down by the "Minotaur," "Sultan," "Hercules," "Iron Duke," "Repulse," "Devastation," "Hotspur," "Lord Warden," and "Shannon." No charges were fired, but Menotti instruments were used that gave indication whenever a wire was struck. Only in two cases did these submarine engines fail, and then it was probably because the "Mariner's" draught of water (12ft. only) was too little to disturb them, they being laid at 10ft. below low-water level, and it was about half-tide when the experiment was tried." *The Times* correspondent, writing on the 24th inst., says: "Last night the ships used their electric lights, and the display was very striking. The brilliancy of the beams thrown from the different ships varied very much. Those produced by the old-fashioned Wilde machine were poor indeed when compared with the pencils of the D Grammes. It was noticeable how glaringly conspicuous the three ships which have been painted white, with a view to future service in the tropics, became under the light. One lesson of great practical importance has been taught us already by this assemblage of ships, and that is the absolute necessity that every squadron on active service should possess a Hecla, and, therefore, that a sufficient number of new Heclas should be ordered at once. Whether they ought to carry guns or not, or what alterations or improvements may be made so as to render them more efficient, is a matter of detail; the one important thing is that they should have a liberally-furnished factory capable of executing repairs to torpedoes, boats, engines, and electric light machines. Admiral Hornby is, wisely, extremely reticent as to his intentions, but it was generally understood that the grand attack was to take place to-morrow night. The "Hotspur" is to go outside as a sort of forlorn hope, prepared to sacrifice herself, and endeavour to decoy the enemy into the dangerous neighbourhood of mines that her own superior knowledge will enable her to avoid. She will carry a fixed electric light and be protected by nets. The gunboats also will have both nets and electric lights. The "Mariner" and "Racer" sloops will be considered neutral, but will exhibit electric lights."

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(*Continued from page 59.*)

The problem of the transmission of power by means of harmonic currents admits of being readily treated by the geometrical method, in the same fashion as local condensers and induction problems, and as, moreover, some interesting particulars are rendered so plain by the use of geometry as almost to be self-evident, that method will be here adopted.

To give a preliminary notion of the possibility of such an action, imagine an ordinary galvanometer subjected to alternating currents. The impulses on the needle considered as fixed would be as often and as strongly in one direction as in the other. But suppose that after an impulse in one direction the second and contrary impulse is not given *until the needle has passed over the dead point position*, which will be at right angles to the coils. In this case the second impulse will only add to the speed of the needle's rotation. Postpone the third impulse similarly until the second dead point has been passed, and again there will be positive acceleration. This elementary form of the problem enables the possibility of the motion to be conceived. But it does more than this, it shows that the direction of motion of the *receiving* machine is indeterminate. The impulse must be one which tends to throw the poles of the needle to the side of the coils remote from that on which they are when they receive the impulse; but the direction of rotation produced by the impulse simply depends upon which side of the dead point the needle may happen to be. Electric transmission of powers admits, therefore, of the following classification:—

A magneto machine giving a direct current and employed as a driver gives a current varying with its direction.

A similar magneto machine used as a follower takes a direction varying with that of the current.

A dynamo electric machine giving a direct current and used as a driver gives a current whose direction is indeterminate.

A dynamo electric machine used as a follower takes a direction determinate and independent of that of the current.

An alternating machine, whether used as a driver or a follower, may run in either direction indifferently. The period of the follower coincides with that of the driver.

To treat the question more generally and exactly, it must be remembered that in a simple circuit, possessing no capacity, and subject to sources of alternating electromotive force of the same period, we may combine all the electromotive forces into one having that period. Thus if A B, B C, C D, D E, E F, are a number of lines representing in magnitude and phase the various electromotive forces, and A F be joined, then A F is the single electromotive force which will produce the effects observed. If there exist self-induction or mutual induction the diagram can be completed in the manner already indicated in earlier articles, using A F as the single impressed E.M.F. We shall thus obtain a line representing the effective E.M.F., which will be in the same phase as the current. Dividing this by the resistance we can compute the current, and if we multiply the result by the projection upon this line of the line representing any of the individual component electromotive forces, and divide by 2 we shall obtain a measure of the power at work in the particular corresponding source. Now the projection of any individual line will be positive if the angle between it and the line of effective E.M.F. be less than a right angle, and negative if this angle be greater than a right angle.

In the former case the power is positive and the source does work.

In the second case the power is negative, and the source has work done upon it.

Thus in Fig. 14, let A B, B C, C D be the electromotive forces of these sources, laid down in their respective phases. Then A D is the resultant E.M.F.

The angle E D A has its tangent equal to $\frac{L\pi}{TR}$.

Where L is the coefficient of self-induction of the circuit,
R is the resistance,
and T is the half period of the undulation.

A E is at right angles to D E.

From C and B, C C′, B B′ are drawn perpendicular to E D.

The power exerted by source of A B is therefore $\frac{ED}{2R} . EB'$; similarly the power exerted by source of C D is $\frac{ED}{2R} . C'D$.

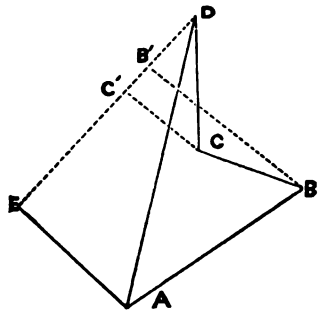

Fig. 14.

But the power of the source of B C is seen in the diagram to be negative. Hence this source has work done upon it with a power equal to $\frac{ED}{2R} . C'B'$.

Such a source would constitute what is called a motor; *i.e.*, it may be loaded in the mechanical sense of the word, and made to do work.

It will be seen that had the coefficient of self-induction been small, and E nearly coincided with A, the projection of B C upon E D would have been positive, and the source of B C would not have been a *recipient* source, but would have had to do part of the work of heating the circuit.

Having settled these preliminary ideas, let us suppose a case where the sources are two in number, represented in magnitude and phase by A B, B C (Fig. 15), of which B C is the smaller; and let A B C be less than $\frac{\pi}{2}$ in the direction of advancement.

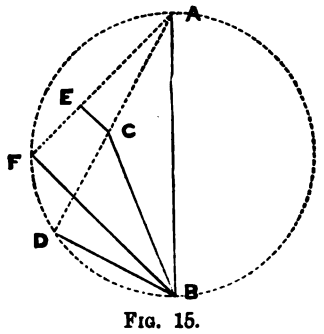

Fig. 15.

Upon A B as diameter describe a circle, and join A C and produce it to cut the circle in D.

From C A in the direction of retardation set off the angle C A F, having a tangent equal to $\frac{L\pi}{TR}$, the line A F cutting the circle in F.

L T and R have the usual significations.

Draw C E perpindicular to A F.

Join B D, B F, which lines will be at right angles to A D, A F, respectively.

Then, calling for brevity the source of A B the source A, and the source of B C the source C, we have

$$\text{The power exerted by Source A} = \frac{AE . AF}{2R}$$

$$\text{The power doing work on Source C} = \frac{AE . FE}{2R}$$

Thus work will be done upon C so long as E lies within the semicircle A F B, upon which F always lies. But if the

Digitized by Google

coefficient of self-induction is sufficiently increased the angle D A F will open out, and F will move along the circle towards A until F C B are in one straight line. This condition obtains when L is large enough to satisfy the equation,

$$\frac{L\pi}{TR}\sin\theta = \cos\theta - \frac{f}{e},$$

where θ is the angle A B C, and A B = e, B C = f.

If B C is so great that the point C approaches the circumference, C will for that reason alone cease to be a recipient source, for the projection of B C upon the line of effective E.M.F. will either vanish, if the coefficient of self-induction is evanescent, or be positive if this latter has a finite value, in which case the source C does work.

But suppose that matters are represented actually by Fig. 15, in which the source C is, suppose, loaded to the extent represented by $\frac{FE.EA}{2R}$. There will be a condition of equilibrium, but it is necessary to show that such a position will represent *stable* equilibrium; that is to say, it is necessary for

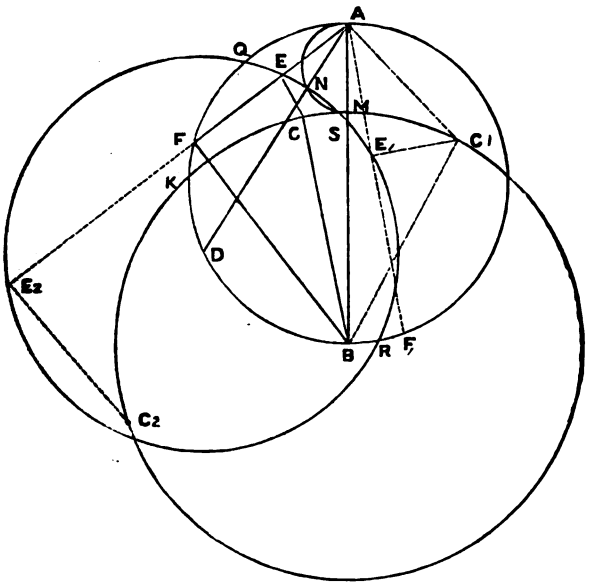

Fig. 16.

steady motion that, if the angle of phase difference C B A be slightly varied, there shall be a restitution of the exact position and not an augmentation of the displacement.

For the consideration of this point we may suppose the phase difference to be the only variable element, the two electromotive forces and the coefficient of self-induction remaining constant.

With a variation of the angle A B C, C evidently describes a circle round B as centre. Now A E always bears the same relation to A C, viz., the cosine of the angle E A C, which remains always the same, since the coefficient of self-induction does so. Therefore, whatever curve C describes round A, E will describe an exactly similar one on a scale diminished as the cosine of the angle E A C.

The curve which E describes will therefore be a circle whose radius is equal to C B cos E A C.

The two circles described by C and E will not, however, be similarly situated with regard to A B, but since E A makes a constant angle with C A, the circle described by E will be displaced in the direction of retardation by the amount of the angle E A C, at the same time that it is diminished, and drawn nearer to A in the proportion of the cosine of this angle.

We thus arrive at the following construction for Fig. 16. A B is the electromotive force of the driving machine. B M is cut off from A B, so that B M represents the electromotive force of the follower in *magnitude* only. M C K is a circle described with B M as radius. B D K is a circle described on A B as diameter. B A D is the angle whose tangent is equal to $\frac{L\pi}{TR}$, and is set off from B A in the direction of retardation. M N A is a circle described upon A M as diameter, and cutting A D in N. S N E Q is a circle described with centre D and radius D N, cutting the circle D B K in Q, and M B in S. Then, since A N : A M :: N D : M B :: cosine D A B : 1, and tan B A D = $\frac{L\pi}{TR}$, from the foregoing considerations the circle S N E Q is the circle described by the point E of Fig. 15.

Now, let B C be some particular position of the E.M.F. of the follower, and E the corresponding point upon the circle whose centre is D.

A E produced cuts the circle B D A in F.

Then the following proportion holds good.

The power exerted by A : power transmitted to C : power expended in circuit :: A F : F E : E A.

Now, suppose a displacement of B C to take place which diminishes the angle A B C—*i.e.*, C is displaced towards M, then evidently E is displaced also towards S; but F is displaced from Q, and therefore A F and F E both become larger.

But A F is proportional to the power exerted by the driver, therefore a greater load is thrown upon the prime mover, and A B will be displaced in the direction of retardation; *i.e.*, the angle C B A will tend to open out again for this reason.

But, further, the power transmitted to C is proportional to F E, and this is increased. The load on C being fixed, and the power being now more than is necessary, the source C will race. Hence, for this reason also, the angle A B C will open out, and regain its original size.

Now, suppose that C is displaced in the direction away from M, which would be the same thing as supposing a retardation of the driver.

In this case A F and F E would both become smaller. Therefore, the prime mover would race, and so A B would advance to close the angle A B C. The source C would have its power cut off, and the load remaining the same B C would be retarded, and again the angle C B A diminished.

Hence such a position would be one of stable equilibrium of the motion.

A position of equilibrium could also exist on the other side of S, as at E_1, C_1 and F_1 being the corresponding positions taken up by C and F respectively, but the equilibrium will be generally unstable.

For let C_1 and E_1 be displaced from M and S, implying a retardation of the follower. The power transmitted to it being proportional to E_1 F_1 will be diminished, and the load remaining the same, an augmentation of the displacement occurs; and the driver tends to race because A F_1 is diminished; therefore again the displacement will be increased.

If the displacement of C_1 and E_1 takes place towards M and S, A F_1 and E_1 F_1 are both increased.

Hence the follower will tend to race, and the driver to slacken in speed, both tending to increase the displacement.

As with a magnetic needle in a field of force there are two positions of equilibrium, one stable, the other unstable; but these points are not (as in the case of the magnetic needle) exactly opposite to one another. On the contrary, the two positions tend to approach each other as the electromotive forces tend to equality, and the angle between their positions is the angle through which the follower may be retarded without permanently upsetting the stability of the motion; but if the displacement exceed this amount, the follower would tend to fall back more and more, and would ultimately come to rest.

There are two positions for E in which no power is transmitted, viz., those which correspond to the points where the two circles S N E Q, B D Q A cut one another, Q and R. If E lies in the section Q S R, power is transmitted to the source C; but if E lie on the other portion of the circle it describes, power is exerted by the source C.

For any direction, A E, there exist generally two points where a line drawn from A cuts the circle S N E Q. Let E and E_2 be such a pair of points.

Let C_2 be the position of C corresponding to E_2.

Now, the power exerted by source A for this position will be $\frac{A E_2 . A F}{2R}$, and that exerted by source C will be

Digitized by Google

$\frac{AE_2 . FE_2}{2R}$. The relation of the latter to the former is $\frac{FE_2}{AF}$.

Now, as E_2 moves round from Q to R, on the line QE_2R, the above relation starts from zero, passes by positive values through a maximum value, and ends again at zero. There will therefore be two positions when the relation of the powers has a fixed value, and one of these will be a position of stability, the other unstable. These positions will alternate in the usual way with the cases of equilibrium for *transmission* of power. I apprehend that what Dr. Hopkinson has stated as regards the impossibility of placing working sources in series applies merely to sources of equal electromotive forces. In such a case MQ and N of Fig. 16 coincide with A, and two of the four positions giving $\frac{FE}{FA}$ a fixed value give a value zero to EA. Of the remaining two positions, one corresponding to transmission is stable; the other, where work is done by C, is unstable, and rigid connecting gearing would be required to maintain the motion.

(To be continued.)

IMITATION OF THE PHENOMENA OF ELECTRICITY AND MAGNETISM BY MEANS OF LIQUID OR GASEOUS CURRENTS.*

BY M. C. DECHARME.

(Concluded from page 96.)

It is not difficult to observe the steadiness of the liquid waves. The current of water issuing from a stationary tube vibrates longitudinally in the pipe and in the nozzle; at the moment when it meets the glass plate it spreads in concentric waves due to the resistance which opposes the liquid by friction. The steadiness is explained by the regular and even flow of the liquid.

For the imitation of *electro-chemical multiple rings* by means of continuous currents of water, I employ for each group a flat cylinder (Fig. 4), the lower surface of which is traversed by

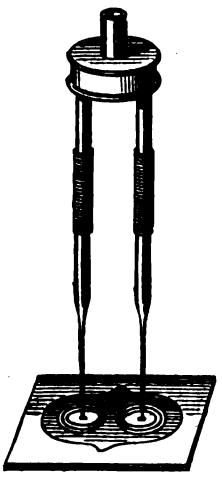

Fig. 4.

two, three, four, &c., parallel tubes, while the upper surface carries a single tube by which the water is admitted. When continuous currents are directed upon the plate of glass by these tubes, which are sufficiently close to permit of their *hydro-dynamic fields* encroaching upon each other, the waves are immediately influenced; they repel each other, are compressed, and confined within narrower limits than before. Figs. 5, 6, and 7 are examples of some of the diverse conformations which occur. It has been remarked that the weaker the liquids and the more moderate the height of the jets the more the forms of the simple or multiple rings approach to those of their electro-chemical prototypes. Near to the ends of the plate of projection, or close to a solid obstacle, the liquid waves, as with electric waves, have a tendency to dispersion or to assimilate themselves to the outlines of the obstacles which are

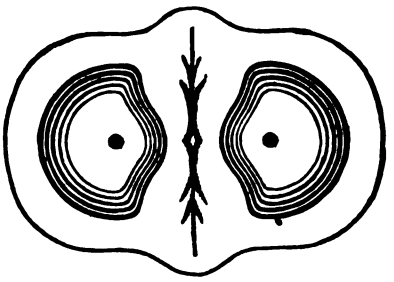

Fig. 5.

opposed to their free development. In the imitation of *bipolar* electro-chemical rings the method of aspiration of the liquid by means of a long syphon (such as, for instance, one of 7^m) may be resorted to, instead of that of the blowing or of the direct

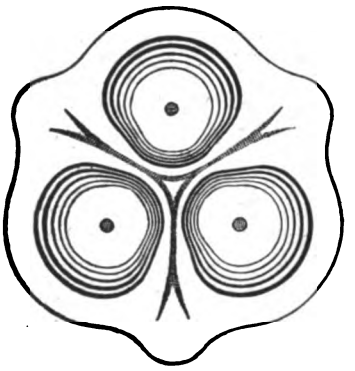

Fig. 6.

flow. Many peculiarities of the electro-chemical rings, such as the want of verticality of the electrodes, the inequality of distance from the points of the plate, the influence of various forms of these, the employ of lineal electrodes, &c., have their

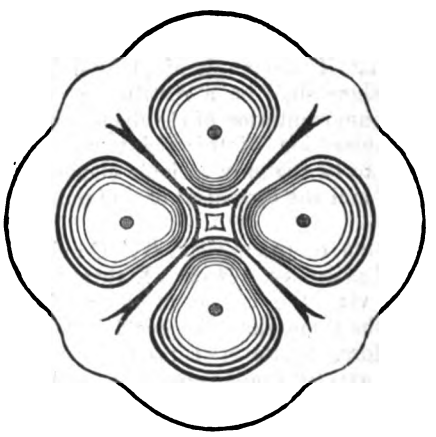

Fig. 7.

analogous effects in the hydro-dynamic rings we have been discussing.

IV. Physiological Effects.—Conclusions.

The instrument which I use to produce these effects I have named the *hydrodiapason*. It consists of a brass tube (of $0^m{\cdot}5$ in length, of $0^m{\cdot}006$ interior diameter, and $0^m{\cdot}001$ thick), bent in U form (Fig. 8.) The centre of one of the curved parts has an opening by which the tube is placed in communication with a nozzle of $0^m{\cdot}014$ interior diameter, screwed to a water pipe alimented by the waters of the town. The other curved part is cut so as to present two openings opposite to each other, and almost in contact. The apparatus may be fixed in any position, or may be held in the hand. As soon

* From the *Journal de Physique.*

Digitized by Google

as the current of water is passed through it it acquires a spontaneous and regular movement of vibration.

If the entire apparatus, or only its free ends, be placed in the water, the diapason acts very well, and the experiment is more easily performed. If the hydrodiapason be touched while it is in vibration (the instrument gives out the sound $la = 217$ vibrations per second) a very sensible *shock* will be received. It is a sensation very closely akin to that which is experienced

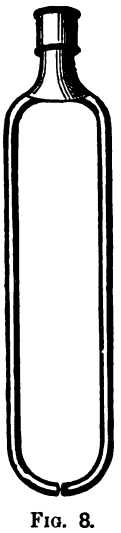

FIG. 8.

when the hands are placed upon the poles of a voltaic apparatus or of an induction coil of small power.

Summary of the Experiments. Comparison of Electric and Liquid Currents.—The phenomena of attraction, repulsion, and vibration which I have obtained with liquids in imitating the effects of electro-magnetism and of induction can also be produced with gaseous currents under more or less pressure. The greater number of the phenomena of static electricity can be imitated equally well with gaseous as with liquid currents; and, finally, the electro-chemical rings may either be produced by currents of air or by liquids, as in the preceding examples. It is not difficult to compare an electric current with a current of water flowing from a reservoir placed at a given height. Many fundamental laws are equally applicable to the two orders of phenomena. Ohm's formula $C = \frac{E}{R}$, which expresses the law of the electric flow, expresses also that of the flow of a liquid. The rapidity of the transmission of pressure in liquids is more especially comparable with the action which takes place with electric currents; the hydraulic telegraph of M. Tommasi has given ample proof of this. In a word, the laws of the propagation of electricity in the *variable period* and in the *permanent state* are analagous to those of the flow of liquids. The laws of derived currents are also common to the two orders of phenomena. In fact the electric current may, in very many cases, be regarded as the movement of an incompressible fluid obeying mechanical laws. The higher the E.M.F. of the current the more the effects which it produces approach in similarity to those of a liquid current.

When an electric current passes from a metallic conductor of large section to a fine wire, it heats the latter, turns it red, and finally volatilises it.

When a liquid current of high pressure passes from a large tube to another which is flexible and narrow (such as an india rubber tube of $5^{mm.}$ in diameter and $1^{mm.}$ thick), it tends to distend, twist, and finally to burst it. The analogy between these two effects are self-evident.

Conclusions.—After having initiated by means of gaseous or liquid currents, in a great variety of experiments, the principal phenomena of electro-magnetism, induction, electro-chemistry, and electro-physiology, I feel that I have some reason for my conclusions upon the analogy of the effects and the analogy of the causes, and for believing that electric and magnetic phenomena are closely allied to hydro-dynamic phenomena—that is to say, that electricity in the form of a *current* (of ether or of ponderable matter) is analogous to a liquid current.

LEGAL.

The Queen v. the Postmaster-General.

This was an application on the part of the Great Western Railway Company for a mandamus to the Postmaster-General to take proceedings to compensate them for the use by him of one of their subordinate lines (the Llynvi and Ogmore) for the purposes of the telegraph. In 1864 the Electric Telegraph Company agreed for fourteen years to construct and maintain telegraphs and keep up telegraphic communication on the Llynvi and Ogmore Railway, to be used for public purposes by the telegraph company and for railway messages by the railway company. The question turned upon the effect of an agreement, providing that the Postmaster-General might acquire the telegraph undertakings of railway companies, on certain terms of compensation, and that "the railway company might at any time require the Postmaster-General to extend the provisions of the agreement so as to include any present or future lines leased or worked by them, if they should make arrangements to that effect with the owners of those lines, but subject to any agreements theretofore made between the owners of such lines and the Postmaster-General." Then it was provided that the Postmaster-General should pay the "railway company certain sums by way of compensation, as twenty years' purchase of the amount of the net annual profits of telegraphs over the wires of the railway company," and in 1882 the Great Western Railway Company also claimed payment, by way of compensation, of sums amounting to about £22,000, and also a yearly rent of £1. 3s. per mile per wire, with arrears. The Postmaster-General refused to entertain the claim, on the ground that that there was no such agreement in existence as could be a subject of compensation under the agreement of 1868, and hence this application.

Mr. Justice MATHEW read a written judgment in favour of the Postmaster-General. The question, he said, for our determination is whether the agreement of 1868 can be treated as having extended to the Llynvi and Ogmore lines. The main purpose of that agreement seems to have been to provide for the performance of the duties which would devolve on the Postmaster-General upon the transfer to him of the undertakings of the Electric Telegraph Company under the contracts entered into. The lines specified were all lines which were the subject of existing telegraph contracts. The agreement did not apply, and was not intended to apply, to any line to be afterwards constructed by the Great Western Railway Company, and the reason seems plain. Such a line would not be one in respect of which the Postmaster-General would come under any obligation by reason of the transfer to him of telegraph undertakings, and would, therefore, not be within the scope of the agreement. Under the agreement it was to be extended to "present or future lines leased or worked by the railway company, if they made arrangements to that effect with the owners of those line." What were those "arrangements?" We do not doubt they were those which would be indispensable in order that the agreement should apply, viz.:—(1) That the owners of the lines should accept the Great Western Railway Company as contractors with them for the telegraph service of their lines; and (2) that they should adopt the terms of the agreement of 1868 in lieu of the terms of any former contracts with telegraph companies. If this view of the meaning of the contract be correct, it seems clear that the Great Western Railway Company are wrong in their contention that the agreement can be made to extend to the Llynvi and Ogmore lines. Down to the expiration of the respective periods of 14 years (if the contracts had not ended at an earlier period) the Postmaster-General would seem to have been liable for the performance of these contracts to the Llynvi and Ogmore Company. When the contract ended or expired, the Postmaster-General was free to make a fresh contract either with the Llynvi and Ogmore Company or with the Great Western Company, and some temporary arrangement was, in point of fact, made for working the telegraphs on the Llynvi and Ogmore lines by the Great Western Company. In the absence of any definite agreement, the Llynvi and Ogmore Company, or, it may be, the Great Western Railway Company, would be entitled in accordance with the contracts to use these telegraphs for railway messages—to require the Postmaster-General to remove from the lines any telegraph apparatus used exclusively for public purposes. No steps were taken to compel their removal, nor was any demand made against the Postmaster-General for compensation until 1882, when the contracts had for some time expired. It does not appear that the arrangements between the two railway companies were such as were contemplated by the agreement of 1868. There was not in 1882 any such subsisting agreement for telegraph purposes in respect of the Llynvi and Ogmore lines as would give rise to any legal claims against the Postmaster-General. On this ground we think that there could have been no extension of the agrement of 1868 to the Llynvi and Ogmore lines. We also think that if the supposed arrangement had been made with the Llynvi and Ogmore Company before the expiration of the agreements, the extension of the contract could not have been made so as to give the Great Western Railway Company any right to the compensation now claimed. The contracts could not have been made the subject of a claim for compensation under the Act of 1868, and the agreement, it appears to us, was not intended to have any wider scope than the statute. The agreement of 1868 appears to us to have been incapable of being applied except (1) where there was subsisting contracts with telegraph companies, and (2) where those contracts conferred upon the railway company the right to be compensated as provided by that agreement. The agreements between the Llynvi and Ogmore Company and the Telegraph Company were not of this character, as they conferred no right on the company to carry on the business of transmitting messages for money.—Rule therefore discharged with costs.

ELECTRICITY AND LIGHTHOUSES.

That the application of electricity to the purposes of lighthouse illumination and for connecting lightships with the mainland occupied so prominent a place in the speeches at the Trinity House banquet is a fact highly complimentary to electrical science, and very encouraging to electrical engineers. The two great practical questions of providing lighthouses with the most powerful of all illuminants, and of establishing telegraphic communication with lightships, may still be said to be in their experimental stage; but there is reasonable ground for anticipating that in due time they will be answered satisfactorily. The Trinity House has not yet completed its report on the exhaustive investigations which have been recently made to test the relative value of different illuminants for lighthouses—that is to say, of gas, oil, and electric light; but we may confidently predict that for certain positions, and under given conditions, the latter will be pronounced superior to either of its rivals. For climatic reasons it would seem that this method of illuminating lighthouses has made greater progress on foreign stations than on our own fog-bound shores; but even here the London Trinity Board alone have five such seafarers' beacons lighted by electricity; and the most recent of them, the St. Catherine's Lighthouse, in the Isle of Wight, now nearly completed, will possess the most powerful electric light in the world. It is needless, in the face of these facts, to enter into the vexed question of the penetrating quality of the electric light. The ancient corporation at whose hospitable board the Duke of Edinburgh presided the other evening is undoubtedly the most influential body of the kind in existence; their authority is appealed to, if not enforced, as his Royal Highness observed, throughout the whole maritime world; and it is not probable that they would take the responsibility of adopting the electric light for highly important positions if it did not possess substantial and unquestionable superiority. There are obvious reasons for not altering the character of old established lights; but as the conscience of every seafaring nation is quickened by the increase of sea-going traffic, the necessity for multiplying these safeguards against disaster is more and more recognised, and the claims of the electric light for all new erections are not likely to be overlooked.

A similar humane motive has latterly prompted the desire to establish communication between the shore and the lightships, great numbers of which are located within short distances of land, but which have no sure means in bad weather of instantaneously signalling for help when it is most needed. Lightships are moored exactly at those spots where the danger is greatest, and where in point of fact the greatest number of accidents do occur to vessels that are within sight of land. The lightship service itself is one of no small danger, the vessel being frequently fouled and sometimes sunk either by stress of weather or by what the Duke of Edinburgh in nautical phraseology called close shaving. Obviously it is desirable to resort to the telegraph to inform the nearest lifeboat station as to any disaster observed from the deck of the light vessel not visible to the lookout men on shore, its precise nature and its exact locality. Signal rockets supply such information but very inadequately, and in unfavourable weather not at all. Full and rapid information, independently of time and season, would often be the means of rescuing many precious lives, to say nothing of the saving of much valuable property. The expense of establishing such a system and of maintaining it, we may be sure, would be quite a secondary consideration if the thing were practicable. But it must be confessed that there are great difficulties to be encountered and many curious problems to be solved which the general public are little aware of. We pointed out last December that the light ships, though moored generally in comparatively shallow water, are obliged to have their cables payed out to allow for rise of tide and rough weather, so that the vessels swing easy at all times. In this way they often describe a circle of considerable dimensions; and on this account if no other it would be impossible to attach a submarine cable in the usual way, or indeed to have it separately attached at all.

One or more ingenious contrivances were invented to admit of the telegraph cable twisting and turning as much as it pleased, theoretically, without getting kinked or losing electrical continuity; bnt it soon became evident that even if the telegraph cable thus accommodated could take care of itself if left to itself, it would instantly come to grief if the ship's cable fell foul of it, which was sure to happen the first time the ship swung round. Hence it was decided that the two cables must somehow be combined; and, after a lengthened preliminary series of experiments at their works, the Telegraph Construction and Maintenance Company devised a cable which was to serve the double purpose of mooring the lightship and connecting it electrically with a submarine telegraph cable proceeding from the anchorage in the usual way to shore. A hollow steel wire rope, 8½in. in circumference, formed by fourteen twisted strands, was ultimately adopted. This rope, which took the place of the chain cable attached to the anchor, was capable of bearing a strain of 70 tons, and had the insulated telegraph wire running through its centre. The efficiency of this device was tried, as our readers are aware, six months ago, on what is called the "Sunk" lightship, situated about nine miles off Walton-on-the-Naze, from which place instant communication with Harwich and the neighbouring lifeboat

Digitized by Google

stations can be kept up. The experiment, which may be called a speculative one, inasmuch as no payment was to be made in case of failure, proved highly encouraging. Since the beginning of March the Sunk lightship has been in telegraphic communication with the shore, and we hear of no difficulties in maintaining it that are likely to be insurmountable. As the Duke of Edinburgh observed, we cannot yet be positive that all the difficulties attending such undertakings will everywhere be overcome; but a good beginning has been made, and the country, as well as the enterprising firm who are entitled to the credit of it, may be heartily congratulated on the prospects of this most beneficent work.

CORRESPONDENCE.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The fact that the Miller Prize has been awarded by the Council of the Institution of Civil Engineers to Mr. F. G. Howard, for his paper on "Secondary Batteries," attaches to that communication a certain importance. Students will regard it as the latest information on the subject; but it appears that the author is not well acquainted with the latest forms of secondary batteries, nor with their recent applications. I do not wish to depreciate the value of the paper, which in many points is exceedingly interesting and instructive, but I wonder why Mr. Howard finished off with a period (the Vienna Exhibition of 1883) when secondary batteries, and especially their applications, were so little understood.

It behoves those who have gained experience with these appliances since Mr. Howard relinquished the task of making notes on the progress of certain types of cells to supplement the information supplied at the students' meeting of the institution a few months ago; there are, moreover, several statements which require modification or explanation. Taking them in consecutive order, we find first a table giving the "Storage capacity of various secondary batteries as regards ratio of work to weight," and then stands a "theoretically perfect" cell with a storage capacity of 360,000 foot-pounds with the highest percentage of efficiency = 100.

We know that the energy evolved by the oxidation of a pound of lead is equivalent to 360,000 foot-pounds, but we cannot conceive an ideal *battery* where, even if every atom be active, that amount of work could be put in. The comparison of efficiency thus established is not a happy one, and it is misleading; the batteries referred to in that table are all made of lead, and if the comparison or the "efficiency" refers to a peculiar arrangement of the materials the "theoretically perfect" cell should be left out, and instead of "efficiency" call it relative capacity, or establish a coefficient if such were deemed useful.

Mr. Howard states, and others have said, that "the advantages of accumulators made after the Planté type over those of the Faure type are that they afford a far higher rate of discharge. This property is invaluable for many purposes, as, for instance, where numerous lamps are required to be run for only a short time." By Faure type, I presume is meant a battery with lead oxides. It would be exceedingly interesting to know whether the two types referred to have ever been discharged side by side, say supplying 100 lamps for half an hour, two batteries of equal weight discharging at the same rate.

As regards the durability of the Sellon-Volckmar type and the effect of overcharging the author seems ill-informed; at any rate the batteries made by the Storage Company within the last twelve months have given great satisfaction, of which fact anyone could satisfy himself with very little trouble. With properly constructed batteries this overcharging is not such a serious matter as is generally supposed.

Why should the Planté accumulator arrive at its "maximum efficiency" when "it is on the point of falling to pieces?" The Planté plate has its highest *storage capacity* when it gets thoroughly disintegrated; but surely the *efficiency* has nothing to do with the period of existence.

Mr. Howard advises his audience to test the cells from time to time "by taking a short length of stout wire, holding one end upon one pole of the cell to be tested, and striking the opposite pole with the other end of the wire." This is an old-fashioned, clumsy, and, to novices, dangerous method. The proper way is to use a low constant voltmeter or a detector, and observe the deflection of the needle upon a scale, taking one cell at a time. Thereby we can see not only whether the cell is *quite* discharged, but also whether the E.M.F. is low, and, further, whether a reversal has taken place in any one cell, in which case the needle will deflect the wrong way relatively to the terminals of the plates.

With regard to the employment of secondary batteries for tram cars and boats, I may state that there has been more real practical work done *since* 1883, where Mr. Howard leaves off, than at any previous time.

The "Electricity," which was launched in 1882, has been altered in the spring, 1883, by taking the counteshaft out, and running the screw direct from the armature of the motor. This was considered impracticable by marine engineers, and Messrs. Yarrow and Co. could only be convinced of the efficiency of the working of a high speed propeller after I had completed a series of experiments, when they adopted the same plan in the Vienna launch. This I mention because Messrs. Yarrow and Co. receive generally the credit for this innovation.

The electric launch, "Australia," has been in successful operation since last summer, and her cells, which have had a fair amount of work to do, have not cost their owners one penny for repairs; they are still in perfect order, as well as the motor. Whereas the motor in the launch, "Electricity," weighed 658lbs., and took 46 amperes with 90 volts, the motor of the "Australia" (a slightly larger boat) weighs 390lbs., and absorbed 36 amperes with 100 volts at the same rate of speed of boat.

Electric launches of different sizes are now in course of construction.

Great activity has been shown in the development of electric tram cars during the last year. The car which has been described in your journal in December last has had severe tests since the beginning of October, partly on that stiff line at Millwall, and partly at Battersea. The difference between this car and the one mentioned by Mr. Howard is very great. The new accumulators weigh and measure just one half of the former; the motor also absorbs one half the current for the same speed of car.

The tram car cells contain 26lb. (each) of lead plates; they are charged at the rate of 32 amperes, and discharged at an average rate of 46 amperes; mounting stiff inclines they give 100 to 150 amperes, on the level 30 to 35 amperes with loaded car. These cells have been working for eight months and they are still in splendid condition—it would do Mr. Howard good to see them. When the car is not running these cells are kept at work for other purposes, in order to ascertain their durability. Another tram car of exactly similar design to this last one has just been shipped to Cologne, and there are signs which encourage the idea that electric propulsion by means of secondary batteries will receive a practical development on the continents of Europe and America before certain prejudices and red tapeism in this country will be overcome.

If Mr. Howard chooses to read another paper on the same subject he will find ample new material, and I am sure he will receive plenty of information for the mere asking for it, and he will be invited to make his own observations if it is for the purpose of instructing those who still look upon secondary batteries as laboratory toys.—Yours, &c.,

A. RECKENZAUN.

60, Queen Victoria-street, E.C., 20th June, 1885.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I fear that many outsiders reading Mr. G. Howard's paper upon secondary batteries will jump too readily at the

Digitized by Google

conclusion that they are "hopeless," an impression which I am sure the author had no intention of conveying, being himself, I venture to think, a full believer in them. He has not, it is true, called in question their convenience, their economy, and, under very many conditions, their indispensability; but the conclusion which might be deduced from his statement as to their durability over-rides all these considerations, and if not modified might, to some extent, stand in the way of their general employment.

In Mr. Howard's experience one of two things must have occurred—either the batteries upon which he bases his statement were very badly made, or they were very badly used. In either case the period of their life may have been as readily but a few weeks, or even days, as the few months he accords to them. Unfortunately there is no doubt that many of the batteries constructed at a certain period by the chief manufacturing company, as also by other persons, were seriously defective in one or more points. Imperfect formation, bad connections, unsound containers, disproportion to the work for which they were to be applied, were faults consequent upon carelessness and inexperience, and all these elements have played their part in bringing about untoward results. But such mishaps, however occasioned, have no real bearing upon their practical usefulness or otherwise, and it would be not only unjust to those interested, but unfortunate as regards scientific and industrial progress, if preventable causes are taken into account in considering the abstract principles of utility and success.

I should have been delighted had Mr. Howard favoured me with a few inquiries before dealing so summarily with a subject of vast scientific and commercial importance, and I could, I venture to think, have resolved many doubts he appears to entertain, and convinced him that sufficient time has not as yet elapsed since the employment of the forms of secondary batteries to which he alludes to arrive at any accurate data for estimating their length of life.

So far as the forms in which I am interested are concerned, no failure has come under my notice which has not on investigation been satisfactorily accounted for. I say satisfactorily, in the sense of having been proved to have arisen from remediable causes entirely unconnected with the principle involved. I can show Mr. Howard cells which, with the exception of occasional intervals of a few weeks, have been in full and regular work since they were first manufactured under my specification before any commercial development took place, viz., the spring of 1882, a period of three full years, and their present still perfect condition warrants the assumption that they will do duty for as many years more. *Care in manufacture and ordinary attention to rules for working are all that is essential to make this a normal condition*, and the evils of buckling, of undue sulphating, of short-circuiting, and of local action (the latter causing the separation of the active material from the conducting frame or support) need never occur, and should now be things of the past.

I will not at present further encroach upon your space to touch upon some points in Mr. Howard's paper which are open to remark, such as his suggested mode of testing, &c., but I would wish to remove the impression he conveys that "skilled" supervision is necessary. Intending installers of the electric light might be unduly influenced against its adoption if they supposed that they must keep an electrician on the premises. My experience over some years is that once installed on right principles and under competent supervision, there is nothing in the working of the electric light either in respect of the engine, the dynamo, or the accumulators which is beyond the capacity of an under gardener or labourer of average intelligence, after a few days' training.

The work and anxiety to those engaged (whether as amateurs or commercially) in pressing forward the introduction of electric light has indeed been an up-hill one, and now that the initiatory labour is, it may be hoped, drawing to a successful issue, and the practical and beneficial results within measurable distance, it would be disheartening if any purely imaginary difficulties are raised as bugbears, which cannot fail to retard its development.

With regard to the immense employment which is in prospect for electrical accumulators, my views have been pretty generally known, and as time passes they are, I am happy to say, being slowly but surely justified and confirmed. Already most of my friends, some of them distinguished electricians—who in the early days good-naturedly laughed at my enthusiasm and confidence in their ultimate success—freely recognise and admit their necessity, and the important part which they are destined to play in the great commercial industries now rapidly growing out of the utilisation of electricity.—Yours, &c.,

JOHN S. SELLON.

The Hall, Sydenham, 24th June, 1885.

NOMINAL CANDLE-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Philadelphia report on arc lamps appears at first sight to give information on an important point on which hardly any published statements have been made, viz., the relation between electric energy and the light of arc lamps.

In the early days enthusiastic companies measured the light concentrated in one direction, with carbons out of line, as is done with a search light, and called this the nominal candle-power. The figures 1,200 and 2,000 opposite the name Brush appear to be relics of these times.

We were recently asked to estimate for some 25 arc light dynamos to give lights of 3,000 candle-power, with an 8-ampere current, and on expressing a preference to designate the out-put by the amperes rather than by the candle-power were told that nominal candle-power was meant; it therefore appears quite time that some definite knowledge should exist on this point.

The report is, however, very disappointing, and it does not add much to our scanty knowledge. Examining it by the aid of the graphical method, plotting current as ordinates, and candle-power as abscissæ, and taking the 45 deg. ray in each case, the points are scattered like stars. The two Brush lamps, and the two Van de Poeles seem to lie on lines of their own, passing through a point somewhere in the neighbourhood of the origin of co-ordinates; but the others are anywhere, though the diversity of the volts would not lead one to expect much regularity.

Plotting watts against candle-power gives hardly any better result; neglecting Arago and the Western Company, the rest seem at first sight to lie somewhere round the line of 1,000 candle-power to the kilowatt, or 0·5 watt to the candle.

In a recent conversation with one of the first electric engineers of the day, he gave his opinion that 10 amperes should give about 1,000 candle-power, and 20 amperes 3,000 candle power. Taking 12 amperes at the mean volts (neglecting the Western Company), say 42, which means a rather longer arc than is usual, 1,000 candle-power should be given at 45 deg. On closer inspection of the various measurements, omitting the 1,200 candle-power Brush and the two already mentioned, a curve of $\text{candle-power} = \frac{\text{watts}^2}{300}$ appears to satisfy them fairly. With 950 watts, say 43 volts and 22 amperes, this formula gives 3,000 candle-power, which is singularly near the estimate given above.

A trial of different kinds of carbons is a much easier matter than photometric measurement, and they seem to affect the colour and steadiness of the light much more than its intensity. As long as a carbon gives a good white light and does not form mushrooms or ash, and does not burn away at an extravagant rate, there does not appear much to choose among the well known brands.

It is very satisfactory to find that the distribution of the light in different lamps is so nearly the same, but the information given by the measurements would be far more valuable had the diameter of the carbons and the length of the arcs been given. There are not enough data to show whether the long arcs give a less concentrated distribution or not. It would be interesting to hear more about Richter and Diehl. The former appears not to have been tested at its best angle; they both give an unusual distribution with a fair efficiency.

This subject of the power of arc lamps is one in which the

Digitized by Google

public is at our mercy. Very few people who have bought an electric light plant for arc lights would take the trouble to measure their candle-power, and they would not be much the wiser if they did. But there ought to be some fair guide as to what is a 300 candle-power arc and what is a 3,000 candle-power. The matter cannot well be taken up by any scientific society as at present constituted, and we have no Franklin Institute, though there is more than one educational establishment that should be able to carry out the requisite tests and lay them before the scientific world.

In the meantime, sir, a practical discussion in your columns would help to enlighten both electrical engineers and their clients.—Yours, &c., ALEX. P. TROTTER.

Halifax, 20th June, 1885.

ON AN UNEXPECTED SOURCE OF ERROR IN TAKING GALVANOMETRIC READINGS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When engaged lately in testing the E.M.F. of several cells by means of a coil of very high resistance and one of Sir William Thomson's magnetometers, I was puzzled to find that the results did not properly agree with each other. My general practice was to get into position so that the index covered its reflection in the mirror below just when pressing down the key which allowed the current to pass through the coil. But on one occasion I happened to draw back from the magnetometer and again approach it when the needle was at rest, and was surprised to see it move. I searched my pockets to make sure that I had nothing magnetic there; but everything had been laid aside. I then caused various parts of my clothing to approach the needle in case there might be something concealed in the lining; but I got no response till I put my head near it. As I did not think my head was likely to be magnetic, although in my first surprise I actually tried it, I took off my hat, and found that it pulled the needle a good many degrees from zero. I found also that my hat had well-defined poles—the front repelling the N seeking end of magnets, and the back attracting them. It was an ordinary round felt had. On closely examining it, I found that a small steel wire was sewn into the brim to stiffen it. I imagine that many electricians are not aware of this. An interesting question was raised by the result of trying a number of hats. One had no wire and no action. All the rest acted, but the surprising thing was that all the hats, although worn by different people, and bought in different shops, were similarly polarised. All the fronts were N seeking poles. The first thing that naturally occurred to one was to wonder if it could be possible that the magnetisation was produced by the heads which wore them; but I came to the conclusion that the explanation was much more commonplace. Nearly everybody on taking off his hat hangs it up with the front side down. When you grip the hat by the front, and the peg is above you, it is the easiest way. And so the earth's influence develops the observed polarity. But I cannot dogmatise on this interesting subject, as my experiments were few and rough, and made on the "spur of the moment." My object in writing is to warn others to take off their hats when using magnetometers.—Yours, &c., JNO. M. M. MUNRO.

BLIND MATHEMATICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see that I must lead your correspondent back to Ohm's law. E in this law indicates *solely* the difference of potential between the ends of a resistance, R, carrying a current, C, and not any E.M.F. in the same circuit acting outside this resistance. Hence it has the same meaning in the heat formula in question.

Single out from any working circuit a part of it having resistance R. A definite difference of potential, E, will exist between its ends, and the current through it be $\frac{E}{R}$. The heat or work developed per second in it is either $C^2 R$, $\frac{E^2}{R}$, or C E; the last two obtained by substituting values of C and R from Ohm's law.

Which shall we use? *Any one*, but for simplicity we select that which includes the data available. Do we therefore "abandon" the other two and treat them as false? Nothing more absurd. Take instances.

You require to know the energy absorbed, (1) in the main and return leads between a dynamo and a system of lamps. You have an ammeter in the circuit, and you know the resistance of the leads. Which is the readiest expression to use? $C^2 R$.

(2). In some portion of a circuit in which no ammeter is placed, or where it may be inconvenient to place one, such as the shunt coil either of an arc lamp or a shunt machine. Nothing is simpler than to use your voltmeter and $\frac{E^2}{R}$.

(3). In an arc lamp do we know the resistance of the arc *per se*? No; it depends on the regulation. What is easier than to read off the current in the main circuit, taking a simultaneous reading at the lamp terminals with the voltmeter and employing C E?

Many other instances occur in practice.

$\frac{E^2}{R}$ is applicable, of course, to the two wires in series, E being, as defined above, the differences of potential at their respective ends, which for the platinum is six times the silver, whatever current. But it is simpler to use $C^2 R$ here. Should $\frac{E^2}{R}$ be therefore shelved as useless? Certainly not, as the above instances show. We see also that resistance favours heating under some conditions, while it hinders it under others. These conditions must not be ignored.

I trust this will suffice to convince Mr. Williams of the exactness and utility of these expressions, thus sparing any further space being occupied under the above heading.—Yours, &c., H. D. WILKINSON.

School of Electrical Engineering,
Hanover-square, W.

THE NEW CABLE SHIP "BRITANNIA."

On Tuesday last, at the invitation of the Telegraph Construction and Maintenance Company, a number of gentlemen interested in submarine telegraphy visited Greenwich to inspect the new ss. "Britannia," recently built for the company by Messrs. Laird, of Birkenhead, and now lying off the Company's wharf at Greenwich. Among the guests may be noticed the following gentlemen:—

The Directors of the Telegraph Construction and Maintenance Company:—Sir Daniell Gooch, Bart., M.P.; Lord Alfred Paget, Sir George Elliott, Bart., M.P.; Vice-Admiral Sir George H. Richards, F.R.S.; Mr. G. W. Campbell, and Mr. Philip Rawson.

The Maharajah of Johore and suite, Prince Khalid, Inchi Abdul Rahman, and Inchi Abdullah.

Lord Hawke, Admiral Sir H. Keppel, G.C.B.; Mr. Pender, M.P.; Sir James Anderson, Sir William M'Arthur, M.P.; Hon. W. St. John Brodrick, M.P.; Count Oscar Von Reichenbach, Mr. Patey, Mr. W. Ford, Mr. W. Barber, Mr. John Collett (Director of Contracts, Admiralty); Mr. W. S. Baughan, C.B. (Director of Transports); Mr. C. W. Stronge, C.B.; Mr. Cyrus W. Field, Mr. D. H. Goodsall, Mr. Graves, Mr. Preece, Mr. Youle, Mr. Shuter, Captain Halpin, Mr. Willoughby Smith, Mr. Clifford, Mr. Nielsen, Mr. Latimer Clark, M.I.C.E.; Mr. H. C. Forde, M.I.C.E.; Mr. Herbert Taylor, Mr. Floersheim, Mr. Schott, Mr. John Laird, Mr. H. W. Jewesbury, Mr. D. Jewesbury, Mr. Draper, Mr. R. Cunningham, Mr. Cracknell, Superintendent of Telegraphs, N. S. Wales; Mr. Todd, Postmaster-General, South Australia; Mr. W. C. Johnson, Mr. S. Phillips, Mr. F. E. Hesse, Dr. Allchin, Mr. John Temple, Mr. Kenneth Anderson, Mr. H. Weaver, Mr. G. G. Nicol, Mr. T. Fuller, Mr. Henry Dover, Mr. Payton, Mr. Lucas, Mr. Dickens, Captain Manning, Captain Cato, Mr. Saunders, Mr. R. Collett, Mr. J. W. Fuller, &c.

Digitized by Google

Many of the guests met together at the Old Swan Pier, London Bridge, and proceeded to Greenwich in a special steamboat, which drew alongside of the new ss. "Britannia." This vessel presented a very pretty view from the water. She is built of steel of full iron scantling, by Messrs. Laird, of Birkenhead, has a length of 240ft., with a beam of 34ft., and a measurement of about 1,500 tons. She has twin screws, driven by two pairs of compound surface condensing engines of 1,300 horse-power, also built by Messrs. Laird. On her trial trip, with the engines developing 1,370 horse-power, she made an average of 12½ knots. She has a flush deck, and has three cable tanks, two forward and one aft the engines. The decks are of steel, covered with teak. The vessel carries Kirkaldy's condensing apparatus, similar to that on board the "Calabria" and "Kangaroo," so that if necessary 6,000 gallons of fresh water can be condensed per day. There are three water-tight bulkheads, according to the requirements of the Board of Trade. She also carries water ballast tanks, with a capacity of about 350 tons. The masts and yards are of steel. The arrangements for the comfort of the crew are very good, but the fittings throughout the ship are plain, and are so arranged that with the utmost facility they can be removed, and the skin of the ship got to. The saloon is fitted with polished Dantzic oak, with teak panels, &c. In place of the usual swinging trays, it is fitted with a handsome sideboard with cupboards to answer instead of such trays, and with fixed revolving chairs. The cabins are fitted with iron-framed berths having steel spring bottoms, and, in fact, throughout, every effort has been made to obtain a maximum of comfort without ornateness or expense. The boats are six in number, diagonally built and specially fitted for cable work with Clarkson's patent flotation and Liardet's patent disengaging gear. The vessel has been designed throughout by Captain Halpin, somewhat on the lines of the "Scotia," with all the improvements that experience has suggested, and there is no doubt that he must be credited with having obtained one of the best adapted vessels afloat for the particular work for which it is designed. The "Britannia" is now anchored off the Telegraph Construction and Maintenance Company's Works, in order to be fitted with cable gear and the apparatus necessary for cable work. She will carry picking up and laying down gear, the whole of which will be manufactured by the Telegraph Construction and Maintenance Company. The whole gear, in fact, will be of that company's own manufacture.

After the inspection of the "Britannia" the company went on board the "Seine," where an excellent lunch had been provided under the direction of the proprietor of the Ship Hotel at Greenwich. We may here remark that the "Seine" has been taking on board the duplicate cable manufactured by the company for the Zanzibar and Mozambique section of the South-East African Cable Company. The "Seine" is expected to sail shortly. This duplicate section will probably be laid about August next. Many of our readers will recollect that faults have developed in this section under peculiar circumstances, and an effort is now being made to remedy any future breakdown by duplicating the cable, the new cable being laid much further out at sea.

The principal toasts at the luncheon were "The Queen," "The Builders of the 'Britannia'"—responded to by Mr. Laird—"The Maharajah"—responded to by the Maharajah of Johore in the soft breathing words of the Malayan tongue—and "The Cable Companies"—responded to by Mr. John Pender, M.P.

ELECTRICAL GYMNASTICS.—An electric dumb-bell has been devised with the view of effecting a stimulation of the nerves simultaneously with the exercise of the muscles. It is said that when holding the electrodes in the hands quietly the most marked contraction is generally produced in the muscles of the forearm. When, however, the arm is moved about, as in dumb-bell exercises, the result is a constant change in the effect upon the muscles, all of which are more or less affected according to the position of the arm. This result is obtained by enclosing an induction coil and battery within the dumb-bell, so that it performs the functions of both muscular and nervous stimulator at the same time.

ON THE CALCULATION OF MAINS FOR THE DISTRIBUTION OF ELECTRICITY.*

BY W. H. SNELL, ASSOCIATE.

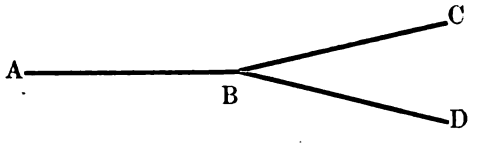
(Continued from page 104.)

ERRATA.—On page 104, second line from the bottom, the formula should read

$$N_1 = \sqrt{\frac{n^2 t_1}{T}} \text{ and } N_2 = \sqrt{\frac{m^2 t_2}{T}};$$

on the same page, line 21 from the top, N_1 should read M_1.

Let us now suppose a case in illustration of these formulæ. Let there be a feeder, A B, which splits into two branches B C



and B D. The data for the two branches being given, it is required to find the thermal current in the feeder—or the number of lamps to which it corresponds. We have given

(for B C)	(for B D)
$\mu_1 = 400$	$\mu_2 = 250$
$M_1 = 60$	$M_2 = 40$
$t_1 = 5$	$t_2 = 6$

We must suppose that N_1 and N_2 have also been independently calculated (by means of equation (4), or certain developments of that equation, which we shall presently consider); but in order that we may not assign for them impossible values, we will find the limits of N_1 and N_2 by means of equations (8) and (10).

N_1 lies between $\left\{ \sqrt{M_1 \mu_1} = 155 \right\}$ and $\left\{ M_1 \sqrt{\frac{T}{t}} = 131 \right\}$

N_2 " " $\left\{ \sqrt{M_1 \mu_1} = 100 \right\}$ and $\left\{ M_2 \sqrt{\frac{T}{t_1}} = 80 \right\}$

Suppose we put $N_1 = 140$ and $N_2 = 90$, assuming, as we have already said, that these particular values have been obtained by an independent method of calculation, then we know that

$$N \text{ lies between } (M_1 + M_2)\sqrt{\frac{T}{t}} \text{ and } (N_1 + N_2).$$

We may, if we like, obtain the exact value of t by means of (20), or, using (21), we can see that $t = 5{\cdot}25$ nearly, say $t = 5{\cdot}2$. We shall now obtain

$$(M_1 + M_2)\sqrt{\frac{T}{t}} = 215, \text{ and } (N_1 + N_2) = 230;$$

so that N lies between 215 and 230.

It will be interesting to find the numerical values of the other limits. We shall find that

$$\sqrt{N_1^2 + N_2^2} = 167, \text{ and } \sqrt{\{(\mu_1 + \mu_2)(M_1 + M_2)\}} = 255.$$

The reason why the three superior values happen to be comparatively near together is that the values of t_1 and t_2 were taken rather near τ_1 and τ_2.

It is evident that as regards the maximum limit of N the formula is applicable to the collation of any number of terms at once, and for the inferior limit all terms having nearly the same values of t can be taken together, and the remaining terms can be taken successively by means of equation (20).

Having arrived at this point we can see that if the lamps upon any given section are classed in any number of divisions, and if for each division we can calculate the values of M and N with any probable degree of accuracy, we shall afterwards be able to collate these divisions and find the limiting values of the thermal current for the whole section. But, further, our knowledge of the method according to which the lamps have been classed in the several divisions will in each case

*Paper read before the Society of Telegraph-Engineers and Electricians.

Digitized by Google

suggest a means of arriving, with more or less accuracy, at the value of A in equation (14). We shall thus get still nearer to the most probable value of N for the whole section.

After this we shall have to collate the thermal currents of the various sections with each other, working up towards the machines, but here we shall have to rely almost entirely upon the method of limits. It should, however, be noted that at any point in the process the ratio between the superior and inferior limits of the final thermal current for any given section will be *less* than the (arithmetical) mean value of the ratios between the limiting values of N_1, N_2, &c., from which it is obtained, except in the case when all these ratios are equal. For example, taking the first section—and, therefore, the largest conductor—although the *difference* between the superior and inferior limits of the possible values of N is here at a maximum, yet the *ratio* between these two values cannot in any case be greater than the mean values of the ratios of the values of N_1, N_2, ... for all the other sections.

We have yet another step which it may sometimes be worth while to take. At any point in the process of collating the values for the separate sections we can make a direct calculation of the value of the thermal current for all the lamps which are supplied through that section, by proceeding as though all lamps lying beyond were connected directly to that section, finding the thermal current for the different groups, and collating as before. But although this process may be valuable as a check, especially in the case of some of the larger mains, it will be seen in the sequel that in most cases it involves very long and somewhat complex calculations.

One other point may be mentioned here. We have been obliged always to assume that the current supplied to the lamps connected directly to any given section flowed through its whole length. Virtually we treat the case in which all the lamps are placed at the extreme end of the section to which they are connected. The error thus introduced is of course one of excess. It may be minimised by judiciously placing the sections, and also by increasing their number. It may sometimes be desirable for this and other reasons to make the calculations for a much larger number of sections than we shall probably actually employ.

We now proceed to consider in what way the principles which we have sought to establish may best be applied. The following scheme is an attempt to determine the most probable value of the thermal currents in the distribution of electricity upon a large scale as the problem will usually be presented in practice. We need only describe in detail the method employed to find N. This will involve all the data for M (so far as these quantities are capable of being ascertained).

Now the whole of the lamps supplied from any lighting station may obviously be placed in one of two divisions according to whether their period of burning is (1) regular or (2) irregular.

Among the "regular" lamps we shall include all those whose usage is in any sense periodic, whether or not they are in daily use. This division may again be separated into two main groups,

Group I., containing all lamps which are lit *at dusk* and extinguished either at dawn or at any hour which can be approximately assigned;

Group II., containing lamps which, although in regular use, are not *always* lit at the hour of dusk.

We shall find it necessary later to further subdivide each of these groups, but for the present we may leave them intact. It will be evident that Group I. includes all street lamps, very nearly all those in shops, warehouses, offices, clubs, railway stations, &c., and probably a very considerable proportion of those in private houses. Group II. consists principally of those in places of worship, halls, theatres, and similar public buildings. The "irregular" division contains all remaining lamps (apparently *chiefly* in dwelling houses) for which it is not possible to assign any approximately periodic or constant usage. It is evident that even if in any case the "irregular" lamps form a numerically large class, yet by far the larger share of the total work will be performed by the 1st division. It is therefore worth while to work out the probable thermal current for this division with as much accuracy as possible.

Division I.—"Regular" Lamps.

We have first to decide how we shall take account of the variation in the number of lamps alight due to the time of the day, the day of the week, and the period of the year. Now, we know that the total annual period from sunrise to sunset is the same on all parts of the surface of the earth, except where modified by local physiographical or topographical features. It follows that the (normal) mean annual night is everywhere twelve hours long, and we may take it to last from 6 p.m. to 6 a.m. (local time).

Group I.

It follows that for Group I., in which the lamps are lit at dusk, we shall be able, for the purpose of this particular calculation, to consider the hour of lighting to be 6 p.m. all the year round. This will give us the same number of lamp-hours (whatever may be the hour assigned for their extinction) as if we reckoned from the true hour of sunset day by day. This statement, however, requires one obvious qualification: clearly, if there are any lamps which in winter-time are lit at dusk and are extinguished before 6 p.m., they will be excluded from this reckoning. We shall therefore have to form a sub-group (which we will distinguish as Group Ia.) for these lamps; and, when necessary, we must make a separate calculation for them by a method which will be afterwards dealt with.

Having thus determined the normal hour of lighting for these lamps, we shall have to ascertain the usual hour of extinction in each case from the individual consumers. This ought not to be a matter of much difficulty. In order that we may see clearly the nature and extent of the information required, it may be worth while to sketch out a form of circular which might be issued for this purpose.* Omitting the necessary preamble, we might proceed to ask the following questions:—

(1) What is the total number of lamps required on your premises?

(2) How many of these are lit, as a general rule, at dusk?

(3) At what time (approximately) are they usually extinguished?

(*Specimen answer*) 6 at 8:30 p.m., 4 at 10 p.m., 2 at 11:30 p.m.

(4) If answers (2) and (3) do not apply to each day of the week, please state the exceptions.

(*Specimen answer*) On Saturdays 10 lamps burn until 10:30 p.m., and the other 2 until 12 p.m. On Sundays 6 lamps only burn until about 11:30 p.m.

(5) With regard to those lamps, if any, which you do not usually light at dusk, any approximate information as to their use will be esteemed.

Having obtained this information and summarised it (for each section of the cable separately), we shall be in a position to calculate the probable value of the thermal current. From what has been said before, it will be understood that any lamps burning till dawn are reckoned as being extinguished at 6 a.m.

In the first instance we have equation (4)—

$$N = \sqrt{\left\{ \frac{n_1^2 t_1 + n_2^2 t_2 + \ . \ . \ . \ .}{T} \right\}}$$

It will probably be deemed sufficiently accurate (at least for our present purpose of illustration) if we make the periods t_1, t_2, . . . each equal to one half-hour. The formula then becomes

$$N = \sqrt{\left\{ \frac{n_1^2 + n_2^2 + \ . \ . \ . \ .}{2\,T} \right\}} \quad . \ . \quad (21a)$$

where n_1 is the total number of lamps (in this group) burning during the interval from 6 p.m. to 6:30 p.m., n_2 is the number burning from 6:30 to 7 p.m., and so on. But as it stands at present this formula takes no account of variations due to the day of the week. We will suppose that the group presents a well-defined variation in the numbers both for Saturday and for Sunday. We shall now have to make, in effect, three sub-

* It is obviously desirable that this circular should be issued in the months of December or January.

Digitized by Google

divisions of Group I. And although it is true that we shall here count many, or perhaps all, of the lamps over again in each sub-division, yet it will be obvious that this is equivalent to the case in which we have two or more distinct sets of lamps *which are never run contemporaneously.*

We will indicate the values of N in Group I. for week-days by N_1, for Saturdays only by N_1', and for Sundays only by N_1''.

We shall then have for N_1 (five days per week),

$$N_1 = \sqrt{\left\{ \frac{5\,(n_1^2 + n_2^2 + \ldots)}{7 \times 2\,T} \right\}} \quad \ldots \quad (22)$$

But it will generally be more convenient to make the period annual instead of weekly, as we can then readily take account of the six annual holidays, or of any similar variation. Putting $(365{\cdot}25\ T) = Q = 8{,}766$, the number of hours in one year, we shall have

$$N_1 = \sqrt{\left\{ \frac{d_1\,(n_1^2 + n_2^2 + \ldots)}{2\,Q} \right\}} \quad \ldots \quad (23)$$

and, similarly,

$$N_1' = \sqrt{\left\{ \frac{d_1'\,(n_1^2 + n_2^2 + \ldots)}{2\,Q} \right\}} \quad \ldots \quad (24)$$

$$N_1'' = \sqrt{\left\{ \frac{d_1''\,(n_1^2 + n_2^2 + \ldots)}{2\,Q} \right\}} \quad \ldots \quad (25)$$

in which d_1, d_1', and d_1'' represent respectively the number of days *per annum* for which each sub-division is to be counted. The values of n_1, n_2, ... of course will differ in the three formulæ, but it has not been thought necessary to employ any distinguishing mark.

In order to obtain the values of the enumerators it is convenient to prepare a table in which to set out the values of n_1, n_2, ... and their squares. A separate table will of course be required for each sub-division.

The following is given as a specimen. To save space, it is supposed that all the lamps are extinguished by 9 p.m., save some which burn till dawn.

SPECIMEN TABLE.

"Regular" Division—Group I.

(Cable x, Section y) N_1 (5 days per week) $d_1 = 255$, $\mu_1 = 360$.

A.	B.	C.	D.	E.
	p.m.			
1	6:30	40	360	129,600
2	7: 0	60	320	102,400
3	7:30	0	260	67,600
4	8: 0	20	260	67,600
5	8:30	100	240	57,600
6	9: 0	40	140	19,600
...	...	0	100	...
...	...	0	...	...
	a.m.			
24	6: 0	100	100	180,000
		Total		624,400

Column A gives the subscripts of n.

„ B gives the time of expiration of the corresponding half hour.

„ C is obtained from the summary relating to this particular section, prepared from the replies to the circular, and gives the number of lamps *extinguished* at the end of each half-hour.

„ D gives the number of lamps *left burning* during each such period.

„ E gives the squares of the preceding column.

μ_1 is here the number of lamps in the group, not the total number on the section (which we write μ). It is therefore evident that the first number in column D will always be μ_1, and the other numbers are obtained by successively subtracting the numbers in column C. In this case by means of formula (23) we shall obtain $N_1 = 93$.

It may conduce to clearness if we here re-state what is implied by this result. We find, then, that if upon this section 93 lamps burn night and day all the year round, the same amount of energy would be wasted in the conductor as is actually wasted by the 360 lamps which each burn so many hours in the day on 255 days per annum *only.* d_1 was put equal to 255 by omitting Saturdays, Sundays, and six holidays.

The values of N_1' and N_1'' having been found in the same way, we proceed, before collating these three terms, to complete the calculation of the other groups for the same section.

(To be continued.)

THE ELECTRICAL CONDUCTIVITY OF CARBON COMPOUNDS.

Conductivity has been measured by interposing small thicknesses of the solid or liquid to be tested in the circuit of a battery composed of 400 zinc and chromic acid cells. In the case of liquids, it was also determined by observing the rate of change of potential of a metallic ball immersed in the liquid. The results obtained were as follow:—All solid carbon-compounds are non-conductors if measured at some distance below their melting point. All hydro-carbons and their chlorine, bromine, iodine, or cyanogen derivatives, ethers, and ethereal salts are non-conductors when in the liquid state. Water, alcohols, acetone, aldehydes, acids, anhydrides, quinones, phenols, and amines and their derivatives containing negative radicles show unmistakable signs of conductivity. The conductivity decreases with the increase in complexity of the molecule. Conductors, when dissolved in non-conducting media, form conducting solutions. Non-conducting liquids do not become conductors when heated, but the conductivity of conductors is increased by heat.

THE PHILADELPHIA EXHIBITION, 1884.*

(Continued from page 106.)

REPORT OF EXAMINERS.—*Section VI.—Carbons.*

Section VI. had submitted to it for inspection and report the carbons from five exhibitors, viz.:—

The Brush Electric Company, the Wallace Carbon Company, the Boulton Carbon Company, the Buffalo Carbon Company, the Carré carbons, manufactured by Emile Levy, Paris, and exhibited by Messrs. J. W. Queen and Co.

Of these, the Brush, Wallace, and Boulton companies submitted plain and copper-coated carbons, the Buffalo Company a homogeneous carbon, both plain and copper-coated, and, in addition, a carbon with a core of pure graphite inserted in a sheathing of coke and a carbon with a vitrified coating, while Queen and Co. offered only the uncoated Carré carbons. It was determined to have chemical, physical, and mechanical studies made of these carbons, but the study of the physical characters, resistance, duration of burning in the lamp under different conditions of current, &c., was handed over to the Section on Arc Lights, whose chairman, Prof. William A. Anthony, agreed to take this part of the work. The chemical and mechanical study was apportioned out among the members of the section who now present this report, and included determinations of the percentage of carbon, hydrogen, and ash, with a qualitative examination of the chief constituents of the latter in the several plain or uncoated samples the amount of copper on the coated carbons, both absolutely by weight and relatively per unit of length; specific gravity determinations on the uncoated carbons, both with sections of the solid carbons of given length and with the pulverised material; and, lastly, a microscopical study of the structure of the carbon pencils, using for this purpose specially prepared thin cross sections. The aid of micro-photography was also availed of in this latter case for the proper illustration of the results.

1. *Determination of the Percentage Composition of the Uncoated Carbons* (Carbon, hydrogen, and ash).—This was undertaken by Prof. Samuel P. Sadtler, and was made to include five samples, viz., the plain Brush, Wallace, and Boulton carbons, the plain solid Buffalo carbon, and the Carré carbon. The Buffalo carbon with the graphite core was not analysed, as the agent of the company said that the sheathing was made exactly of the same materials and by the same methods as the solid carbon exhibited, while the pure graphite core had a sufficiently well-known composition. The greater part of a single pencil having been reduced to fine powder, the material for analysis was taken from this stock. The determinations were made by the methods of ultimate analysis, using an open

tube, three-fourths filled with granular cupric oxide, placing the weighed material in a platinum boat, and conducting over this a slow stream of oxygen. In this way, besides the carbon and hydrogen determinations, the ash could be accurately weighed, and a check established upon the whole. The results were as in Table I.

In looking at these figures, several points of interest at once present themselves. The Brush carbons have the smallest ash of the series. On account of their rather more open and porous structure, there is room for occluded air in this case, as the result shows. The Wallace carbons have the largest amount of ash of the series. The character of this ash will be noted further on by another member of the committee. This carbon is closer in structure than the Brush carbon, being made in an entirely different way, and there is no occluded air to look for. The Boulton carbons, though having a higher percentage of ash than the Brush carbons, have a higher carbon and a lower hydrogen percentage, possibly having been burned at a higher temperature. The Buffalo carbons show a distinctly higher percentage of ash than the Brush or the Boulton carbons. The hydrogen percentage as given is possibly a little too high, as the summing up seems to show. The Carré carbons show a large ash, although considerably less than the Wallace carbons. The porous structure of these hydrocarbons offers, no doubt, a partial explanation for the relatively large percentage of occluded air and loss.

2. *Determination of the Percentage of Ash and Qualitative Examination of same.*—This was undertaken by Dr. Charles B. Dudley, and the examination was made upon a portion of the same pulverised material as that used by Prof. Sadtler in the combustion analyses. The results were as follows :—

The Brush carbons yielded 0·478 per cent. of ash. A qualitative examination showed that the portion insoluble in acids was slight ; that there was a considerable amount of ferric oxide and a trace of magnesia. The Wallace carbons yielded 2·672 per cent. of ash. A qualitative examination showed a large insoluble residue and a large amount of the oxides of copper and iron. The Boulton carbons yielded 0·892 per cent. of ash. A qualitative examination showed a small insoluble residue only, a large amount of ferric oxide and a trace of magnesia. The Buffalo carbons yielded 1·104 per cent. of ash. A qualitative examination showed a small insoluble residue, much ferric oxide, and a trace of magnesia. The Carré carbons yielded 2·086 per cent. of ash. A qualitative examination showed considerable insoluble residue, much ferric oxide, and considerable lime.

It will be seen that these ash determinations correspond quite generally, in some cases with great exactness, to those gotten in connection with the combustion analyses of the carbons.

Sample.	Length of coating.	Copper on length of 4 c. m.	Copper per centimetre.	Total copper (not including that on end).

3. *Determination of Copper on the Copper-coated Carbons.*—These were made by Prof. Wm. H. Greene, upon the samples of the Brush Company, the Wallace Company, the Boulton Company, and both the homogeneous and graphite-core carbon of the Buffalo Company. No copper-coated sample of the Carré carbon was exhibited. The results are given in tabular form in Table I.

4. *Specific Gravity Determinations.*—These are undertaken by A. E. Outerbridge, Jr., and were made upon the uncoated carbons of the Brush, Wallace and Boulton Companies, the French Carré carbon, and the plain, the graphite-core, and a glazed carbon of the Buffalo Company. A superficial examination of these carbons showed that some of them were much more porous and of coarser grain than others ; it was thought advisable, therefore, to make two different determinations of each sample, one for the purpose of ascertaining the specific gravity of the pencil, and the other the specific gravity of the material of which the pencil is composed. For the first method the samples were all cut to the same length, viz., 5 centimetres. These were first heated to a moderate temperature to expel the moisture absorbed in their pores and further dried in a desiccator ; when quite cool they were weighed upon a delicate analytical balance, sensitive to less than one-tenth of a milligram. The pencil was then coated with shellac varnish to prevent the absorption of water when immersed. When the thin coating of shellac was hard the sample was suspended from the beam by a filament of silk and reweighed ; this was the weight used in the specific gravity determinations. The sample was then immersed in a beaker glass of distilled water at 60° F. and weighed. The specific gravity of the pencil was then determined by the usual calculation. In order to determine the specific gravity of the material of which the pencils are composed, it was first ground to a fine powder in a steel mortar, put through a "No. 80" sieve, warmed to expel moisture, dried in the desiccator and weighed. The weight taken in this case was usually two grammes. The specific gravity bottle which was used in these determinations was filled each time with distilled water at, or very near, 60° F., and weighed ; the water was then poured out, the powder put in, the bottle refilled with water (care being taken that no air-bubbles remained) and reweighed ; from which data the specific gravity of the sample was determined.

(To be continued.)

ON THE ELECTRIC RESISTANCE OF A NEW ALLOY NAMED PLATINOID.*

BY J. T. BOTTOMLEY, M.A., F.R.S.E.

In the course of a series of experiments on the electric resistance of various metals and alloys, and in particular on the variation of the electric resistance of these metals and alloys with temperature, the author has examined a new alloy (called by the inventor "platinoid"), which has turned out to have important properties. This alloy is the invention of Mr. F. W. Martino, of Sheffield, who kindly supplied specimens of the metal, and wires specially drawn down to the finer gauges for experiments. Platinoid is practically German silver with the addition of a small percentage (1 or 2 per cent.) of metallic tungsten. The tungsten is added in the form of phosphide of tungsten, a considerable percentage of which is in the first place fused with a portion of the copper. The nickel is then added, and then the zinc and the remainder of the copper. The mixture requires to be re-fused more than once, and during the process the phosphorus and a considerable portion of the tungsten originally added are removed as scoriæ. In the end there is obtained a beautiful white alloy, which is platinoid. When polished the alloy is scarcely distinguishable in appearance from silver. To test the quality claimed for it as to being untarnishable, the author has been keeping ornamental specimens lying exposed to the ordinary town atmosphere ; and has satisfied himself that the alloy has a very remarkable power of resisting the tarnishing influence of the air of a large town. It is, however, the electric resistance of platinoid that has chiefly interested the author. German silver wire has proved of great use in the construction of galvanometer coils and resistance coils, on account of two important properties, viz., its very high resistance and the smallness of the variation of its resistance with change of temperature. Both those properties are possessed in a still higher degree by platinoid alloy. The resistance of German silver differs considerably in different specimens. It is commonly stated to be $21{\cdot}17 \times 10^{-6}$ B.A. ohms between opposite faces of a centimetre cube at 0° C. ;† or, reducing to legal ohms, $20{\cdot}935 \times 10^{-6}$ legal ohms between the opposite faces of a centimetre cube. Table A on next page shows the resistance of a number of specimens of platinoid wire :

It appears from these results that the specific resistance of platinoid is about *one and a half* times that of German silver. The experiments on the variation of resistance of platinoid with temperature were carried on in the following way :—The specimen of platinoid to be tested was wound on a wooden bobbin, on the surface of which a screw had been cut, and the spires of the helix were kept separate by lying between the threads of the screw. This coil was immersed in a bath of oil, and was connected in series with a known wire of German silver, the temperature of which was kept constant, and with a single Daniell's cell. The differences of potential between the two ends of the platinoid wire and the two ends of the German silver wire were determined by applying the electrodes of a high-resistance

* Paper read at the Royal Society, May 7th ; note added May 12th.

† Given by Prof. Fleeming Jenkin, F.R.S., as expressing the results of Matthiessen's experiments.

Digitized by Google

galvanometer. The ratio of the differences of potential is the same as the ratio of the resistances of the two wires.

TABLE A.

Specifying Number.	Diameter in decimals of centimetre.	Cross Sections.	Resist. legal ohms per metre.	Resist. between opposite faces of centimetre cube legal ohms.
16	·1610	·0204300	·181	$36·98 \times 10^{-6}$
17	·1430	·0160200	·202	32·36
18	·1230	·0119400	·288	34·38
19	·1110	·0096770	·353	34·16
20	·0865	·0058760	·555	32·61
A	·0595	·0027180	1·250	$34·76 \times 10^{-6}$
B	·0495	·0019240	1·707	32·85
28	·0402	·0012690	2·605	33·06
29	·0340	·0009070	3·412	30·94
32	·0290	·0006605	4·371	28·87
36	·0220	·0003801	8·219	31·24

In the following table is shown the ratio of the resistances of a specimen of platinoid wire at different temperatures to its resistance at zero. The wire used was the same as that specified as No. 20 in the table of resistances. The length of the wire experimented on was about four-fifths of a metre. The only trouble in the experiment was the keeping the oil-bath, which was filled with linseed oil, thoroughly stirred, and of uniform temperature throughout.

Temperature.	*Resistance.
0°	1·0
10	1·0024
20	1·0044
30	1·0075
40	1·0066
50	1·0097
60	1·0126
70	1·0134
80	1·0166
90	1·0188
100	1·0209

* The Resistance at 0° C. being = 1.

This gives for the average percentage variation of resistance per 1° C., between the temperatures 0° C. and 100° C., the number 0·02087. A second wire tested very carefully in a similar way gave for this average percentage variation between 0° and 100°, 0·022 per degree, with a steadily increasing rate of variation from the beginning. To compare this increase in resistance due to increase of temperature with that observed in other metals and alloys, we find that the percentage increase of resistance for 1° C. at 20° C. for copper is 0·388, platinum-silver alloy 0·031, gold silver alloy 0·065, and for German silver 0·044. These numbers were obtained by Matthiessen in the course of his experiments for finding a suitable metal or alloy for the purpose of constructing the British Association standards of electric resistance. It appears that the variation of resistance of platinoid with temperature is very much smaller than the smallest observed for any of the metals and alloys then examined. The modulus of rigidity, the Young's modulus (or modulus for elastic longitudinal extension), and the breaking weight for platinoid wire were also determined. The wire used was a portion of that marked A in the foregoing table. This wire is a little larger than No. 24 of the Board of Trade standard wire gauge, and has a diameter of 0·0595cm. The rigidity modulus was found to be $4751·8 \times 10^6$ grammes weight per square centimetre. The Young's modulus is $1222·4 \times 10^6$ grammes weight per square centimetre. The breaking weight is about $6·029 \times 10^6$ grammes weight per square centimetre. The specific gravity of platinoid wire has also been found by the author to be 8·78 compared with water at 20° C. Platinoid when drawn hard is softened, like copper, by heating and sudden cooling.

COMPANIES' MEETINGS.

The West Coast of America Telegraph Company (Limited).

The eighth ordinary general meeting of the shareholders of this Company was held on Wednesday, the 24th inst., at the Cannon-street Hotel, under the presidency of Mr. Robinson Kendal.

The SECRETARY (Mr. Fred L. Robinson) read the notice convening the meeting, together with the minutes of the previous meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: If I were a tractable man, or if I were inclined to follow my doctor's peremptory advice, I should not have been here, but should have been inhaling the deep sea breezes. I have now the pleasure, gentlemen, to move the adoption of the balance-sheet and the report, which show that the gross revenue for the year ending the 31st December last amounted to the sum of £52,011. 10s. 7d., leaving a net balance, after paying debenture interest and all other charges, of £14,523. 15s. 6d., a result which, as the report says, is as satisfactory, all things considered, as could have been looked for, and which has enabled the Directors to commence the regular payment of dividends to the shareholders, and to place the Company, by the creation of the reserve fund, in a much stronger and more healthy financial condition. The report enters so fully into the position of the Company, and so clearly explains everything, that there is little left for me to do at this moment beyond recapitulating what is therein said and what has been read, I suppose, by every shareholder. Up to this time dividends on the ordinary shares have been paid so soon as the finances of the Company admitted of their payment, but the Board think the time has now come to equalise the dividends so far as practicable, and to make them payable half yearly. As you will see by the balance-sheet the sum of £18,000 altogether was paid in dividends last year on the ordinary shares, and a sum of £10,000 was placed to reserve, leaving a balance of £3,349. 1s. 3d. Out of this balance the Board recommend that a final dividend be declared of two shillings per share, with a further interim dividend, out of the net income for the current half year, of two shillings per share, making a dividend of four shillings per share, or a total sum of £6,000. This, I take it, though not so satisfactory as we could wish or desire, is yet far from unsatisfactory considering the drawbacks and difficulties we have had to struggle against in the shape of a deplorable and disastrous war and a necessarily consequent paralysed state of industry and commerce. Our advices from the "West" Coast say that trade is now at its worst, that it cannot well be worse, and that any change at all must be for the better. Now I am not disposed to prophecy or to indulge in predictions as to the future of trade upon the coast or as to the future of our business, but I may point out that, notwithstanding the severe depression in trade, and the universal complaint of the badness of the times, we, as a Company, have nothing to complain of so far this year, but we have something to hope for in the not impossible event of the restoration of peace and the revival of trade over the entire coast. Our receipts so far have not fallen off more than some £900, whilst our expenditure we know has decreased, owing to our cables having been kept in the highest state of efficiency, and owing to the services of our repairing steamer not having been required for even a trifling repair since the beginning of the year. Should peace be restored, and should trade revive—and the newspapers will have informed you of the encouraging hopes in this regard recently to hand—we ought to be the first to benefit by the changed condition of things, for we must not forget, whether trade be good or bad, that we are the possessors of a splendid cable system in as good order and as perfect a condition as it was when it was laid down, extending for some 1,700 miles down the great coasts of Peru and Chili, where many Englishmen before now have realised large fortunes, and where trade and commerce have been in times not long past as active and as profitable as in any part of the world. The Company has had reverses and difficulties of no ordinary character to overcome and to pull through; but these are, I am hopeful enough to believe, all over, and the Company is, it may now be said, moored in comparatively smooth water. Four years since the Company owed to creditors some £26,000, with its cables cut and its trade destroyed, and with little or no hope of seeing how that £26,000 was to be provided for, or its payment postponed. It was provided for, however, and paid off, and not only has this amount been paid off, but we have since that time paid in debenture interest a sum of £48,000, with a further sum, including the amount we propose to pay to-day, of £24,000 interest upon the ordinary shares; whilst beyond this we have placed £10,000 to a reserve account, and, perhaps what is better than even all this, we have to-day at our bankers a further hard cash balance of some £14,000. I beg leave to move the adoption of the balance-sheet and report.

Mr. THOS. FIELDEN CAMPBELL seconded the motion.

The CHAIRMAN, in answer to a shareholder, said that they proposed paying a dividend every half year for the future. He hoped when they met next they should be able to state positively that peace had been declared on the coast of Chili and Peru, and that there was some hope of that trade reviving which for a long time had brought so much profit to English traders in that part of the world.

The motion was agreed to.

Subsequently the retiring Directors, Mr. Thos. F. Campbell and Mr. W. E. M'Andrew, were re-elected to their seats at the Board.

Mr. J. Weise, of Messrs. Turquand, Youngs and Co., was also reappointed auditor, a vote of thanks to Mr. Kendal for presiding terminating the proceedings.

United Telephone Company (Limited).

The annual general meeting of the shareholders in this Company was held at the Cannon-street Hotel on the 25th inst., under the presidency of Mr. James Brand.

The SECRETARY (Mr. Blaikie) read the notice convening the meeting, and

The CHAIRMAN said: Gentlemen, I hope you will agree with me that the report shows a satisfactory result, and that our five years of very hard and anxious labour and earnest attention to your affairs have now been attended with a fair amount of success. This last year you will notice we spent on capital account on the London system about £20,000. Our revenue has increased by about £10,000, and our working expenses by something like £600. We have written off the large sum of over £13,800 for depreciation of wires and plant in London and instruments in use in the provinces and all over Great Britain and Ireland. This makes in all between £48,000 and £49,000. We are still, I am sorry to say, without exact data which would enable us to form an entire conclusion as to the right figures at which we are to estimate this depreciation, but we have tried to provide more than is necessary

Digitized by Google

rather than less for this purpose. In addition to this maintenance and renewal of wires, which is going on more or less every day—for we are in the course of our business maintaining and renewing wires every day, which is provided for out of the revenue—there is this sum written off for depreciation. Besides this the reserve fund is over £65,000, and this we propose to increase by £10,000, so that will make over £76,000 to the reserve account. Therefore, what with the maintenance and renewal every day, the amount we write off for depreciation, and the amount we write off for reserve, I think, as far as our plant and system in London are concerned, we have sufficiently provided for eventualities. We are somewhat disappointed—and perhaps some of you will be, too—that our progress in London and the suburbs has not been greater. The increase we show is, however, a net increase, and covers the withdrawals, and those withdrawals during the past year have been rather frequent, the majority, I am sorry to say, being owing to the hard times through which we have been passing. I have an analysis of the number of withdrawals, and they are about 300, and if any of you would like to know the exact causes of the withdrawals I shall be glad to tell you. I am glad to say that not a very great proportion has arisen from dissatisfaction, but most of them are from people who have been unfortunate in business, while some have been from people removing their counting houses and not requiring the thing any longer. I may also mention, to account for the reason why our progress has not gone on by leaps and bounds, as was thought would be the case, our business for some months last year was checked by the offer of another company to connect exchange subscribers at lower rates. We are also unable as yet to avail ourselves of the full benefit of the extension of the radius and the liberal terms granted by the Postmaster-General. Before we can commence and fully take advantage of the good things obtained for us in Parliament from the Postmaster-General, we have to do a great deal of work which is for the time unseen, and the value of which cannot be estimated till everything is completed and the result is shown by further subscribers. We have to construct long trunk lines, to canvass very great districts, obtain way-leaves, and do similar very arduous work. This is all now in full progress; but we cannot show you what the result is until it is quite completed, and all those districts are connected with our central exchange. To give you some idea of what has been done I may tell you that we have erected an exchange at Brighton, which works admirably. To-day or to-morrow Clapham and Kilburn will have call rooms attached to our central system. South Kensington was opened the other day. Our eastern exchanges accommodate the whole of the dock system. The telegraph department of the General Post Office has been connected with our central exchange, and in a few days subscribers will be able to speak their messages direct from their offices to the central telegraph room, which will save much time and trouble, and they will be also able to receive any messages sent to them in the same manner. We have also an exchange at the Inventions Exhibition, and we have thirty-four exchange subscribers. We are pushing forth new routes from the city to Chiswick, Kew, Battersea, and Brentford. The wire is run to Sydenham, and will be connected in a few days. I think that will show you that at any rate we are using every endeavour in our power to push forward your business as rapidly as possible. I do not think I need say more about our relations with the Post Office than I have said in the report; I have every reason to hope that they will continue such as to facilitate the extension of your business. With regard to litigation, what we have had hitherto has been forced upon us. We have, I am glad to say, proved to be in the right in every case, and in future the best thing I can say is that we hope to have as little litigation as possible, and much less than in the past. When we last met we were involved in competition with the Globe Company. We felt that though the legal question between us would in the end be decided in our favour, yet this favourable decision must be a matter of time, and in the meantime they were giving us a great deal of trouble in many ways, though we knew that the business they were conducting was not at a profit. Therefore, when they approached us with an offer to sell their stock of instruments, plant, and way-leaves, and, in fact, their whole undertaking, including the patents on which they relied, we thought it was in your interest that we should buy them up; and we think, on the whole, that we did wisely. I do not propose to say more on that subject unless anyone asks any questions. As to our Bill in Parliament, we had promoted a Bill in Parliament for the regulation of overhead wires, and putting the overhead wires under some sort of authority, which we could appeal to in case of dispute between ourselves and any of the authorities or private persons who objected to grant us facilities. We promoted this Bill to a certain extent, and then we found that the Government would not allow us to bring in a Bill on our own account, and they promised to legislate on the subject. The whole matter has been submitted to the House of Commons, and has been thoroughly threshed out, and a Select Committee has come to certain conclusions, which I suppose, by and by, will more or less become law. In the meantime I think a good deal of the public feeling which had been created against overhead wires is subsiding, so many people having found—and finding this from daily use—what a very valuable adjunct, both to public business and commerce and their private comfort in their houses, the telephone has become. Every one who becomes a subscriber and uses the telephone is most anxious to help us in way-leaves, and in this matter we are going on as well as this very difficult question will allow us. We have dropped our own Bill, and are relying on the recommendations of the Committee of the House of Commons; and we expect we shall at any rate know to whom to apply in case of any trouble in pursuing our business. The only matter I have now to speak of is in paragraph 9, and I will read that:—"The formation of a separate company for the metropolitan district having been suggested to the Board, the notice of the meeting has been framed so as to confer the necessary powers upon them, if they should consider it desirable, to proceed with the matter upon such terms and conditions as they feel they could properly submit to the shareholders at the special meeting which it would be necessary to call for that purpose." The words in the paragraph I think will do away with any apprehension that was aroused in certain quarters. I had a few letters myself on the subject about the issue of proxies for our meeting. I can assure you on my behalf that that issue was entirely a clerical error, and we had no wish or intention of pledging the shareholders to any course at all. In a matter so vital to all of us we should not think of entering into negotiations for the sale of our London system without letting you into our full confidence. If there is any misapprehenion as to these proxies I will take the blame on myself, and it will not be done again. As regards this Company, the way this matter came about was this. It has been thought by ourselves sometimes and by some of our shareholders that we do not develop as quickly as we might [hear, hear]. Well, I do not object to that "Hear, hear," because I very often think so myself, but I have been at this work since the very beginning of the whole business. I happened to be the first man almost in communication with Prof. Bell as to the sale of the Bell patents, which were the beginning of our business, and I have passed through it as well as I can with the assistance of the other members of the Board. I have, therefore, seen the enormous difficulties that we have had to surmount. It is a new thing, and we have to be very particular about treading on anyone's toes; the railways cannot give us trunk lines, the Post Office has interfered with us, and so forth. The thing has been full of difficulties, and though I am inclined to think that we do not go on fast enough (and I hope we shall go on faster), yet I know the enormous difficulties that we have had to contend with, and which will have to be contended with by any society who wishes to go on faster. Having these feelings, we listened to some of the suggestions made for the sake of dividing our business. We thought that our patents, the large interest we have now in shares of subsiduary companies, and the looking after infringers of our patents, might be kept under the head of the United Telephone Company, and that we might place the business in London and the suburbs under an entirely new organisation, assisted by our staff and so forth. Certain terms were proposed, and we thought they did not seem unreasonable, and we went up to a certain point in the negotiations. Certain gentlemen had promised to join the Board, and very good men they were, but when we came to discuss the matter with our solicitors, we found, putting aside the question of price, that we should be confronted under certain paragraphs in our Articles of Association, and our agreements with our subsiduary companies, with a state of things that might and probably would land us in a sea of legal difficulties, which it would be very difficult to foresee the end of. We thought, therefore, that on the whole we were not ripe to bring before you a scheme to-day which we could entirely recommend to your approval. We were also guided somewhat in this decision by certain words used to me and my colleagues, and letters I received asking us to bear in mind, now that we had overcome so many difficulties both with the public and the authorities of the Post Office, that we were landed, as was shown by our report, in a position of considerable comparative comfort and prosperity, and that now that the great difficulties had been overcome in the initiation of the enterprise, and had been overcome successfully, if any good was to be got out of a new organisation and business, it should be given to the Company. That view always appealed to us very much, and at any rate, as we learned when initiated into Masonry, we were taught caution; and we thought that before approaching you with any definite proposal we should at least realise to ourselves exactly what difficulties and responsibilities we were going to incur, and possibly search out some scheme which, while organising your business in another way, would enable us perhaps to realise those hopes which are entertained by many of you and ourselves, and retain that profit which we should necessarily have to part with in selling this part of the undertaking to any other company away from ourselves. I do not know that we should say any more on that subject to-day. I do not know that we have made up our minds that it would be wise to sell this part of our business to a separate organisation, but if we pursue the matter further we shall summon a special meeting and tell you all about it. He concluded by formally moving the adoption of the report and accounts, and the declaration of a dividend of 7s. 6d. per fully-paid £5 share (part-paid shares receiving in proportion) for the second half year, ended 30th April, 1885, making a total dividend of 10 per cent. for the year.

The DEPUTY-CHAIRMAN (Mr. James S. Forbes) seconded the motion.

Mr. LEYLAND said he had no doubt that the Directors had good reasons for asking for the powers which they did, but the notice had come very unexpectedly on the shareholders, and had created a good deal of excitement; but he thought that this matter had been pretty well explained in the report, which, however, had come out rather late in the day. He considered that the report and accounts ought to be in the hands of the shareholders at least a week before they came to consider them. He was very glad to hear what the Chairman said as to the development of the business. He did not think it was good policy to spur a willing horse, but seeing that they had only six years more to run with their patents, when they would be open to the world, he considered that their true policy was to develop their business in that period to the utmost. He observed an asset of £654,000 in shares of subsidiary companies, and obviously that was at the very backbone of the success of the Company. They seemed to derive in royalties very much the same amount as from the balance of revenue account; and he presumed that the great bulk of the royalties came from the subsidiary companies. He trusted that the Directors looked after the power they had of appointing Directors on the Boards of these companies. As to the negotiations which had gone on for the sale of a portion of their business, he thought it would be better in all respects for them to keep it in their own hands, and, if necessary, make some re-arrangement of their organisation, so as to meet their requirements. Looking over the Articles of Association, he found that

Digitized by Google

the Directors, after a dividend of 10 per cent. had been paid, were entitled to a share of the surplus profits beyond. He did not at all object to the principle of paying by results, but he wished to know whether this deduction had been included in the accounts.

THE CHAIRMAN: No.

Mr. E. H. GALSWORTHY said that he had been astonished at receiving a proxy paper, but he thought they might be satisfied with the explanation given by the Chairman of this matter. He thought, with the previous speaker, that the accounts should be in the hands of the shareholders seven days before the meeting; and he would be glad to see the accounts made up to June and December, instead of April and October. On the face of the report he did not think it was a bad one. He wished to know what principle they had adopted in writing off £13,820 for depreciation. He quite approved of carrying a certain amount to the reserve fund, for in such a Company they ought to have a good reserve fund. He wished to know whether the 300 withdrawals were included in the 3,820 subscribers.

The CHAIRMAN replied that 300 was the net number.

Mr. GALSWORTHY hoped, if necessary, they would introduce another Bill to settle the question of overhead wires, if the matter was not dealt with by the Government. With regard to the idea of a district company they must feel very much obliged to the Chairman for what he had told them. He had been going to suggest that if the idea was to be pursued the Directors would take no step whatever till they had given full opportunity to the shareholders to consider the whole scheme and the terms upon which they suggested parting with the business. The difficulty of managing the Company was considerable, and he was not sure that the Directors would not have enough to do with looking after that part of the business to which the Chairman had alluded. He considered that if a new company were formed the shareholders in this Company should have the option of taking the shares. He thought it would be well if in the future the Directors gave the shareholders in the report some idea as to how the subsidiary companies were going on, when they would be able to form some idea of the value of that asset in the balance-sheet.

Mr. F. J. BLADON held that it was only in fostering subsidiary companies that they could realise their goodwill, but at the same time he thought the Board was thoroughly capable of developing the metropolitan business in a manner most to the advantage of the Company. He thought they should give up all idea of parting with this branch of the business.

Mr. SICHEL said that the results set out in the report showed the zeal and ability with which the affairs of the Company had been conducted by the Directors. With regard to issuing the capital of a new company (if it were brought out) to the shareholders of the present Company, there were several difficulties in the way of doing so by the rules of the Stock Exchange. The Stock Exchange would not consider such a subscription an open one, and would not grant an official quotation. Apart from that, however, he knew that there was a very general opinion that the sale of the backbone of the undertaking, although it might be a wise proceeding for the moment, could not be so ultimately, and must cause loss in the future. He threw out the suggestion whether the addition of one or two members to the Board, to take the special management of new subscriptions, would not give them all they could expect from a second Board and a new organisation. The business could be enormously developed at the West End, where there were immense blocks of properties, to the occupants of which the telephone would be of essential use, and they might be induced to become subscribers on the Company giving them some reduction. He did not know whether these people might not be canvassed, the work being paid for by commission.

The CHAIRMAN: I think I may begin by saying that, after the unanimous expression of feeling by the meeting—which, as I said, is a good deal concurred in by your Board—we will drop the idea of the metropolitan company. But we have had it in our minds for some time to have some division of the business of the Company inside, which we hope will, before we meet next year, produce better results than are before you to-day. I am very much obliged to Mr. Sichel for his really very valuable suggestions, and I do not want to take away from the value of them by saying that they have been considered very much by ourselves. The difficulties, however, have been so great that we have not seen our way to carry out what we require to the fullest extent, but by this subdivision of our business we hope this very matter will be carried out. Both Mr. Leyland and Mr. Galsworthy suggest that the Directors should publish the accounts for a longer time before the meeting. To that we fully agree, and we will take care that this is done in the future, and that they shall be published at least seven days before the meeting. As to the patents having only six years to run, we know that they will expire, but still we hope that we shall have so fully occupied the ground by that time that the dropping of the patents will not be so serious a matter. No doubt a great deal of our prosperity now (and it will be more so in the future) will depend on the way in which the subsidiary companies are managed, and we will adopt Mr. Galsworthy's suggestion and give you some information in our next report as to our position with them and the position of those companies themselves. Of course, when the royalties on our patents are over, that in a way will make our share in the profits of the subsidiary companies more valuable, because the new companies will then be free from the royalties. As to making up the accounts to June and December, I do not suppose the meeting care much about making the change now, and I think that is a matter that may be left for the present. With regard to the principle on which we charge depreciation, we arrive at that in a sort of rough and ready way. We take a varying percentage—about 15 to 20 per cent. on the wires, and 10 per cent. on the instruments. We have got a scale which we should be glad to show you if you like afterwards. The Post Office themselves have no trustworthy data in this matter. As to promoting another Bill in Parliament, we do not exactly know what the Government is going to do. We were very gratified by the decision come to by the Select Committee, and we hope that the Government will carry it out. If they do not, we shall of course have to think what we shall do. As Mr. Sichel pointed out, we should have had no difficulty in bringing this new company out if we could have offered the whole of the shares to our shareholders, and they had taken them up; but then we should not have got a quotation.

Mr. BLADON: You could have done it by an increase of capital.

The CHAIRMAN: Well, we have dropped the idea now. As to the Directors' remuneration, that is an important point [laughter]. All those present who are original shareholders will, I am perfectly certain, agree with me that your Board have earned honestly this extra remuneration, to which we are legally entitled. We have never sought to increase your dividend, of course with the view of making our percentage available or anything of the kind. This year we pay you 10 per cent., and we carry over a large sum more than last year. To tell you the truth we do think we are entitled to this, but we would prefer to leave the matter in the hands of the shareholders.

The DEPUTY CHAIRMAN, in reply to a question, said that, after paying the 10 per cent. dividend there remained to the credit of profit and loss £17,848, which included £5,000 odd brought from the previous year, when they did not pay 10 per cent. dividend. Therefore that £5,000 odd could not form a part of the sum on which the Board were entitled under the Articles of Association to take their percentage. What they were entitled to take upon was £12,787, and 20 per cent. upon that was £2,557. They would see this set out in clause 58 of the Articles of Association, which he read.

A resolution was passed, on the motion of Mr. LEYLAND, requesting the Directors to charge the percentage to which they were entitled,

Mr. GALSWORTHY, while agreeing to the proposal, observing that he did not think it should be taken as a precedent for the future, because the profits might become so very large, and to take 20 per cent. on the surplus over a 10 per cent. dividend would be unfair to the shareholders. He had been informed that there had been a great many transactions in the purchase and sale of shares by Directors of the Company. If that had really been so, he hoped the practice would cease.

Mr. BATTEN was re-elected to his seat at the Board, and the auditors, Messrs. Quilter, Ball, and Co., and Messrs. Price, Waterhouse, and Co., were also re-elected.

The proceedings terminated with a vote of thanks to the Chairman and Directors.

Business Notice.—The Pilsen Electric Light Company have removed their factory and offices to Edward-street, Hampstead-road, N.W.

NOTES.

PROGRESS IN AMERICA.—The city Council of Detroit decline to advertise for proposals to light the city with gas.

TRANSMISSION OF POWER.—It is said that Sr. A. Bertelli, of Brescia, has invented a new method for the transmission of power.

THE CHOLERA IN SPAIN.—A telegram from Madrid, dated Wednesday last, announces that all the telegraph clerks are ill of cholera.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th June amounted to £2,962.

THE ELECTRIC LIGHT AT PEKIN.—The Italian Minister at Pekin recently gave a ball, when the Embassy was lighted by a large number of incandescent lamps.

THE TELEGRAPH TO MERV.—A telegram from St. Petersburg, dated June 30th, announces the opening of telegraph offices at Karibent, Rukhnabad and Merv.

THE AUSTRALIAN COPPER TRADE.—During the past month the shipments of copper from the Australian ports were:—300 tons of copper ingots, and 300 tons of copper ore.

CHURCHES STRUCK BY LIGHTNING.—According to *Il Giorno* the parish church of Collebeato, near Brescia, and the Church of Santa Veneranda, in Mortara, have been seriously damaged by lightning.

NOTICE OF REPAIR.—The Eastern Telegraph Company announce the re-establishment of communication *vid* Suez with India, China, and the Far East by the repair of their Aden-Bombay cables.

CUT THE WIRE.—At the trial of Marchandon it was stated that before the robbery he had cut the electric wire in the apartment in order to prevent the Countess from calling for help should she awake.

THE ELECTRIC LIGHT ON A LEITH PASSENGER STEAMER.—The London and Edinburgh Shipping Company's fine saloon steamer "Iona," 676 tons register, has been fitted up throughout with the electric light.

LIGHTHOUSE ILLUMINANTS.—Sir James Douglas and several members of the Elder Brethren of the Trinity House are conducting a further series of experiments at the experimental lighthouses at the South Foreland.

OBITUARY.—The death is announced in France, on the 21st ult., of M. H. Tresca, membre de l'Institut, and vice-president of the Société Internationale des Electriciens. M. Tresca had arrived at the ripe age of seventy-one.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th June were £2,415, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—This company announce that the coupons, due on the 3rd inst., on the debentures of this company, will be paid by Messrs. Barclay, Bevan, and Co. The coupons must be left three clear days for examination.

THE ELECTRIC LIGHT FOR RESERVOIRS.—On the occasion of the re-opening of the Nottingham Park-row Reservoir recently the reservoir was lighted by five 2,000 candle-power arc lamps by Oppenheim Bros., of London, under the superintendence of Messrs. Bowman and Smith.

TELEGRAPH STATISTICS.—A Florentine publisher, who has been able to find complete postal statistics of the world down to 1883, has just issued them in book form. In that year there were in Europe 41,500 telegraph offices, and the number of telegrams transmitted amounted 117,000,000.

FREEMASONRY.—On Saturday, the 27th ult., the "Electric" Lodge held their second meeting, when Mr. Crookes was passed, and Messrs. J. E. Spagnoletti and W. H. Denny were initiated. Subsequently the members dined together, the usual loyal and masonic toasts being duly honoured.

BATTERY WITH TWO LIQUIDS.—M. Dupre has succeeded in suppressing the nitrous vapours of the Bunsen battery by using a depolarising liquid, consisting of nitric acid in which 75 grs. potassium dichromate have been dissolved per litre. In contact with the zinc he employs either acidulated water or potassium disulphate.

THE CANADIAN TELEGRAPHS.—The new telegraph line from Dunmore to MacLeod, in the Canadian North-West, is being worked. There are offices at MacLeod barracks and Lethbridge, and a telegraph line is to be constructed from Calgary to Edmonton, and another from Medicine Hat to some part of the international boundary.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of June was 3,715, estimated to produce £3,000, against 3,531 messages, producing £3,168, in the corresponding month of last year. The traffic receipts for the month of March, estimated at £3,500, realised £3,510.

SOCIAL.—The officers of the old telegraph companies held their annual dinner at the Salisbury Hotel, London, on Wednesday, the 24th June. Sir Charles Bright occupied the chair, and amongst the officers present were Messrs. Spagnoletti, E. Graves, Newman, Boys, Walsh, and Radcliffe. Mr. C. H. B. Patey, of the Post Office Department, was present as a guest.

MESSRS. KRUPP'S WORKS AT ESSEN.—The latest published report of the establishment of Messrs. Krupp, Essen, shows that at Essen alone railway tracks of a total length of 37 miles are laid down, with a rolling stock of 88 locomotives, 893 waggons, 191 trollies, besides 69 horses. There are 40 miles of telegraph wires, 35 telegraph stations, and 55 Morse apparatus.

THE ELECTRIC LIGHT IN MUNICH.—A recent number of the *Archiv für Hygiene* contains a valuable report by Dr. P. Renk, one of the instructors in the hygienic institute at Munich, upon the results of a series of observations made by him in the Royal Theatre at Munich, which has been recently fitted up with a system of electric lighting, including more than 1,400 Edison lamps actuated by six large dynamos.

PUBLIC LIGHTING OF LIEGE.—The Thomson-Houston Electric Co., of Boston, U.S.A., has, through the American Vice-Consul for Liége, made the following liberal proposition for lighting that city, viz., to illuminate gratuitously, for three months, all the streets, boulevards, avenues, &c., and if such lighting give general satisfaction, to give in a tender for the permanent lighting, in competition with the gas companies.

THE TELEPHONE AND FIRES.—On the occasion of a fire which broke out recently on the extensive premises of the British Xylonite Company in High-street, Homerton, the telephone rendered very valuable assistance in summoning additional engines. In regard to the recent outbreak at Whiteley's, we are requested to state that the Brigade were summoned by the Exchange Telegraph Company's fire alarms, the telephone being used to summon Captain Shaw.

THE SUBWAYS OF THE CITY.—During the course of the proceedings in connection with the annual meeting of the

Digitized by Google

Municipal Engineers the subways of the Holborn-viaduct and Snow-hill were visited, by permission of Lieut.-Colonel Haywood, the city engineer, and were found to be specially interesting—indeed, these remarkable subways, with their many lines of water pipes, gas pipes, and electric wires, are a portion of subterranean London which deserves to be more widely known and to be extensively imitated.

THE POST OFFICE TELEGRAPHS.—Some remarkable work was done on a quadruplex circuit during the Ascot races between the Central Telegraph Station and Ascot. On Monday, 2,325; Wednesday, 3,007; Thursday, 2,234; and Friday, 2,132 messages were sent, making a total of 9,698. The greater part of the work of each day was confined to three hours. On one day 1,691 messages were dealt with between noon and 3 p.m. In one hour 606 messages were signalled. The messages were of average length. Multiple address and press messages were counted as one message.

THE THUNDERSTORM IN PARIS.—During the recent thunderstorm in Paris the lightning fell at the Sceaux railway station, and set on fire the office of the under station-master, but the flames were soon extinguished. The Church of the Madeline received a violent discharge of electricity, which seems to have made itself felt all round the spot. At the same time, a newsvendor who sells journals in a kiosque was rendered nearly insensible, and a waiter in a coffee-house and a person passing the street were thrown down. The lightning seems to have entered a number of houses, but without causing any fatal or even severe accident.

ELECTRIC LIGHTING OF THE BRUSSELS-SCHAERBEEK STATION.—The arrangements for lighting the sidings at the new Schaerbeek Station, Brussels, are now complete. Eight double arc lamps, on the Gülcher system, which burn 16 hours without renewing the carbons, are mounted on iron trelliswork masts, 35 metres or 115ft. high; and any of them can be thrown in or out of circuit by means of switches in the engine room. The lamps are raised to the tops of the masts by a winch at each, the wire cords being protected by tubes. The dynamo is driven at 400 revolutions a minute by a 25 horse-power engine, provided with expansion gear variable by the governor.

NEW TELEPHONE EXCHANGES.—On June 26th the National Telephone Company opened their new Exchanges in Whitehaven and Workington, and a trunk wire between those towns. Most of the chief firms have become members, and on the opening day the traffic over the trunk wire, which is 8¾ miles long, was incessant, the average number of connections per subscriber at the close of the day amounting to over 5. This system is the nucleus of a general telephonic system for Cumberland. Trunk wires from Workington to Maryport, and from Whitehaven to Cleator Moor and Frizington have been commenced, and an Exchange in Carlisle will be opened about the end of July.

LIGHTING OF THE BRUSSELS HOTEL DE VILLE.—At the meeting of the Brussels Communal Council, on Monday last, the necessary funds were voted for electrically lighting the principal portions of the Hôtel de Ville. There were only two dissentients from the proposition, one of whom called upon the college not to be carried away by *electromania*, observing that the economical side of the electric lighting question had not advanced during the last two years. A supplementary engine is to be put down, which will be capable, if required, of replacing that which now drives the dynamo for lighting the Grand' Place. The specification for the Hotel de Ville installation is already prepared; and the work will shortly be let by public contract.

THE TELEPHONE IN MOROCCO.—For a long time past Señor Rotondo, the Spanish Vice-Consul, has been labouring to establish telephones in Tangier, and has been very desirous of forming an alliance with an English company. A French company from Algiers has set up in opposition to Señor Rotondo, and is establishing telephonic communications everywhere, which is a prelude to other projects. We are glad to see any improvement introduced by anybody whomsoever, but we should like to see the two united, and working harmoniously together. Señor Rotondo is certainly entitled to the best thanks of the inhabitants of Tangier for his untiring efforts to bring the telephones into use there.

RECENT INSTALLATIONS.—Messrs. J. D. F. Andrews and Co. have lately installed sixty-five 20-candle lamps at Messrs. R. and J. Dicks' boot warehouse at 296, High Holborn. This is the principal shop of twelve others in London belonging to these extensive gutta percha boot and shoe manufacturers. The premises consist of work shop, stores, fitting rooms, and sale shop, and the electric light is distributed throughout, being supplied with current from an Andrews A/4 dynamo going at 560 turns per minute, and driven by an eight horse Otto gas engine. The five electroliers in the shop are a new and pretty design, each having five lights with a switch in the centre. There are twelve lights in the window, which is an air-tight show case, and illustrates how universally the electric light can be applied. In the workshops the lights are fitted to universal jointed brackets and pendants of practical designs, each having its own switch.

THE PROPOSED ELECTRIC RAILWAY AT GREAT YARMOUTH.—The scheme of the electric railway has collapsed, says the Great Yarmouth *Independent*, so far as running it upon the Drive is concerned. The proposal was rejected by a majority of two, a result which would not have been achieved but for the absence of some of the members of the Lands Committee who were in favour of the scheme, and who probably absented themselves from the council meeting in the belief that the adoption of the report was a certain thing. Had these individuals been present Mr. Binko's application would no doubt have been acceded to. It is to be hoped that this gentleman, who of course was considerably disappointed at the unexpected turn of affairs, will accept the terms of the resolution passed at the council meeting, and construct the railway along the North Beach from the Britannia Pier to the North Battery. It might also be that the council, when they saw it at work, would withdraw their objection to an electric railway on the Drive, and that next summer the scheme may be carried out.

ELECTRIC LIGHTING AT WIMBLEDON.—At the annual meeting of the members of the Association of Municipal and Sanitary Engineers and Surveyors, a paper was read by Mr. Santo Crimp on the recent electric lighting trials at Wimbledon. The area of Wimbledon is 3,220 acres, and the population exceeds 20,000, the ratable value being £170,000. The number of street lights is 361. The street illuminant was originally gas, but the high rate charged by the company led the local authority to seek other means. Seventy-six incandescent lights were worked for eight weeks an average of six hours per night, at a cost of 0·378 of a penny per 25 candle-power light per hour. The cost for attendance would have been ample for 400 lights, which, if employed, would have reduced the expense to 0·2 of a penny per lamp per hour. The author of the paper, who is the surveyor of the district, reports this form of light to be devoid of all the defects of oil and gas,

Digitized by Google

the light is absolutely steady ; it can be turned on or off or regulated at pleasure from a single station, and is independent of the weather. All the street lamps at Wimbledon have been lighted for three years by oil, which is stated to be generally approved of by the inhabitants, and to be far cheaper than gas.

ELECTRICITY IN THE MENAGERIE.—An American contemporary says :—"Nearly every day some new use is found for electricity, and one of the most recent applications of this power is in the interest of the professional tamers of wild animals. The inventor is a tamer himself, and his instrument is an apparatus shaped like a stick and highly charged with electricity. When the animals become unruly he gives them shocks from this battery, and the effects are said to be instantaneous. On experiment three of his lions immediately showed signs of the greatest terror. They were seized with trembling and growled fitfully. The tiger was more quickly subdued, became stupefied, and crouched in a corner of the cage. Bruin was more refractory to the electricity, which seemed scarcely to affect him. He would growl and show his teeth, but was subdued after repeated discharges. The most astonishing effects, however, were perceptible in the boa constrictor. On receiving the discharge the specimen from Cayenne, nearly 20ft. in length, became at once paralysed, and remained motionless for six hours afterwards. When he recovered he showed signs of helplessness for three whole days. Finally the elephant, on being electrified by a touch of the stick upon the tip of his trunk, set up a series of wild cries, and became so frantic that the tamer feared he would break his heavy iron chain."

THE ELECTRIC LIGHT AT KIMBERLEY, SOUTH AFRICA.—On the occasion of a fancy dress ball, which during the past month was given in the Theatre Royal at Kimberley, the two ball rooms, the smoking room, and the middle room were lighted by electricity. Mr. Cousens, the electrician, spared no pains, says the *Kimberley Daily Independent*, to place his department beyond the reach of cavil, and though the shower of congratulations which he received must have been embarrassing they were nevertheless well deserved. Hanging from the roof were five large arc lamps, which by themselves shed radiance around. To this fine display was added 38 small incandescent lights, which were distributed in the form of arches over the various entrances, over the main arch, and at the back of the dais. These latter gave the place a kind of glorified Arabian nights' look, when Haroun-al-Raschid was lord at Bagdad. Many were astonished at the presence of the electric light, and its appearance was not obtained without a great deal of trouble on the part of Mr. Cousens. The spare machine was removed from the electric lighting head-quarters at the Municipal Compound and placed in Tarry's shop, about 300 yards behind the theatre. The whole was worked by one of Mr. Tarry's engines. One of the guests, who was got up as Aladdin, wore an incandescent light on his turban that flashed all over the place, and rendered him more than conspicuous. The idea, says our contemporary, to whom such things are novel, was certainly a clever adaptation of electricity.

ELECTRIC LIGHT ON S.S. "BARRUMBEET" AND "CORANGAMITE."—As showing the enterprise of the owners in adopting the latest improvements, these ships have been fitted up with the electric light throughout, in addition to and quite independent of the ordinary lamps. The installation is probably one of the most complete ever fitted in a steamer, the light being applied not only to all saloons, state rooms, passages, fore cabins, seamen's forecastles, pantries, galleys, store and lamp rooms, engine rooms, stoke-holes and shaft tunnels, but also to the side and masthead lights ; and a number of lamps, including hoisting lanterns, are arranged about the decks, which can be used either for lighting the decks as a promenade, or for lighting up the hatchways, decks, machinery, &c., when loading or discharging cargo at night. A horizontal double cylinder Tangye engine is placed in the engine room, driving an Andrews patent "Woodside" dynamo at 425 revolutions per minute, which provides current for the 160 lamps. This machine has been specially designed for ship use. It can be taken to pieces with little labour and in confined places. The current is divided into five main circuits by a switch-board placed close to the engine. The first circuit supplies light to the whole of the first-class accommodation, and is again divided into three circuits by a switch in the pantry, viz., one for the saloon, one for all sleeping apartments, and a night circuit supplying the lights in the passages, lavatories, &c. The second circuit supplies the officers' quarters, the third the second class cabin and seamen, also subdivided like the first, the fourth the engine rooms, and the fifth the decks and cargo lights. The light in the saloons has a most pleasing effect, and we have no doubt will be appreciated by the passengers. The installation has been carried out in a most efficient manner by Messrs. J. D. F. Andrews and Co., Woodside Electric Works, Glasgow, under the direction of Mr. M'Kay, superintendent for the owners. The pneumatic bells throughout the two ships have been fitted up by the same firm.

EARTHQUAKES.—The movement of the earth seems to be more or less general in its character. A violent shock has been felt at Doui, Dognies, and Flers en Escrebieux in France. The phenomenon was preceded by a rumbling sound, which is described as having resembled the distant report of a cannon. It occurred at ten minutes past 4 o'clock in the morning, when most of the inhabitants were still in bed. Many of them were awakened by the shock, and were so alarmed that they rushed in their night clothes out of their houses into the streets and roads. The oscillation of the ground stopped a great many of the clocks. No very serious damage was done. A distinct shock of earthquake of a few seconds' duration has also been experienced in Melbourne. The shipping in the bay was visibly agitated, and at the Observatory a number of instruments were disarranged and some of the lighter ones overturned. The shock was chiefly confined to the northern and southern suburbs, the eastern and western hardly experiencing the phenomenon. Telegrams from Gippsland stated that the shock had been severely felt throughout the province, and also at Wilson's Promontory. At Gabo Island the shock had also been felt. A telegram from Simla, which was dated June 29, announced that after an interval of three days, during which there was no seismic disturbance, shocks of earthquake occurred at Srinagar with renewed violence on June 24 and 25.—Scotland has also experienced several shocks. The Fort William correspondent of the Press Association telegraphs :—"Another shock of earthquake was felt in four different places in Loch Aber on Saturday. At Blarmaefoldoch, a crofter, while hoeing potatoes, heard a strange sound, and felt the ground trembling. He stood still while it passed away. At Lochulside a farmer coming with a horse and cart felt the vibration for about two minutes. At Banavie several persons felt the shock quite distinctly, and at Fort William two joiners at work felt the floor shaking, and some glass in the shop was rattled." The Carlisle correspondent of the Central News telegraphed on Wednesday night :—"A severe shock of earthquake was felt in the Lake District to-day. At Grasmere and at Ambleside

Digitized by Google

much alarm was caused, the shocks being accompanied by a noise like thunder."

THE TELEPHONE SYSTEM IN INVERNESS.—The rapid and easy means of intercommunication offered by the telephone, and the advantages of its exchange system, through which conversations can be carried on almost as easily by persons miles apart as between those sitting in the same room, has led to a very considerable extension of the National Telephone Company's system in Inverness. The central office in Union-street was opened in the beginning of the present year, with a membership of forty-two subscribers, with call offices at Union-street, Muirtown, the Thornbush, and at Kessock Ferry, for the use of the general public. Since the issue of the first list for the Inverness District in January last, the manager, Mr. J. Townsend, has secured no fewer than sixteen new subscribers, and opened a new call office at the Slaughter House for the benefit of the fleshers and others. The new list, which has just been issued to subscribers, shows that there are now 63 places of business connected with the Exchange, 58 of these being subscribers' premises, and five call offices. The wires of the company extend all over the town—from the Exchange in Union-street to Kessock Ferry on the one hand, and to Annfield on the other; and from the Distillery at Millburn to Muirtown Wharf. In order to enable the operator at the central office to "switch on" any two subscribers rapidly, all the members have a wire direct to the Exchange, so that the company in establishing communication between their members have had to put up wires extending over a circuit of 27 miles. No fewer than 71 telephones are in daily use in Inverness, and we are informed that the record kept of the calls by each subscriber shows that on an average each receives about eight messages by telephone per day. At the opening of the system in January last, the number of messages averaged about 300 per day. The number has in the interval almost doubled. Last week no fewer than 4,000 messages were transmitted, or an average of over 600 per day. This shows that the advantages of the system are in every way appreciated by the subscribers, and that the telephone is being largely used in the way of business. The call offices which have been established for the use of subscribers and the general public at Union-street, the Thornbush, Kessock Ferry, Muirtown, and the Slaughter House have been found of great service, and have been largely taken advantage of. Efforts are being made to still further extend the system in Inverness.

INCIDENTS OF THE BATTLE OF BANTRY BAY.—During the course of the engagement a small flotilla was detached to attack the "Hotspur," which, lying close in shore, was entrusted with the task of protecting the torpedo field, and right well she did it, sweeping her electric light swiftly all about, and bringing her guns to bear on every object that came within the brilliant beams. No sooner had the attack commenced than a continuous rifle fire was opened all along the line from boats moored by the boom, from marines lining an embankment on the shore of Bere Island, from bulwarks and rigging of gunboats and corvettes. Batteries hitherto masked belched forth an enfilading fire from both flanks on the boats as they came across the broad path of moonlight, or were exposed by the searching gleam of the electric lamps. For more than five minutes in one case a group of steam launches and rowing pinnaces was exposed to the hail of case shot without being able to escape from the fierce white light that followed them wherever they went. At this moment the scene was one of probably unexampled magnificence. On all sides the black hills around were lurid with what appeared to be a seething cauldron of fire and smoke; blue, green, and red lights flickered, or darted hither and thither, and the cold white beams of the shifting electric light shone through the turmoil, illuminating, now the boom with all its formidable defences, now a flying torpedo boat, and now a steam pinnace, rigged for jumping obstructions, and rushing head on into the line of spitting flame and cloud that betokened the position of the defending boat. The "Polyhemus" had to run the gauntlet of a formidable array of defences, and one would have thought her chances of getting through without being put over almost hopeless. Going a mile or two outside the harbour mouth, she gradually got up speed as she circled round and round like an eagle in flight ready to swoop on its prey. As her speed increased up to seventeen knots or more, the sea at her prow rose higher and higher, breaking in a white seething ridge from which flakes of foam slid down the green steep wave. Then, as she turned head to wind, the spray dashed high above her forecastle, and the sunlight fell in a shower of rainbow hues. Then pointing straight for the defensive works she seemed to skim over the water. As she passed across the field of submarine mines several electric contact batteries exploded, showing that they had been well laid and had sustained no injury during their long immersion in water that has been by no means undisturbed.

DECOMPOSITION OF CARBONIC ACID GAS BY THE ELECTRIC SPARK.—Various chemists have investigated the decomposition of carbonic acid by the electric spark. Experiments having shown that no explosion is propagated by a spark in a mixture of carbonic oxide and oxygen dried by standing over anhydrous phosphoric acid, it seemed of interest to repeat the experiments on the decomposition of carbonic acid when dried in a similar manner. Carbonic acid dried over anhydrous phosphoric acid was submitted to a series of induction sparks in a eudiometer by means of a chain composed of short pieces of platinum fused into small glass bulbs. The amount of decomposition varied from time to time, approaching no fixed limit. Similar results were found on introducing a Leyden jar into the secondary circuit of the Ruhmkorff, but the amount of decomposition was less. On passing a series of induction sparks through a dried mixture of carbonic oxide and oxygen partial combination gradually took place, but no fixed limit was reached. Two similar eudiometers were prepared and fitted with wires made of an alloy of platinum and iridium, each wire ending in a bulb about 2 mm. in diameter. The bulbs were brought to the same distance apart in the two tubes. On bringing an equal volume of dried carbonic acid into the two tubes, and sending a series of sparks from one Ruhmkorff coil through both tubes at the same time, the gases in the two vessels were found to be equally affected, their volumes varying exactly together so long as the pressure was kept the same in the two tubes. The more feeble the spark the greater was the decomposition of the carbonic acid found to be. When 100 volumes of dried carbonic acid were brought into one tube, and 150 volumes of a dried mixture of carbonic oxide and oxygen were brought into the other, and a series of sparks were passed through both from the same coil, the volume of carbonic acid increased, and the volume of carbonic oxide and oxygen diminished, until after some hours they became equal. On a further prolonged passage of the spark the two volumes altered together, sometimes increasing and sometimes diminishing, as the nature of the spark varied. A coil of fine platinum wire was heated by an electric current to whiteness in dried carbonic acid. No permanent alteration of volume was produced. When a similar coil of platinum wire was heated in a mixture of dried carbonic oxide and oxygen, it glowed intensely for some minutes, and complete combustion was found to have taken place between the two gases. No flame was visible round the wires.

Digitized by Google

COLLIERY EXPLOSIONS.—A very interesting correspondence upon the above subject appeared in a recent issue of *The Times*. Lord Thurlow, whose knowledge of electric lighting renders his remarks especially valuable, says :—"It is to be hoped that your remarks on the Clifton Hall Colliery explosion will open the eyes of the Home Office, the Board of Trade, colliery owners, and all concerned to the necessity of making electric lighting compulsory in all coal workings. No mechanical or scientific difficulties exist, and no special lamp has to be invented, as the ordinary 20 candle-power incandescent lamp is perfection for the purpose. A small first cost need only be incurred, and a direct and immediate saving would be effected, the cost of electric lighting being less than one-half that of oil, with ten times the efficiency, besides not vitiating the atmosphere, to which advantages add the future absence of periodical explosions in 'fiery' pits, which, you tell us, have cost this country 40,000 lives and over a million of men injured during the last 30 years, not taking into consideration the support of their widows and orphans. I will not ask for more space to-day, or I might urge the almost equal claims to electric lighting of flour, cotton, and other mills where the atmosphere is charged with combustible or highly inflammable dust." Another correspondent, Mr. Radcliffe Ward, also writes as follows :—"One point you bring strongly forward, viz., that it is to electricity that we must look for a light which, while perfectly safe, is also sufficiently brilliant to give the miner all the light he wants. As one connected with the electric light from its industrial birth, I feel the greatest interest in what I am certain might be made one of its greatest and most profitable uses from every point of view, and this I desire to state, viz., that during the last two years I have had occasion to examine both into secondary and primary batteries, the former which, if put into proper shape, could certainly furnish a satisfactory portable miner's lamp. As regards accumulators, there is no question whatever that portable (and for mining purposes the lamps must be portable and not worked off wires exclusively) miners' lamps can be made, and their working cost, charged from a motive power at the pits, costing an almost inappreciable amount, would be far less than the existing method of illumination. It is a process that appeals to one's common sense that, where power is so cheap and abundant as on a coalpit, a method of lighting whose chief consumed material is power should be the means *par excellence*. And there are literally no serious difficulties of detail to overcome which stand in the way of a portable electric lamp, charging and working plant being attached to every fiery mine in the country. Distinctly it is a subject those having the direct appliances to work with should lose no time about. Accumulator and lamp manufacturers are those from whom we have a right to expect the necessary apparatus. And as regards primary batteries I believe that even with these it is possible to get a satisfactory portable lamp, and there is at least one which promises to be sufficiently handy and portable for this purpose."

RESEARCHES ON THE DETERMINATION OF THE DIELECTRIC CONSTANT OF GASES. *Phil. Mag.*—Dr. Ignaz Klemencic, of the University of Graz, has determined the dielectric constant of some gases and vapours by the following method:—A large condenser, consisting of thirty nickel-plated brass circular plates of 25·76 cm. diameter, was put upon a plate and covered by a glass globe fitting air-tight to the plate. The plates of the condenser were separated from each other by small ebonite plates, 0·89 mm. thick; but the rest of the space could be filled with air or any other desired gas. The density of this dielectric medium could be varied within certain limits, and the pressure read off upon a manometer. The condenser was placed in communication with an air-pump and with large glass globes by means of tubes provided with taps. The condenser and glass globes could be exhausted to a tolerably low pressure, and it was also possible by means of a branch tube to fill the condenser with any gas at a high pressure. When it was necessary to exhaust the condenser rapidly, it was simply placed in communication with the exhausted glass globes. This condenser was charged 64 times in every second, and discharged as frequently through a sensitive galvanometer by the use of a tuning-fork, from a powerful battery of 22 small Bunsen elements with solution of potassium bichromate. The deflection of the galvanometer needle thus produced is, as is well known, a measure of the capacity of the condenser. If the electromotive force of the charging battery and the frequency with which it is charged and discharged remain the same, any change in the capacity of the condenser produces a corresponding change in the deflection of the galvanometer. If the dielectric constant of the medium varies with the density, then every change in the pressure within the condenser must produce a change in the position of the galvanometer needle. The deflection produced in the present case by the discharge of the condenser was much too large to render possible the observation of such a difference in position; it was therefore necessary to compensate this deflection, *i.e.*, by means of an equal opposite action upon the galvanometer needle. Of the various possible modes of compensation the author employed that of a constant current. A weaker battery (compensation battery of 4 Daniell cells) was employed to send a current through a large resistance, and through the coil of the galvanometer in the direction required to produce a deflection opposite to that given by the discharges of the condenser. By altering the large resistance of the compensating current, it was easy to arrange that the needle should remain in its position of equilibrium under the simultaneous action of the two currents. If this adjustment had been made for a definite capacity of the condenser, and if then only the density of the dielectric medium was varied, a deflection of the galvanometer needle was observed, due to the change in the capacity of the condenser produced by the change in density, and consequently in the dielectric constant of the medium. The ratio of the dielectric constants for two different densities of the medium may be calculated from the easily determined deflection produced by the compensating current and the observed deflection. In this calculation it is only necessary to take account of the circumstance that a small part of the condenser discharge passes through the compensation-circuit, and not through the galvanometer. As is well known, both Prof. Boltzmann and Messrs. Ayrton and Perry have employed the electrometer for their investigations on this subject. The condenser was charged for a much longer period than in the present case; and this constitutes an essential difference between the two methods. It is a great advantage of the galvanometric method that good insulation is by no means so necessary as with the electrometric method, and thus one of the chief difficulties which such measurements offer is avoided. The question whether the accuracy of the results is disturbed by electricity produced by the friction of the gas admitted to the condenser does not here arise. Besides the seven gases already examined by Prof. Boltzmann, the author has also examined the dielectric constant of five vapours. The results obtained with the seven gases and the vapour of carbon disulphide agree very well with the determination of Boltzman, and with the electro-magnetic theory of light. The dielectric constants of the remaining vapours do not satisfy the conditions given by this theory.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 79.)

Dielectric Displacement and Absorption.

The most remarkable and distinguishing feature of Maxwell's theory of electromagnetism is his dielectric current, whose introduction into the theory gives us a dynamically complete system, with propagation of disturbances in time through the medium surrounding and between conductors, doing away with the mathematically expressible, but practically unimaginable, instantaneous actions of currents upon one another at a distance, and similar, though more simply expressible, instantaneous forces between imaginary accumulations of the "electric fluid." Some might say that the distinguishing feature is his dielectric displacement. But it is scarcely that, strictly. For that a dielectric medium was put into a state of polarisation by electric force was Faraday's idea, and this polarisation is only another name for electric displacement. Again, Sir W. Thomson had given mathematical expression to the idea of polarisation in a dielectric; the statement $D = cE/4\pi$, expressing the displacement or polarisation in terms of the electric force, had been given in a somewhat similar form by him. Whether we call it displacement or polarisation does not matter; the important step made by Maxwell was the recognition that changes in the intensity of polarisation constitute a real electric current (though without dissipation of energy in Joule heating), and that the electric current, whether conductive or not, is always continuous. Accumulations are done away with altogether, and with their abolition the fluid or fluids become meaningless.

As regards the term displacement, though it may be objected to as misleading, suggesting a real displacement in a certain direction, whereas the phenomenon, though undoubtedly having some directional peculiarity, is probably not of the nature of a simple displacement, just as the conductive current is not the motion of a fluid through a wire, yet on the other hand, it is to be remarked that the term current is firmly fixed in use, and, to accompany it, there could be no better term than displacement. The time-integral of the current, from the zero configuration, in a dielectric, is the displacement; conversely, the current is the time-variation of the displacement. It would therefore be a pity to abolish the term displacement, unless we simultaneously abolish current; and it would be hard to find two words which fit together so well.

If we define the displacement as the time-integral of the current anywhere, not merely in a non-conducting dielectric, the current is the time-variation of the displacement anywhere. The displacement, reckoned from a proper zero at a certain time (any time when there was no dielectric displacement) is then, like Maxwell's true current, a vector magnitude of no convergence at every moment and everywhere. In some special investigations this is useful. We may then speak of conductive displacement and elastic displacement, but I believe in general it is best to confine the term displacement to elastic displacement (in a dielectric) only, unless we are careful to qualify the word by a preliminary adjective. In the absence of any qualification displacement in a dielectric is meant, and, should it be also conducting, the conductive displacement must be separately reckoned.

The difference between Maxwell's and older views regarding electricity and the electric current is instructively brought into prominence by making a small change in Maxwell's system, or rather in taking an imaginably possible, though really untrue, special case of the same. Put $c = 0$ everywhere. That is, stop all elastic displacement. Make no other change. The electric current is left continuous, and is now necessarily confined to conductors only, and at their surfaces must always be tangential. But there will still be magnetic force and induction, mutual forces between circuits, induction of one circuit on another, and there will still be transfer of energy through the medium from sources to sinks of energy. We have simply done away with the "elastic yielding of the connecting mechanism." The velocity of propagation of waves, as the specific capacity is imagined to be reduced to nothing, becomes infinitely great, instead of being only that of light. The theory of the induction of linear circuits becomes that given by Maxwell, wherein dielectric displacement is ignored. No effect is produced upon the distribution of steady current set up by steady impressed forces, but in the first transient states there are great changes. In a linear circuit, for example, the current is now absolutely constrained to keep in the conductor, so that there can be no surface charges or static retardation. Though there is no electrification, there is still electric potential. But we cannot charge a condenser. Therein lies the difference from reality. To be able to do this, without employing Maxwell's dielectric current, we are necessitated to suppose that the current is not continuous, but that it is the real motion of something that can accumulate in places. We are also obliged to change the relation between magnetic force and current, as it implies continuity of the current everywhere. Many other changes are also required to make a consistent system, for one change necessitates another, and we shall ultimately come to something extremely different from Maxwell's system.

In view of the extreme relative simplicity of Maxwell's views, and their completeness without any artificial contrivances to save appearances, and in their modernness, referring to modern views regarding action at a distance, one is almost constrained to believe that the dielectric current, the really essential part of Maxwell's theory, is not merely an invention but a reality, and that Maxwell's theory, or something very like it, is *the* theory of electricity, all others being makeshifts, and that it is the basis upon which all future additions will have to rest, if they are to have any claims to permanency.

Electric displacement is primarily a phenomenon of the ether. Ether is perfectly elastic. It must be so if there be no absorption of the energy of radiations during transmission through space. This conclusion is of course independent of Maxwell's view of light being itself an electro-magnetic disturbance. If the energy of displacement be potential energy, the displacement, whatever it really be, is of a perfectly elastic character, in the absence of ordinary matter.

But when electric displacement occurs in a solid dielectric, if there be, as there must be, mutual influence between the ether and matter, we may expect the elastic properties of the matter to be communicated, apparently, to the ether. Thus, no solid is perfectly elastic, and, consequently, electric displacement in a solid dielectric is not perfectly elastic, as it is assumed to be in the formula $D = cE/4\pi$, with c invariable at any place, the linear relation between the displacement and the electric force.

A solid, under the influence of externally-applied force, is strained. If the strain be under a certain magnitude it is assumed to be perfectly elastic, so that whilst the stress remains steady the strain does not change; and on the removal of all stress the strain entirely ceases. But, in reality, if a certain applied force deform an elastic solid, and the force be kept on, the deformation slowly increases, as if the elasticity slowly decreased. And on the removal of the applied force the original zero configuration is not immediately recovered. The residual deformation will then slowly subside. If, after the first approximate return to the original state, the body be, by constraint, prevented from changing shape, the solid, which at first did not react against the constraint, will gradually do so, so that on the removal of the constraint, a second return, in a lump, towards the original configuration, will take place.

Remembering that a dielectric under electric stress is in a state of strain, we may expect there to be a corresponding electrical phenomenon. The displacement produced by a given constant impressed force should be, at first, appreciably quite elastic, but should thereafter slowly increase. On the removal of the impressed force the original displacement should at once subside, leaving a small residual displacement which should subside very slowly, as it came on. Or, if the residual displacement be fixed, so that it cannot subside, it should appear to gradually come back into existence, as elastic displacement

Digitized by Google

referred to the original zero, so that on the removal of the constraint a second sudden subsidence should take place.

This is what happens in the phenomenon of electric absorption in a perfectly insulating dielectric. Whether it be really true or not that a part of the electric displacement becomes intrinsic by reason of some *quasi*-rigid connection with a similar phenomenon taking place in the strained solid, there is no doubt that there is a remarkable resemblance in the details of the two cases. That the presence of the matter causes the displacement to be increased from what it would be with the same electric force in ether is a separate matter, as this refers to elastic displacement. ($c>1$ in all dielectrics, if unity in vacuo).

An elastic spring is therefore the most correct analogue to a condenser when we wish to make up a mechanical illustration of the electro-elastic properties of a solid dielectric. We may, for instance, take a flat spring, clamp it firmly at one end, and apply pressure or pull to the free end in a direction perpendicular to its flat sides. Consider the applied force to represent the E.M.F. of a battery joined to a condenser, and the displacement of the free end of the spring to represent the electric displacement in the condenser. The displacement will be proportional to the force, in both cases, approximately, and if by any suitable means we magnify, mechanically or optically, the motions of the spring under varied circumstances, we shall see a corresponding set of phenomena to those occurring under similarly varied circumstances in the case of the electric displacement.

But an illustration, which, though less exact, is more easily followed by the mind's eye, when we cannot render visible the absorption properties of a spring, is that which occurred to me when first making acquaintance with Maxwell's mechanical illustration, the parallel vertical tubes, containing water. This being rather complex, I substituted the following :—Electric displacement in a condenser is represented by the actual displacement of a piston in a cylinder from its position of natural equilibrium in the middle thereof, when the cylinder is perfectly air-tight and contains an equal amount of air on each side. To give motion to the piston, rods may be attached to it, passing through holes in the closed ends of the cylinder. Call the ends of these rods, outside the cylinder, a and b, and the two corresponding air spaces in the cylinder A and B, a and A being to the left, b and B to the right. If pressure be applied to a or a pull to b, or both, the piston will be displaced from left to right, and small displacements will be proportional to the corresponding applied forces.

The displacement of the piston corresponds to the total electric displacement in a condenser ; the applied force to the E.M.F. of the battery on the condenser ; the back pressure of the rod a to the difference of potential of the condenser plates ; the displacement of a inward to the positive charge, and of b outward to the equal negative charge. Insulation of the condenser is represented by fixing a or b so that the displacement cannot change.

If we like to carry the illustration further, we may cause the rods a and b to meet with frictional resistance when moving proportional to the speed of their motion. This speed will correspond to the strength of current, and the coefficient of friction to the resistance of the conductor joining the poles of the condenser. We may go further, and suppose the mass of the piston and rods to represent the self-induction coefficient of the electric circuit, thus obtaining an illustration of the oscillatory discharge which occurs with suitable values of the resistance, capacity and self-induction. Although this analogy, which is well known in one form or another, is very close, and therefore educationally valuable, it should be remembered that it suggests that the momentum of an electric current is that of matter moving with the current, or of the current itself, if it be the motion of matter, having therefore necessarily momentum. So far it is apt to mislead ; for electricity has no momentum itself or kinetic energy. The momentum is that of the magnetic induction, or is proportional thereto, and it, and the (nominal) energy of the current, exist wherever there is magnetic induction, not merely in the wire.

To imitate absorption, make the piston very slightly leaky. Then if a be pushed in by a steady pressure, the first displacement of the piston is elastic with reference to the proper zero, the middle of the cylinder. But air then leaks slowly from B to A on account of the increased pressure in B, which causes the back pressure of a to decrease, and allows the same applied force to slowly increase the displacement. (This corresponds to the slow continuous increase of electric displacement in a condenser when a constant battery is kept on.) Or, if a be fixed, the back pressure will slowly fall whilst the displacement remains constant. (If the condenser be insulated, its difference of potential will fall whilst its charge remains constant.) Unfix a ; the first return equals the first displacement, approximately, but there is left a small displacement which will slowly subside if the piston-rods be free ; or if a be fixed a pressure at a will be gradually brought on by the slow leakage from A to B, so that a second sudden motion of the piston back to its proper zero can be got on unfixing a. (Remove the battery, but close the circuit still ; the first discharge will approximately equal the first charge, but there is left a small charge which will slowly subside if the circuit remain closed ; or, if it be insulated, a difference of potential of the same kind as before will gradually come on, so that a second discharge can be got on again closing the circuit.)

To instantly remove the displacement of the piston after leakage has occurred, we must apply an opposite force, a pressure at b or pull at a of the right amount to bring the piston to the middle. If we then fix a and leave the thing to itself the pressure of the rod at b will gradually subside. Similarly if we, after absorption has occurred in a condenser, and the first discharge has been taken, charge it oppositely by a reverse E.M.F. of the right amount to make the real displacement zero, and leave the condenser insulated, the apparent opposite charge will gradually disappear.

Since the first discharge equals the first charge we may regard the capacity of the condenser as being constant, and the displacement at any moment to consist of two parts, first that due to the battery E.M.F., which can be got rid of at any moment, and next a temporary intrinsic displacement which is kept up by impressed electric force in the dielectric itself arising from its altered structure, or the changed zero of its elastic deformation. The displacement due to a certain total E.M.F. in the circuit is the same however it be distributed, whether in the conductor or dielectric, if, over any cross section, it be evenly distributed. But only the part in the conductor causes difference of potential in a steady state between the ends of the conductor, so that the intrinsic displacement due to internal impressed force gives no external sign of its existence until, by the removal of the impressed force, difference of potential is developed between the terminals of the condenser.

In the case of the piston in the cylinder, the intrinsic force keeping up displacement of the piston after the rods have been set free is the pressure of air in A against the piston from left to right which, had it not been for the leakage, would have been in B, and have pressed the piston the other way.

Another effect may be mentioned. If the dielectric of the condenser be of such a nature that its capacity increases or decreases with the temperature, then, on suddenly charging it, there will be a cooling or a heating effect produced in the dielectric. This has also its parallels in the metal spring and "spring of the air" illustrations.

Intrinsic displacement in a dielectric, without conducting matter surrounding it, to render the displacement wholly latent, has also some interesting features, which will be next considered.

(To be continued.)

The Eastern and South African Telegraph Company notify that the coupons due on the 1st inst. on their Five per Cent Mortgage Debentures, will be paid on and after that date at the banking house of Messrs. Barclay, Bevan & Co., Lombard-st.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Within the last eighteen months a very considerable amount of work, on a more or less extended experimental scale, has been devoted to the solution of the questions in relation to secondary batteries, which have forced themselves on the attention of practical electricians. This work has been attended with fairly commensurate results; and, indeed, great progress has been made, although this cannot be said to have been yet realised in practice. Readers of the current scientific literature during the above-mentioned period can scarcely have gathered therefrom any intimation of this progress; and until quite recently, when my friend and old pupil, Mr. F. G. Howard, read his paper to the students of the Institution of Civil Engineers, there was a noticeable dearth of all communications in relation to secondary batteries. Some of the causes of this dearth are still existent. Many workers are too busy with experimental verifications and practical developments to be able to devote time to the writing of papers; and for prudential reasons they are bound, moreover, to keep to themselves, for the present, the results of recent investigations. Mr. Howard deserves the credit of having directed renewed attention to an important subject; but his paper, retrospective and dealing with what is already semi-obsolete, or likely to become so, requires to be supplemented by one more prospective in character, and placing the student more *au courant* with the present aspect of the main questions involved—such a paper, for instance, as might be written by another young friend and old pupil of mine, Mr. W. H. Tasker. For the reasons to which I have adverted it may be some time, however, before such a paper can be forthcoming.

At the present time it may be useful, in the first place, to refer critically and briefly to a few points involved in Mr. Howard's paper.

(*a*) It is not an accurate description of the electro-chemical and chemical effects produced in "running down" a lead secondary battery in an electrolyte of dilute sulphuric acid to say that "The result is the reduction of the peroxide of lead on the one plate to oxide, and then to sulphate of lead from the presence of the sulphuric acid in the solution; and of the spongy lead to sulphate of lead." The most casual examination of the "spent" negative element of such a battery is sufficient to show that the active material has certainly not been converted into a white substance such as sulphate of lead—a very bad conductor of electricity, and affected by electrolysis only with difficulty. And the fact that no oxide (monoxide) of lead can be produced by the effect of the oxidation of the lead positive element is confirmed both by theory and by observation. The spent negative material always contains, it is true, some sulphate of lead; but it is essentially a compound analogous to minium or red lead, and, like this body, variable in composition* according to circumstances. In a properly worked battery, but little sulphate of lead should be produced in the cathode of discharge. Although (*meâ culpâ*) I have never had the industry to carry out a series of analyses of spent negatives, and have hitherto failed to induce any of those who are commercially interested in secondary batteries to have such analyses made by chemists with time at their command—in other words, although I am almost as ignorant on the matter as any of my *confrères*—I have, from certain observations, come to the conclusion that the spent negative material in a carefully worked battery should approximate to the composition represented by Pb_2O_3. In regard to the positive element in a lead secondary battery, I cannot go with Mr. Howard further than to admit that the active material (spongy lead) is *partly* converted into sulphate of lead. An experiment with a couple of E.P.S. grids from which the spent material is removed and replaced by sulphate of lead would no doubt modify the notions held by some electricians in relation to the chemistry of the secondary battery.

(*b*) Referring to Mr. Howard's table of storage capacity, the work per lb. average of lead that could be stored in a theoretically perfect lead secondary battery (consisting wholly of active material) cannot be estimated as higher than 207,000 foot-pounds. The higher value of 360,000 foot-pounds is evidently based upon the assumption that one equivalent of lead peroxide would, at least theoretically, suffice for the oxidation by electrolysis of one pound of metallic lead, the potential difference being two volts during the whole period of the reduction of $Pb\,O_2$ to $Pb\,O$. But it is very certain that no such assumption can be allowed. We cannot accept the equation

$$Pb + Pb\,O_2 + 2\,H_2S\,O_4 = 2\,Pb\,S\,O_4 + 2\,H_2O$$

as representing what took place during the discharge. We are forced to admit that, even theoretically, *two* equivalents of lead peroxide are requisite for the electrolytic oxidation of one pound of spongy lead under the potential difference of about two volts. The electro-chemical equation for the lead secondary battery would thus be

$$Pb + 2\,Pb\,O_2 + H_2S\,O_4 = Pb\,S\,O_4 + Pb_2O_3 + H_2O;$$

and three equivalents of lead would be involved in the electrolytic oxidation of one equivalent of this metal.*

(*c*) Mr. Howard is somewhat in error as to the specific gravity of dilute sulphuric acid, constituted of one part of sulphuric acid to nine parts of water; and it may be of importance that this error should be speedily corrected. In no case can the specific gravity of such a mixture be as high as 1·2. If the given proportion be taken by weight, the specific gravity will be about 1·068; if it be taken by volume, the specific gravity will be not higher than 1·13. Roughly, the addition of two parts of sulphuric acid by volume to nine of water gives the specific gravity 1·2.

Mr. Howard in his paper apparently refers to a certain battery, in which the cathode in charging is composed of minium and carbon fragments, as the Crompton-FitzGerald secondary battery. But the letters patent in accordance with which this battery was constructed must be No. 4,178 in the year 1882, granted to FitzGerald and Jones. The letters patent No. 5,159, 1881, granted to Crompton and FitzGerald, do not refer to the use of carbon. The method and processes claimed in the latter have never been adequately tested experimentally.

By the way, electricians do not seem to be generally aware that spongy lead may now be obtained by the Keith process at a fraction over the price of sheet lead.

There is much to be said on the subject of the essential defects of secondary batteries as at present constructed—defects which, whatever Mr. Sellon may think or say, can never be remedied by "care in manufacture and ordinary attention to rules for working." There is, or will be, also, much to be said in regard to the various means whereby these defects may be obviated. I intended to refer in this letter to some very striking results which have been obtained by the use of a certain electrolyte in charging cells of the Planté type; but the present communication has already extended to a sufficient length, and perhaps what I have further to say may not lose in interest by keeping.—Yours, &c.,

DESMOND G. FITZGERALD.

* Three definite compounds, empirically represented by the formulæ Pb_2O_3, Pb_3O_4 and Pb_4O_5, and mixtures of them, are all included under the term minium. The first of the above is a compound of remarkable stability; reagents, such as mercurous nitrate and sulphurous acid, which instantly reduce the peroxide, having no action upon it; whilst on the other hand no plumbic oxide can be separated from it by the solution of potassic hydrate or of the normal plumbic acetate. The second of the above formulæ expresses the most usual composition of red lead

---

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must thank Mr. Sellon for the courteous way in which he has criticised my paper on the above subject, and will endeavour to reply in the same spirit.

Unfortunately it is evidently becoming the fashion, when a discussion is started on the merits of any particular apparatus used in the various branches of electrical engineering, that the manufacturers interested in that apparatus rush into print, and consider it their duty to herald forth to the world, in the

* Mr. Reckenzaun in his letter (p. 119) gives 360,000 foot-pounds as the energy evolved by the oxidation of 1lb. of lead. But this weight of the metal necessarily corresponds to 420,800 coulombs, or 117 ampere hours; and this quantity of electricity, under the potential difference of two volts, must of course be equivalent to 234 watt hours = ·3136 horse-power hours, or 620,928 foot-pounds.

Digitized by Google

most extravagant fashion, the perfection of their manufactures, and, not content with this, must needs condemn other manufacturers' goods as useless and utter failures; and also anyone disagreeing with them is immediately stamped as being either ill-informed or inexperienced. Surely this method of advertising their goods cannot be to their interest, as it is liable to make purchasers think twice as to which is really the best article, and whether they are justified in using any of them.

But to return to Mr. Sellon's remarks. I had no intention whatever, as he rightly surmises, of conveying the idea that secondary batteries are almost hopeless; they are far from that, and are every day being more and more improved. Again, that it is only within the last twelve months that any real advancement has taken place in improving the durability of the E.P.S. cells, Mr. Sellon will, I think, admit; and as I wrote my paper more than twelve months ago, I do not think my estimate of their life too low. Undoubtedly, it is quite true, as Mr. Sellon says, that this short life was simply in consequence of carelessness and bad workmanship in the manufacture; but I venture to think that no one is desirous of hearing how long batteries *might* last if properly made, but would preferably know what they are capable of doing as manufactured for commercial purposes.

I am very pleased to hear that Mr. Sellon has some of his original cells still working, and can only wonder why the Electrical Power Storage Company went so astray after taking up the manufacture, as surely they have thus thrown away golden opportunities, both as regards reputation and financial considerations. Mr. Sellon does not apparently consider that "skilled" labour for secondary batteries is necessary; yet he says they require *competent supervision*. How is this to be obtained, say, in a country residence where the owner is not an electrician? Surely an under gardener or labourer could not learn how to keep an installation going without somebody to supervise. I think that the term "skilled" labour has been somewhat misinterpreted; what I intended to convey by the expression was the employment of trained mechanics as opposed to under gardeners or labourers. Of course, where the owner of an installation is master of the subject a boy is often sufficient to keep the plant in working order.

In conclusion, I would add that I do not think that even Mr. Sellon is more convinced than I of the absolute necessity and importance of secondary batteries; and I can only hope that his efforts in this direction may ere long be crowned with that success to which they are so justly entitled.—Yours, &c.,

F. Geere Howard.

Cleveland Works, W., June 30, 1885.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS AT SWINDON.

On Tuesday last, the 30th ult., by the invitation of Mr. C. E. Spagnoletti, M.I.C.E., the president of the Society of Telegraph-Engineers and Electricians, a large party of gentlemen proceeded by special train from the Paddington Station to Swindon, where the works of the Great Western Railway Company are situated. There were about 450 present, amongst whom were Mr. E. Graves and Prof. Hughes, F.R.S., vice-presidents; Mr. W. H. Preece, F.R.S. (past president), Mr. Willoughby Smith (past president), Mr. R. E. Crompton, Prof. George Forbes, F.R.S.E., Mr. W. Crookes, F.R.S., Mr. A. Siemens, Mr. A. Stroh (members of council); Mr. Yoshida (Japanese Commissioner to the International Inventions Exhibition), Colonel the Hon. Le Poer Trench, R.E., Colonel Stotherd, R.E., Colonel R. Murray, Admiral Mayne, C.B., Captain Hall, R.N., Captain Sankey, R.E., Captain M'Evoy, Captain Holden, R.A., Dr. W. H. Stone, Dr. Steet (of the G.P.O.), Prof. H. M'Leod, Mr. G. L. Bristow, Dr. Fleming, Sir Henry Mance, Mr. W. T. Glover, Mr. H. R. Kemp, members; Mr. E. Dunkin, F.R.S. (President R.A.S.), Mr. R. Price-Williams, Mr. A. K. Mackinnon, Sir R. Rawlinson, C.B., Sir George Birdwood, M.D., Prof. G. G. Stokes, F.R.S., Prof. Frankland, F.R.S., Dr. Mann, M.D., Dr. Armstrong, F.R.S., Mr. Phillip Magnus, Mr. E. Woods (Vice-President Institution Civil Engineers), visitors.

On arriving at Swindon the party proceeded to the Drill Hall, where arrangements having been made for their reception, they were entertained at luncheon by Mr. Spagnoletti and several prominent officials of the railway company. After the usual loyal toasts, the President proposed that a vote of thanks be accorded to the Great Western Railway Company for the kindness with which they had placed their extensive premises, in a manner of speaking, at the disposal of the members of the society. This having been unanimously carried and briefly responded to by a gentleman connected with the railway company, the health of the President and veteran electrician of the line was proposed and drunk with a degree of enthusiasm that must, had he not been used to it, have embarrassed the worthy recipient. At the conclusion of the repast, they, under the courteous guidance of the president, had the pleasure of being conducted over the fine engineering works, which, covering 30 acres of ground, are among the largest in England; employing when fully occupied over 7,000 operatives. At periods of pressure they have turned out an engine a week, a carriage a day, and a truck per hour. The shops are nearly all stone built, and are most pleasantly situated in a verdant country, luxuriant with trees. The foundries, rolling mills, steam hammer shed, locomotive and carriage departments, and all the fitting shops were visited, the visitors being exceedingly pleased with the various machine tools employed, and the order and regularity with which these great works are conducted. Special attractions were the carriages used by Her Majesty the Queen and other members of the Royal family, which, elaborately decorated and fitted up, are models of perfection, both in design and construction. A somewhat amusing evidence of the loyalty of electricians was here given, nearly everyone of the party being anxious, even to eagerness, to repose, if but for an instant, upon the couch provided for our Sovereign. A very interesting relic of the earliest days of fast railway travelling, the once celebrated engine of George Stephenson, the "North Star," built in the year 1837, is still to be seen in the loco shed. It looked, and we were informed is still, as good as ever. At about 5:30 p.m. an adjournment was made to the hall, where refreshments of various kinds were provided, and at 6:50 p.m. the party returned to Paddington, where they, with good reason, thanked their genial host for the pleasure he had accorded them.

The Medical Electric Lamp.—The electric lamp used for examining General Grant's throat, says the *Scientific American*, is manufactured by agents of the Edison Light Company. It is mounted on a hard rubber holder, about 7in. long, having a reflector at the lamp end, by which the light can be thrown to any desired angle. The holder is connected by two silk-covered wires to a small storage battery carried in the pocket of the physician. The light is turned on by simply pressing a small button on the rubber holder, and the quantity is governed by another button convenient to the operator. The lamp is inserted in the mouth almost to the palate, with the reflector above the lamp, which throws the light down the throat. The lamp has no unpleasant heat, and gives a light equal to half a sperm candle. The extreme simplicity of the whole appliance makes it very valuable to the physician and dentist.

Electricity as a Reviving Agent.—A case illustrating the power of electricity to stimulate the action of the heart is reported from St. Albans, Vt. A three year old child was by mistake given a dose of morphine, and was so affected by it as to be apparently beyond help. A doctor was called, but to all appearance the child was dead, except that there was an almost imperceptible beat of the heart. An application of electricity was made and continued for four hours, at the end of which time resuscitation was completed and the child lives. During the process of restoration, if the poles of the battery were withdrawn the activity of the heart would subside, and it is very evident that but for the use of electricity death would have ensued.

ELECTRICAL PROSPECTS AND THE CRISIS.

Of the many things that have been unsettled by recent political events electrical interests may not be classed among the foremost; but they are of sufficient importance to call for a word of passing comment, if not of prophecy, at this juncture. We should be counted among the idiots were we to speculate on the possibility of the present "*ad interim*," "stop-gap," "caretaking," "makeshift" Government being in power next year. A Ministry thus lugubriously christened almost before it is born, is, we are publicly assured, doomed to die in infancy. Its sponsors being, as everybody knows, half-inspired and wholly prophetic, nobody dare question their predictions. But we may venture to whisper in an undertone that if this child of sin were to live and prosper for any reasonable length of time, the result might not be altogether unsatisfactory to our clients. We have, for example, hardly anything to hope for from a resuscitation of that supremely virtuous but inconvenient political child who always persisted in having his cake and eating it. The interests involved in the Electric Lighting Act were a cake of this kind. It was a proud achievement of the presiding genius at the Board of Trade; but it was to be eaten all the same as soon as the morsel was done to his liking. The rights of local authorities and the dangers of monopolies were the actuating motives—motives of the purest, no doubt; but with a graceless Minister at the head of that department we might confidently look for a fair share of the cake—the share which erring mortals are entitled to. In other words, it is highly improbable that a Conservative President of the Board of Trade would do other than disapprove of a measure for confiscating the fruits of private enterprise in order to enrich public Bumbledom. Moreover, it is well known that the new Prime Minister is a warm patron of the electric light; and we have it on recent record that he cited Mr. Chamberlain's famous Act as a sample of how the ransoming theory put into practice had stifled and well nigh ruined an industry of great wealth and promise. If the electric light were to burn bluer than ever at the next General Election, Mr. Chamberlain at all events ought not to wonder at it.

It is probable that the Bill giving effect to the international agreement with regard to Submarine Cables will contrive to get passed sometime before the close of the present session. The same cannot be confidently said of the Telegraphs Act Amendment Bill authorising the experiment of a sixpenny rate for telegrams. Signs are not wanting that the governmental caretakers will have enough to do to take care of themselves. They are to be "supported in doing right," and "it is not anticipated that they will do wrong," which can mean no other than that they will be forbidden, even if they attempt, to do anything besides or beyond what their condescending critics do not oppose. It happens that this particular Bill was opposed not only by members who are in opposition, but by at least one member who is now in office, and into whose hands the Bill has actually fallen. Lord John Manners threatened it on the free address question; and he can hardly at once proceed with a measure which settles that question in a way that he disapproves of. On the other hand, he may have equal difficulty in upsetting the arrangements of the permament officials who are to administer the Act, and who presumably approve of its provisions. The retiring Postmaster-General has publicly stated that if the telegraph is to be self-supporting the reform ought to be carried out in the manner devised by him. There is no reason to suppose that his successor regards the telegraph service as a non-paying concern, created for the purpose of subsidising its customers; and we may therefore hope that he will see fit, when in possession of all the facts, to let the Bill pass substantially as introduced. But a decent period will have to elapse before such a conversion can take effect, and, all things considered, the probabilities at present seem to point to the Bill being held over till next year. Its postponement will be the lesser of two evils, for it would be nothing short of a public misfortune if the opportunity were once again lost of placing the telegraph-tariff of this country on a basis which experience elsewhere and commercial principles everywhere point to being the right one. The charge and the scale of words are matters which may be determined by the financial position of the telegraphs for the time being; but the free addresses are a perennial abuse, and must be got rid of—if not this year, next.

Meanwhile, the telephone is making its impression on the revenue of the State telegraphs, and rendering greater the cost of concessions to the public without some compensatory set-off. It is sometimes hinted that the Telephone Companies want to be bought up; the circumstance just referred to certainly points to that arrangement as a conclusion to the present chronic state of rivalry; and the refusal of the late Postmaster-General to accede to the outrageous pretensions of the companies in regard to overhead

Digitized by Google

wires will tend in the same direction. Lord John Manners probably will view the encroachments of the telephone with no less disfavour than his immediate predecessor. Conservative Governments, after their expensive purchase of the Telegraphs and their disastrous negotiations with the Water Companies, may be shy of essaying another transaction of the same kind; but if a bargain is to be come to between Telegraph and Telephone it will be a Conservative rather than a Liberal Government that will carry it through. But this is beyond the power of any *ad interim* Government, and we must wait at least till the autumn before anything decisive on this, as on other points, can be foreshadowed.

OHM'S LAW AND POTENTIAL DIFFERENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The position as regards the heat formula $H = \frac{E^2}{R}$, discussed between Mr. Wilkinson and myself, under the heading of "Blind Mathematics," now requires to be re-stated. I am much obliged to your correspondent for the trouble he has taken in explaining to me how the formula in question is a correct deduction, according to the interpretation of it he has been good enough to give, and how it is practically useful, at least as a rule of thumb; meanwhile, he has probably been sensible of the objections which I continued to urge even after his interpretation. More on these points would scarcely be of public interest.

But Mr. Wilkinson will doubtless have perceived by this time that the original ground on which I charged electricians with mathematical blundering was my different notion as to what really is Ohm's law. And as Mr. Wilkinson has thought well, in his own words, "to lead me back to Ohm's law," I must ask him to tarry there with me awhile, in order to investigate what law has the true and prescriptive right to be called by such a title. And I propose to argue the matter, in the spirit of Socrates, as one who wishes to be corrected if he is in error.

To say that Ohm's law is $C = \frac{E}{R}$ would not be a sufficient answer, until the proper sense of the symbols is defined; and here lies the field of debate. Men of all times would agree that the above formula expresses Ohm's law, but there might be some difference on the question what was signified by E and R respectively. I am surprised to find how many electricians intend by these symbols "the difference of potential (E) between the ends of a resistance (R) carrying a current C."

On referring to Ohm's paper itself, I find that there really is a law framed by him referring to local volts and local resistance, and which, though more complex in its original form, might be rendered from a modern point of view by the symbols $C = \frac{v}{r}$, the small letters being used to denote local conditions.

But the climax of the working is as follows:—

"The second of the preceding equations becomes by the adopted change—

$$S = \frac{A}{L}$$

which is universally valid, and the equality of the greatness of the current at all parts of the circuit is at once evident from its form; it is expressed in words thus:—

"*The greatness of the current in a galvanic circuit is directly proportional to the sum of all the pressures* (spannungen), *and inversely proportional to the entire reduced length of the circuit.*"

The phrase "reduced length" refers to a diagram, and means something like "length in ohms," *i.e.*, resistance. (*Die Galv. Kette.* Dr. G. S. Ohm, p. 36.)

Now, I cannot help feeling that this $S = \frac{A}{L}$ is the formula which $C = \frac{E}{R}$ was originally framed to represent; and is not such a view confirmed by the traditional notion that "Ohm's law" (whatever it be) expresses the relation between three elements, viz., E.M.F., Resistance, and Current? But if, as I presume, E.M.F. is that force or sum of forces which moves the electric current, this element is found only in $C = \frac{E}{R}$ with the meaning of $S = \frac{A}{L}$.

It is only a confused mind that can tell me I am making a distinction without a difference, and that E.M.F. and potential difference are the same thing. To such I reply that as long as we are speaking of a circuit which is "carrying a current C," the E.M.F. is *one* for the whole circuit, just as much as the current strength, whilst potential difference may be detected in infinite variety according as it is reckoned between the terminals or over shorter distances, and meanwhile not one of them all indicates the E.M.F. of that circuit. The only case in which volts indicate E.M.F. is that of a possible circuit yet to be made, and accordingly this indication is given (1) at the insulated terminals of a rheomotor, and (2) at the two derivation points of any intended shunt.

The law of local volts (as I should prefer to term it) which shows the relation of current strength to *external* E.M.F. and *local* resistance, though of great practical utility, does not formulate a fundamental physical relation like the one whose symbols it has usurped, much less are the two laws identical.—Yours, &c.,

E. ALDRED WILLIAMS.

55, Cornwall-road, W., June 30, 1885.

THE TREATMENT OF REFRACTORY GOLD ORES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was pleased to notice in your issue of the 26th inst., a description of my process for the treatment of refractory gold ores by electrolysis.

Although in the main the description is an accurate one, it might be somewhat misleading from a chemical point of view, as a most important feature of the invention, and its bearing upon the process has not been indicated.

You state that by a secondary reaction a soluble iron compound is formed, which precipitates the gold, and thus prevents its extraction. But by not stating by what means I overcome this reaction, the impression would be conveyed that the gold remains behind in the revolving drum. Were this the case, my process would be of no value whatever. It is just because I can separate the gold from the ore and deposit it outside of the drum at the negative pole in a metallic state that I am enabled to treat successfully, and on a large and practical scale, all those refractory gold ores which have hitherto presented so many difficulties.

In order to prevent the salts of iron and other metals from precipitating the gold, I add the lime at a certain stage of the process. This lime immediately precipitates all the metals in solution with the exception of the gold, which, remaining dissolved, is deposited at the cathode in form of a black slime. The asbestos cloth prevents the gangue, &c., from reaching this pole, and the gold hence remains in a pure state.

The reactions which take place are briefly as follow: Nascent chlorine and nascent oxygen are generated by electrolytic decomposition of an aqueous solution of chloride of sodium, whereby the auriferous pyrites are decomposed. The gold becoming free is converted into auric chloride and is precipitated by the salts of iron, antimony, &c. Addition of lime, consequent precipitation of all metals except gold, which, as long as the solution is kept alkaline, is deposited at the cathode, until the last traces of it are extracted. I have thought it right to give this explanation as the matter has attracted considerable attention, and an erroneous impression might prejudice me.—Yours, &c.,

HENRY R. CASSEL.

London, E.C., June 30, 1885.

THE ELECTRIC LIGHT AT THE BUCHAREST NATIONAL THEATRE.

(Executed by the Société Electrique Edison, 8, Rue Caumatin, Paris, under the supervision of Francis Jéhl, Electrician to the Société).

Historical Notice.

Bucharest, the capital of Roumania, is a city of about 250,000 inhabitants. It is a cosmopolitan city, with large avenues and streets, luxuries that cannot be obtained better elsewhere. In fact, the area occupied per unit of population is perhaps greater here than in any other European city of like pretensions, the houses being mostly detached. The improvement of the town is principally due to the untiring energy of His Majesty Charles I., King of Roumania, who has built schools, opened academies, and is a great encourager of all that pertains to progress.

Among the finest of the buildings in Bucharest is the Theatre National, situated in "Calca Victoria," the principal street of the city. Some idea of it is obtained from the accompanying illustration.

Fig. 1.—The National Theatre, Bucharest.

The theatre was built about 37 years ago, and has space for about 1,130 people. The theatre is owned by the Municipal Council of the city. It was originally lighted by oil, and then by gas, the latter introduced in 1877. The auditorium consists of a parquet, three floors or rows of boxes, and a gallery. The lighting by gas consisted in the auditorium of a large chandelier, having 282 gas jets. On the first floor, projecting from each box, were 26 chandeliers, each chandelier carrying eight jets, making a total of 208. On the second floor were 20 chandeliers, with eight jets in each, making a total of 160, and on the third floor 22, each having five jets, making 110 in all. The total number of gas jets in the auditorium was, therefore, 760, not including the orchestra. Each jet of gas gave about five candles, equal to a total of 3,800 candles. The ordinary illumination consisted of about 350 jets. The heat caused, however, forced the managers of the theatre to close their season at the end of April. This, of course, prevented many people from amusement, but for the time nothing could be done to ameliorate this obstacle. When, however, electricity was applied to illumination, the matter was discussed by a committee, and they concluded to wait awhile, and inform themselves if this new light was really practical and adaptable. After watching through a period of nearly three years the work at Brünn, where is the first theatre which in Austria was electrically lighted by the Société Electrique Edison, and which has ever since given great satisfaction, it was resolved to light similarly this theatre at Bucharest. Experience has shown that this new light is adaptable to theatrical purposes, and that it has qualities superior to gas, especially when employed in theatres, halls, or any place where there is a gathering of people. It is steady, admits of easy regulation, does not increase the temperature so much as gas, nor emit any sulphurous fumes. It may be made perfectly safe against fire, which is an important consideration with managers of theatres. The Austrian public have not yet forgotten the destructive work one little jet of gas did at the Ring Theatre at Vienna a few years ago. That dark heap of bones buried in the Central Friedhof has done a great deal for the advancement of electric lighting.

The electric lighting of the Bucharest National Theatre is mainly due to the exertions of the Compagnie du Gaz de Bucharest, of which M. Masson, of Paris, is the president, while G. Darlu de Roissy is director and manager of the Company in Bucharest. This company, after receiving several proposals from different electric light companies, adopted the Edison system for its completeness, and at the same time made a contract with the Société Electrique Edison de Paris for a term of five years, in which both companies would jointly contract all business in Roumania. M. Steréadi, of the Theatre National, has also been very active in pushing the matter forward.

Machine Room.

The machine room was originally intended to be placed in a large and long cellar in front of the theatre. All plans were accordingly made for this purpose. The Municipal Council of the City, however, made an objection, and it was agreed to build a small house adjoining the theatre. The machine room is built just behind a large wall, forming a terrace, this being on a level with "Calca Victoria," thus shielding its view from the principal thoroughfare. It covers an area of 171·6 square metres, which is divided as follows :—

Machine room	66·4
Boiler room, reservoir, well, &c.	71·9
Magazine	14·6
Office	18·7
Total in square metres	171·6

Digitized by Google

Fig. 2 shows the front view of the machine room, together with the base of the chimney.

In the machine room, which is divided into two sections, are two high speed engines. The first section holds an Armington and Sims engine, driving two Edison machines, each capable of giving 400 16-candle lamps. The dynamo machines are of the new model, and connected in multiple arc, having their field regulated by one of the regulators. Fig. 3 is a sectional view of the whole house. Section 2 has also two dynamos of the same model, driven by a Porter-Allen engine. The connections are made in the same manner as those of Section 1, the current from all the machines entering the conductor on a switch-board placed just above the two regulators that regulate the field of both sections. This switch board consists of four large plug switches, which also make connection with lead plates or safety catches. Each pole of both sections 1 and 2 has a lead plate, and from this switch-board any one of the two sections can be cut out or put into circuit as desired. Besides this, each single machine can be cut out or put into circuit by means of switches accompanying each machine. Thus each machine, each section, or all together, are under perfect control. The field magnets of each section are connected in multiple arc, each machine having also a switch for its field circuit. In fact everything is done to insure a good working installation. Arranged upon the switch-board are two volt-meters and two ampere-meters, by which the electromotive force and current can be constantly tested. The volt-meters are connected between the poles of each section, and in order to see the current, it is only necessary to pull out the plug of that particular switch at the extremities of which the wires of the ampere-meters are connected. The current, being too strong to go direct through the instruments, is shunted through coils, the resistance of which is exactly known. Fig. 4 shows the

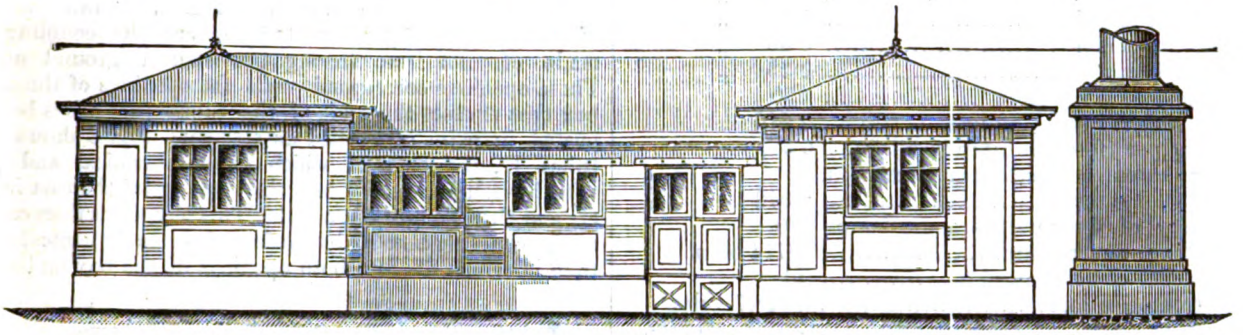

Fig. 2.—Machine Room.

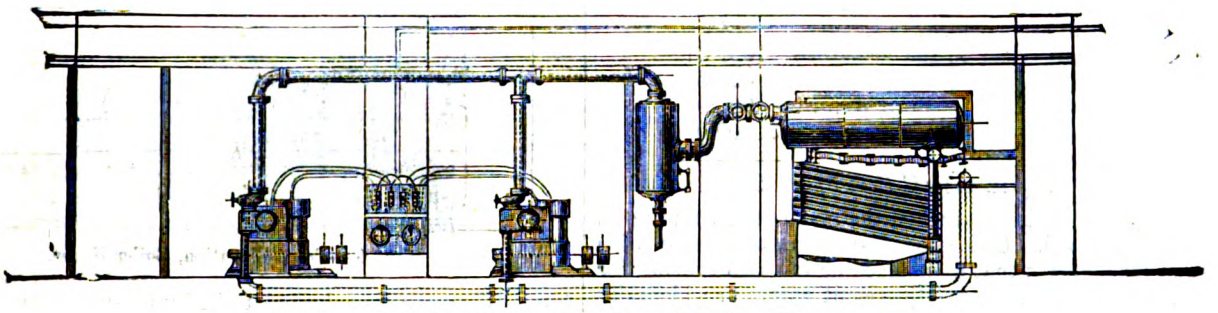

Fig. 3.—Sectional Elevation of Machine Room.

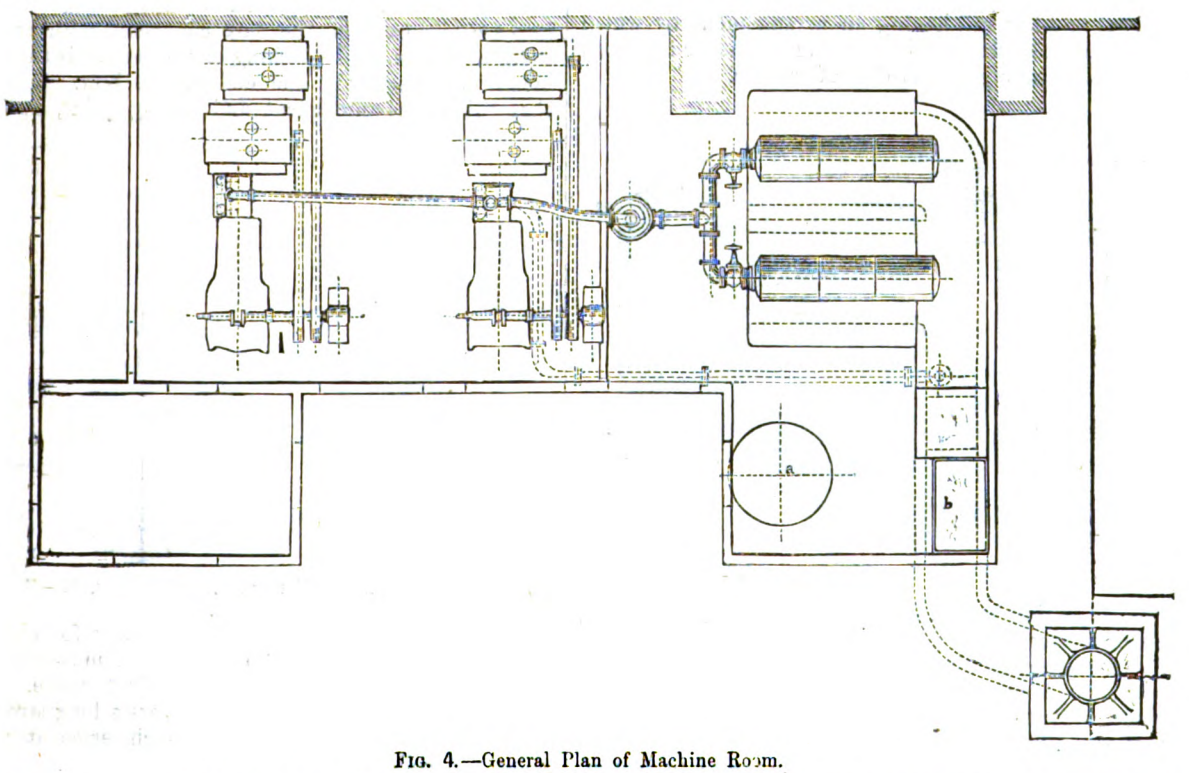

Fig. 4.—General Plan of Machine Room.

Digitized by Google

general disposition of the engine, dynamo machines, boilers, &c. It will be seen from this plan that the installation is very compact, regarding the number of lights that can be supplied from it. The new model of the Edison dynamo machine is claimed to be one of the most perfect, simple, and cheapest machines per lamp in the market to-day. The following are the dimensions and qualities of the machines installed at Bucharest:—

Base, length	1·75 metre.
„ breadth	0·96 „
Height of machine	1·41 „
Pulley, diameter	0·40 „
„ breadth	0·23 „
Revolutions per minute	950
Total weight in kilogrammes	2,610
Weight per 16-candle lamp in kilog	6·5
Floor space occupied per lamp in square metres	·0042
Capacity of dynamo, 16-candle lamps	400
Resistance of armature	·0114 ohm.
Resistance of field magnets	14 „
Electromotive force	112·47 volts.
Current	304·5 amperes.
Current absorbed in the field magnets when in circuit with a part of the regulator, in amperes	4·5
Voltamperes absorbed in the armature	1057·01
„ „ „ field magnets	490·5
„ „ „ lines, &c.	900·0
„ „ „ lamps	31800·0

V (112·47) × C (304·5) = 34247·51 voltamps

The above data holds good when the machine is running at its full power or load. One good feature in connection with the Edison machines is that each machine has two brushes for each pole, thus admitting easy adjustment without accidentally interrupting the circuit when the machine is running. Each machine is also placed upon four rails bolted upon a wooden frame, the first and last rail having an arrangement by which the machine can be shifted whilst running whenever the belts become slack, thus saving a good deal of trouble.

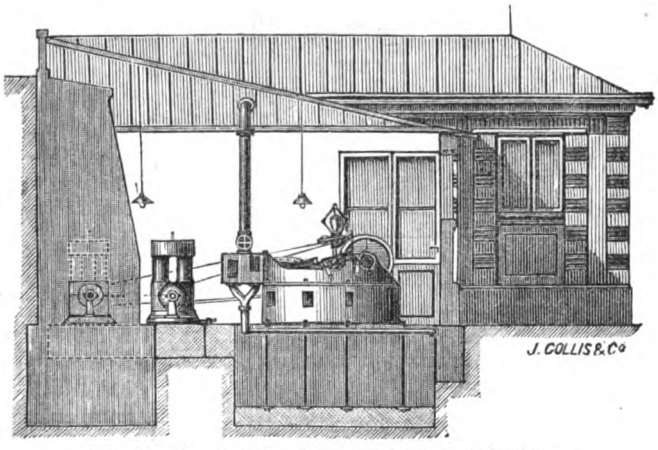

FIG. 5.—Porter-Allen Engine driving two Dynamos.

Fig. 5 shows section 2, with the Porter-Allen engine driving the two dynamo machines.

Fig. 11 is a theoretical diagram of the dynamo machine and switch-board, the heavy lines indicating the main cables from each machine, while the dotted lines represent the field circuit and connections. Fig. 10 shows one of the main plug switches and safety cut-outs combined. Fig. 9 shows the plate of lead connected between the two thumb screws of the plug switch.

Boiler House.

The boilers are two of the multitubular inexplosive boilers (system, De Naeyer and Co., of Willebroeck, Belgium). Each boiler has a capacity of 80 *force de chevaux*. Each boiler has 96 wrought iron tubes, the tubes being 4 metres long, and placed vertically in a series of eight rows, each row having 12 parallel tubes. These tubes are laid inclining towards the back and divided into compartments, so as to utilise as much as possible the heat generated below. Each boiler contains 144 square metres of heating surface. These tubes, in which the steam is generated, are connected together by coupling pieces of great simplicity and strength. The weak points in tubular boilers are the joints, which if not properly connected cause a great deal of trouble. The coupling pieces of De Naeyer, however, obviate some of the defects. They form a perfect joint and of such strength that when once connected they seldom give rise to trouble. Fig. 7 shows three pairs of tubes, vertically connected. a' are the coupling boxes, made of cast iron, having two conical ground openings. These openings correspond with the openings of the cast iron box that encases the ends of the tubes (the tubes being connected in pairs, and called an element). Fig. 8 shows the two tubes B′, the ends of which are also conical and pressed with hydraulic pressure into the openings of the cast iron box, C′, and then flanged out a little. This box, C′, is then connected to the coupling box a' by means of a small conical piece of tube D′ which fits into both openings of the box and coupling

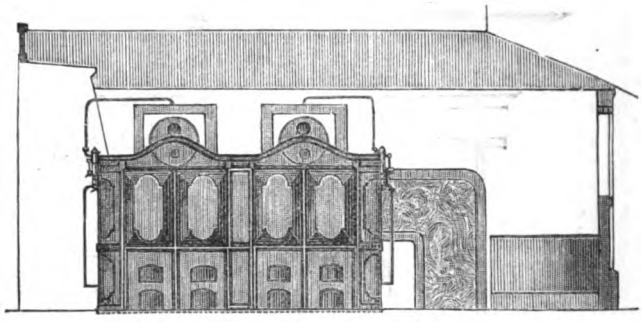

FIG. 6.—Front Elevation, Boiler House.

box. They are then locked tight by means of an iron cross piece, E′, the arms of which press into recesses made in all coupling pieces. The bolt F′ of this arm piece is introduced into a cavity cast in the box connected with the tubes, and there held firm. The locking or tightening is then effected by means of the screw at the end of the bolt. It will be seen that this forms an efficient and strong joint, and also admits

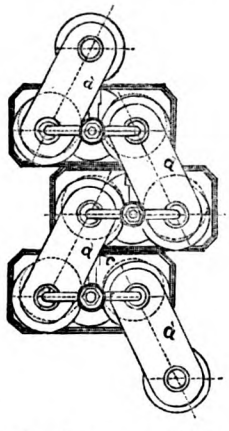

FIG. 7.—Connection of Boiler Tubes.

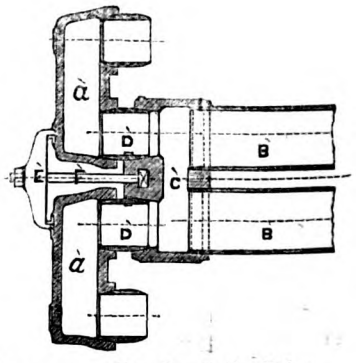

FIG. 8.—Boiler Tubes.

of easily taking apart whenever necessary for cleaning. The grate bars occupy about 3·5 metres. The steam room is 4·5 metres long, and has a diameter of 0·9 metre. The steam coming from the series of tubes enters a long strong iron box called the collector, that connects each series at their highest point. A collector resembling this one is also placed at their lowest point, making a second connection. At one of the extremities of this last-mentioned collector is attached a large faucet, used as blow-off cock. The small diameter of the tubes, considering the resistance of the iron, which is tested at 40 atmospheres, renders them almost inexplosive. Should, however, an accident through some gross carelessness occur, the result would be nothing more than the tearing of one of these tubes, without sending broadcast any fragments.

Fig. 6 represents the front view of the boiler house, and shows the canal leading from the boilers to the chimney.

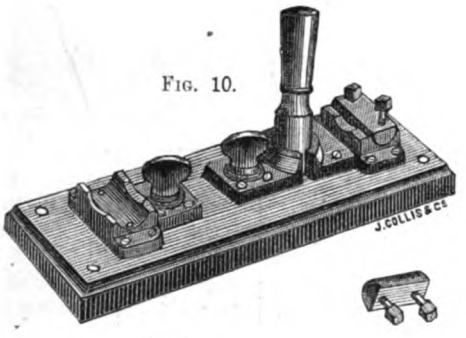
Installation inside the Theatre.

The cable leading from the main switch-board in the machine house passes to the second floor underneath the stage, and from there in a vertical direction upward to the third box or stall on the stage.

There are two objects of interest in this box—first, the grand switch-board of safety catches or plugs, and second, the regulator for the stage lights and auditorium. From this switch-board run all the principal lines carried throughout the theatre. Each of these lines has also its auxiliary cut-outs—in fact every branch, no matter if containing one or more lamps, has a cut-out with safety plugs on each pole. Table 1 shows the number of main lines, with their respective number of lamps, that run from this switch-board. The lines are all well insulated, and laid in wooden mouldings. The whole system was tested with the earth by means of a

Fig. 9.

Fig. 10.



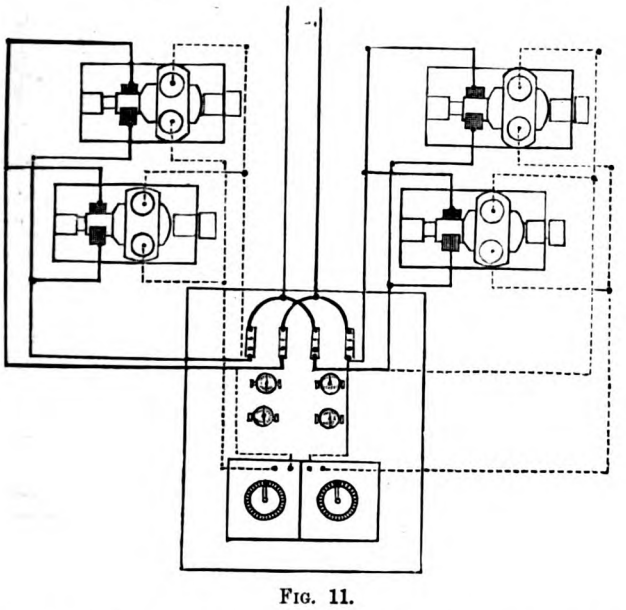


Fig. 11.

Thomson reflecting galvanometer and Wheatstone bridge, and gave a resistance of about 40,000 ohms. This is very good, considering that there are 1,921 branches.

The lamps used here are the Edison 1·08 carcel (10 candle) ones. They require 106 volts, and have a resistance at 1·08 carcels of 230·3 ohms, thus taking 0·46 ampere. The amount of copper used in conductors is about one-fourth of that used by other companies whose lamps have a resistance generally from 50 to 60 ohms hot. Table No. 2, which was made at the laboratory of the Société Electrique Edison at Ivry-sur-Seine, shows the different electromotive force, current and resistance of these lamps at various candle-powers.

Regulator.

The regulator, which is about 1·75 metre high, and two metres broad, consists of 13 switch-boards that are connected with the resistance coils, and 12 switches that serve to make connection with different lines, by means of which these lines can be connected with the regulator switches, and thus put more or less current on that line. Fig. 12 shows the regulator complete, with the lines running from it. There are 40 wires entering it, which connect and operate all lamps on the stage and auditorium (coloured lamps included). Then there are 13 cables, 10 of which each contain 20 well insulated wires that lead to the resistance coils, and which divide the coils into small detachments, thus admitting a gradual increase or diminution of resistance, which regulates the intensity of the light in that particular circuit. The other three cables each contain 30 wires serving the same purpose. The

regulator is situated in a box or stall on the stage, thus affording the person operating it a good view of the stage and auditorium. This regulator differs from the one that is installed in the Brünn Theatre, inasmuch as the one in that theatre is operated on a sort of iron counter or table, while the one here is upright, takes less space, and can be easily detached. Switch I., in Fig. 12, leads to the portable stands, which can be placed and operated from twelve different

Digitized by Google

points on the stage. These portable stands consist of a large reflector, before which is placed a battery of lamps. These lamps make their connection by means of a flexible cable leading from underneath the stage. This reflector is placed upon a stand capable of being turned in any position, and is generally used to throw a flood of light in one direction to give a more marked appearance to a certain person or thing. Switch II. leads to the side uprights, of which there are twelve pieces, or rows, each containing three lamps. Switches III. and IV. lead to the footlights. These lights are divided into two sections, the right and the left. Both these sections contain three different lines, one for the red lamps, one for the green, and one for the white. The lines are connected with the resistance coils by means of this switch, which, when pushed on the first button gives white lamps, on the second red, and on the third green. The fourth button is blank, and when pushed on, this button interrupts or breaks the line suddenly, which makes the appearance of lightning. Switches V. to X. lead and control the whole of the six crosslights.

Each of these crosslights also contains three different circuits, for white, red and green lamps. Switches XI. and XII. serve to connect and break the royal and ordinary circuits of the auditorium. It may be mentioned that all circuits in the theatre are run in such a manner that there is the same electromotive force at all points of the line—that is, between the first and last lamps on each line there is no fall of E.M.F., and may be regarded as if all lamps were connected and bunched at one point. All the switches that are connected with the resistance coils I.′, II.′, III.′., and so on to X.′, make connection with the switches above; for instance, resistance switch I′ has its connection with switch I. that puts the line in its circuit II.′ with II., and so on.

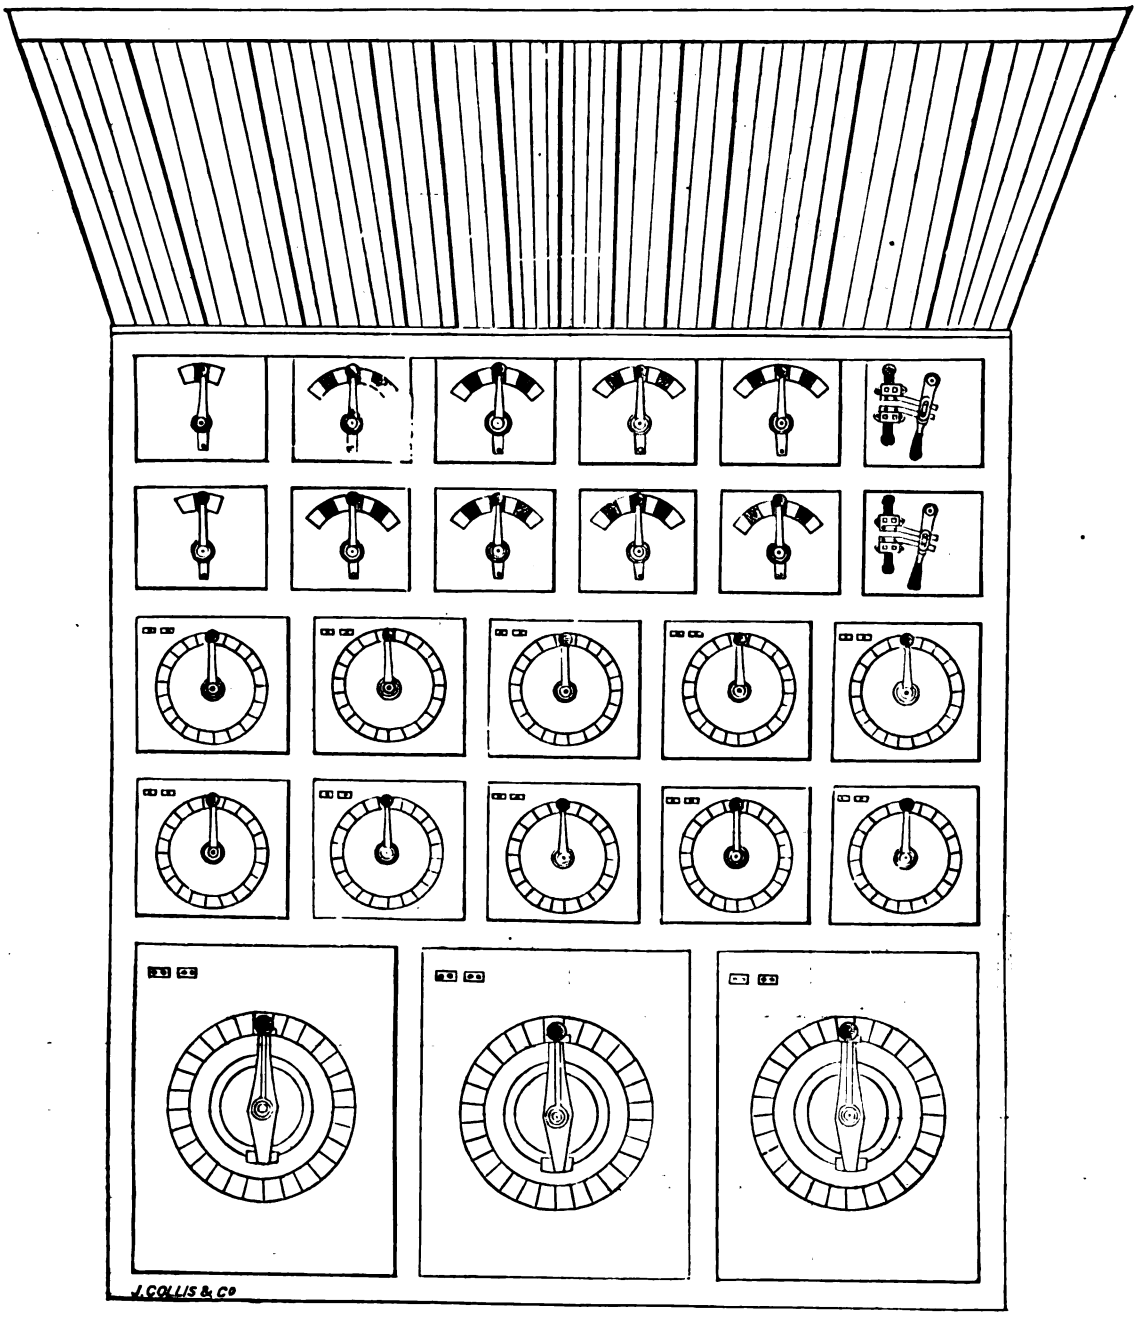

Fig. 12.—Regulator.

XI.′ and XII. control the two auditorium lines, while XIII. controls all the stage lines at one time. Thus each particular line can be regulated, or all together, at will.

There is no doubt that the installation here will be enlarged during the summer so as to light the new Palais Royal, which will require at present about 1,200 lamps. It may be mentioned that the International Brush Company have been doing some work there, and, as far as parliamentary usage will permit us to say, the authorities were dissatisfied with their work, and it was consequently handed over to the Société Electrique Edison.

ON THE CALCULATION OF MAINS FOR THE DISTRIBUTION OF ELECTRICITY.*

BY W. H. SNELL, ASSOCIATE.

(Continued from page 124.)

Group II.

It will be convenient to take next Group II., omitting Group 1A for the present. We shall probably be able to assign the mean annual usage per day for the lamps in Group II with a fair degree of accuracy in most cases. These lamps, being chiefly in public buildings, will sometimes be lit at dusk, sometimes later, and in some cases earlier, according to the character and use of the building. But there will rarely be more than one such installation upon any one section of the cable, simply because, after supplying such an installation, we should almost invariably reduce the size of the conductor. We shall therefore content ourselves in this place with a formula adapted for finding the thermal current for one such building only.

Now, in this case the number of lamps in use may be assumed to be constant throughout the (daily) period of lighting (if this is not so, at least the great majority of the lamps will be "on" or "off" together). We shall require two sub-divisions as a general rule. For week days we will write N_3 and for Sundays N_3''. To find N_3,

Let d_3 be the number of week days per annum for which the lamps will be used.

Let the average period during which the *building* (not the lamps) is in use on each of these days be from the time α to the time ω.

Let t' be the mean annual number of hours per day from dusk up to the time ω;

and t'' the same number up to the time α.

The values of t' and t'' are given in Table I., Column C.

Then we shall have

$$N_3 = \sqrt{\left\{ \frac{d_3\, n^2\, (t' - t'')}{Q} \right\}} \quad . \quad . \quad . \quad (26)$$

TABLE I.

A.	B.	C.	A.	B.	C.
p.m.			p.m.		
4:30	36	0·098	11: 0	1787·5	4·9
5: 0	91	·249	11:30	1970	5·4
5:30	151·5	·415	12: 0	2152·5	5·9
6: 0	229	·627	a.m.		
6:30	323	·9	12:30	2335	6·4
7: 0	433	1·186	1: 0	2517·5	6·9
7:30	561	1·537	2: 0	2882·5	7·9
8: 0	704	1·93	3: 0	3247·5	8·9
8:30	875	2·4	4: 0	3603	9·87
9: 0	1057·5	2·9	5: 0	3875·5	10·617
9:30	1240	3·4	6: 0	4080·5	11·18
10: 0	1422·5	3·9	7: 0	4223·0	11·57
10:30	1605	4·4	8: 0	4300·5	11·78

Column A gives the successive half-hours from 4:30 p.m. to 8 a.m. (here we take α and ω).

„ B gives the total annual period of darkness from sunset to each half-hour.

„ C gives the values of (B ÷ 365). t' and t'' are taken from this column.

Whenever α has any constant value earlier than 4:30 p.m. we shall have $t'' = o$. (This table is only correct for the latitude of Greenwich.)

As an illustration suppose that a building lit by 100 lamps is used two nights a week all the year round from 7 p.m. to 8:30 p.m., we shall have $n = 100$, $d = 104$, $t' = 2{\cdot}4$ $t'' = 1{\cdot}186$.

$$N_3 = \sqrt{\left\{ \frac{104 \times 100^2 \times 1{\cdot}214}{8{,}766} \right\}} = \sqrt{144}$$

$$\therefore N_3 = 12.$$

*Paper read before the Society of Telegraph-Engineers and Electricians.

Group Ia.

Take next Group IA. This group accounts for lamps which properly belong to Group I., but whose normal hour of extinction is at 6 p.m. or earlier. Let the required thermal current correspond to N_2 lamps; then, if we reckon as before by half-hours, there will be four terms from the earliest period of dusk (in these latitudes) to 6 p.m. The value of N_2 is therefore given by

$$N_2 = \sqrt{\left\{ \frac{d_2\,(n_1^2\, t_1 + n_2^2\, t_2 + n_3^2\, t_3 + n_4^2\, t_4)}{Q} \right\}}$$

where t_1, t_2, . . . are the first numbers in column C, Table I. It will perhaps require a moment's consideration to see that if these lamps are in use on *every* day of the year on which there is darkness before 6 p.m. we must put $d_2 = 365$; if they are not used on Sundays, $d_2 = (365 - 52)$, and so on.

It is obvious that this method of calculation might be adopted for all the "Regular" lamps, but it will be seen that it would usually involve considerably more labour in working out the results, as the coefficients of the squares of n would no longer be unity, and their proper values would also vary with the latitude.

"IRREGULAR" DIVISION.

For the "Irregular" division all that can be done is to take the best available estimate of the number of lamp-hours they may be expected to make per annum, and thence obtain a value of N_4 by means of equations (8) and (10). It seems probable that, except perhaps in residential districts, N_4 will seldom be large in comparison with the other terms of N.

Daylight Work.

It may sometimes be desirable to form another value of N, to account for the whole of the work performed during the hours of daylight. We will call this N_5, but we need not stay to consider how it should be formed.

Collation of Groups.

We have now to collate these separate terms so as to find the value of the thermal current for all the lamps upon the section. For the sake of clearness at a subsequent stage we shall write this collated value S_a. S_a, S_b, ... will therefore be the number of lamps corresponding to that part of the final thermal current in each section *which is proper to the lamps supplied directly from that section.*

Definition of "Final Thermal Current."

We reserve the term "*final* thermal current" to indicate the ultimate value of $C\varrho$, which includes the current transmitted through the particular section to sections beyond. We will afterwards show more in detail how this may be estimated in a system of conductors. The number of lamps corresponding to this final thermal current will be written ϕ_1, ϕ_2, ...

We will here collect the various terms of N for convenience of reference:—

Division (1)—"Regular" lamps—

Group I.—Lamps lit at dusk	... ...	N_1
„ I'. „	for Saturday work only...	N_1'
„ I''. „	for Sunday work only ...	N_1''
„ Ia. „	not in use after 6 p.m....	N_2
„ II. „	in public buildings (chiefly)	N_3
„ II''. „	„ for Sunday work only	N_3''

Division (2)—"Irregular" lamps ... ... N_4

„ "Daylight" work ... ... N_5

This list has a somewhat inconsequent air, but after what has been already said it will not be necessary to add any further explanation of the *raison d'être* for this classification. It is obvious that the scheme is very elastic, and that, as we have attempted to deal with the most general case, it may often be simplified in actual use.

Digitized by Google

To find S_a it will be necessary to deal with these terms successively, for it is obvious that they do not all require the same method of collation. It will be seen that the following is probably the best order :—

(1)	Combine	N_1	with	N_1'	; call the result	N_a
(2)	,,	N_a	,,	N_2	,,	N_b
(3)	,,	N_b	,,	N_3	,,	N_c
(4)	,,	N_1''	,,	N_3''	,,	N_d
(5)	,,	N_c	,,	N_d	,,	N_e
(6)	,,	N_e	,,	N_4	,,	N_f
(7)	,,	N_f	,,	N_5	,,	S_a

We have for the fundamental formula (*vide* Equation 14 *passim*)—

$$N_{(x+y)} = \sqrt{(N_x^2 + N_y^2 + A} \quad . \quad . \quad . \quad . \quad . \quad (14)$$

where $$A = \frac{2}{T}(n_1 m_1 + n_2 m_2 + \quad . \quad . \quad .).$$

(To be continued.)

SELF-MESMERISM OR SELF-HEALING.

A Mr. Harvey sends us some remarks on this subject. Amongst many other things, he says :—"All that the self-mesmerist or self-healer has to do is to sit down quietly, close the eyes, and turn his consciousness or mind everywhere within his body, probing, searching, and examining, so as to become as it were conscious of all the processes of the body, which are otherwise automatic or unconscious. Daily self-introspection and vigilance are needed. In this way through the nerves, through the circulation, and through the muscles, the self-healer forces physical force to flow as heat and muscular energy. "There should," says Mr. Harvey, " be several hospitals for self-mesmerism or self-healing." Now, if we can arrive at this desirable end whilst sitting upon our own particular doorstep, why want hospitals? If the people who threaten us with apoplexy by sending us stuff of this sort would turn their consciousness, self-introspection, vigilance, or whatever it may be, into *our* bodies, they would discover a degree of irascibility, heat, and muscular energy which might produce a decided effect could distance be annihilated.

ON ELECTRIC TRAM CARS.*

BY A. RECKENZAUN.

It may be premature to read a paper on the subject of electric tram cars, considering that at this moment there is only one such car in existence in this country, as far as the author is aware ; this solitary example, moreover, has only been in operation experimentally since October last, therefore the invitation of the council of this institute was accepted with a considerable amount of hesitation. The Inventors' Institute has a privilege before other societies in this respect, that it will judge of the merits of an invention as an invention apart from the commercial aspect of the problem. Utility, however, is the first desideratum in an invention, and the author now submits to this institute the first question of utility. Before going into the details of our subject it may be interesting to dwell for a moment upon the figures in this table, which was prepared in order to show what power a pair of horses are capable of exerting.

Power exerted by two horses in pulling a car with passengers, weighing 4½ tons, tractive force 30lb. per ton :—

At 7 miles per hour on level road			2·52	horse-power.
,, 6 ,, ,,	,,	.....	2·16	,,
,, 6 ,, ,,	gradient	1 in 75.....	4·32	,,
,, 5 ,, ,,	,,	1 in 37.....	5·4	,,
,, 4 ,, ,,	,,	1 in 37.....	4·32	,,
,, 3 ,, ,,	,,	1 in 25.....	4·32	,,
,, 4 ,, ,,	,,	1 in 25.....	5·76	,,
,, 5 ,, ,,	,,	1 in 25.....	7·2	,,
,, 3 ,, ,,	,,	1 in 18.....	5·4	,,

The additional power necessary to pull a car round curves cannot be ascertained with the same accuracy. It depends upon the radius of the curve, the amount of play in the axle boxes, and the size of the wheel flanges. A flexible wheel base will considerably facilitate the movement on curved roads, and wet rails offer less resistance than dry ones. The force required to start a car and to get up speed is necessarily greater than the force required to maintain the speed uniformly. It is a variable quantity, says Mr. D. K. Clark in his admirable book on tramways, for it may be anything that horses choose to exert. But it has been found by experiment that the momentary starting force is about four times the tractive force when once in motion ; thus we may form a rough idea as to the exertion of a horse in starting a car on the level or on an incline. Horses cannot tell us of their sufferings, we know merely that their life in tramway service is short, although they do not work longer than 3 to 4 hours a day. It seems barbarous to use horses as these figures show ; still, there has been no economical substitute until recently, and it is only within the last few years that mechanical traction has made any headway. That mechanical power will supersede animal power, and that at no distant date, is admitted on all hands, and the question of the kind of mechanical power to be employed is still an open one. It is often asked why so much mechanical power is required for the propulsion of tram cars, and why it is necessary that a tramway locomotive should be made to give as much as 40 indicated horse-power, whilst 2 horses seem to do the same amount of work. The above table shows what mechanical work is actually being done. James Watt ascertained experimentally that a strong dray horse was capable of producing a continuous effect of 33,000 foot pounds per minute, but we see that one tram horse does the work of three dray horses very frequently. When we now consider that a tramway steam locomotive weighs from eight to ten tons without the car and passengers, it becomes evident that the indicated horse-power just given is no extravagant measure. Take a locomotive engine, car and passengers, weighing together fourteen tons ; in order to move that load on a level road with 30lb. tractive force per ton and at a speed of seven miles an hour we require between seven and eight actual horse-power, which is equivalent, after allowing for engine friction, to about eleven indicated horse-power, and in travelling up an incline of 1 in 37 this power will amount to something like thirty-four indicated horse-power. Reducing our figures to a coefficient and maintaining that the tractive force is 30lb. per ton on a level but dirty road, we come to the conclusion that when moving at the rate of seven miles per hour on a straight line we consume in round numbers eight foot pounds of work per minute for every pound weight on the rails, on an incline of 1 in 75 we consume sixteen foot pounds, and on an incline of 1 in 37 twenty-four foot pounds for every pound weight carried at the same speed. Therefore it is of the utmost importance to reduce the dead weight to be propelled to a minimum. Where a locomotive engine has to drag the car behind it it becomes necessary to provide weight in order to obtain good adhesion on the rails, and the best plan no doubt would be to utilise the weight of the car and passengers to furnish the requisite adhesion. The number of steam locomotives employed in tramways is daily increasing, and steam traction is gaining in public favour. It is not within the range of this paper to examine into the advantages or disadvantages of steam traction, but merely to show whether electric cars have any chance of success from a utilitarian point of view. We distinguish between the terms electric car and electric tramway or railway ; the electric car carries its energy within, and it is quite independent of external influences, whereas with electric tramways the energy (electricity) is conveyed from the generating station to the rails or other conductors communicating with the motor which turns the car wheels. Separate conductors are used by Messrs. Siemens and Traill at Giant's Causeway and elsewhere. Mr. Magnus Volk, at Brighton, conveys the current through the rails. The nature of the ground on the Brighton beach does not allow of any accumulation of wet and dirt, the rails are above the level, and there is no traffic across the line. An electric tramway is now being constructed at Blackpool, where the current of electricity is to be conveyed through conductors in a pipe laid underground. This pipe has a slot throughout the whole length to permit of the connection between the car motor and the conductor beneath the surface of the road. Our electric tram car requires no conducting medium. It does not interfere with the rails or roadway, nor with other traffic, it can be readily shifted from one line to another of the same gauge, and it can be run in conjunction with the horse cars.

The Battery.—The first requisite for an electric car is a battery, which can be stowed away within the car. Such battery has to be of small weight, it must be reliable, supply any quantity of current according to the requirements of the road, and it must be cheaper to maintain than horseflesh, and emit no smell. Primary batteries were out of the question ; the cost of zinc and acids consumed in them would be much greater than the cost of animal power, independent of the difficulties attending the process of refilling such batteries when exhausted. The invention of the secondary or storage battery put the question entirely in a new light. Certain successful laboratory experiments at once suggested the adaptability of this invention to the propulsion of vehicles. Four years have elapsed since the introduction of the Faure accumulator into this country ; it caused quite a sensation at that time, and money could be found in abundance for the exploitation of anything that bore an electrical name. Things have changed entirely since then. The original Faure battery has never been of any practical service, and very substantial improvements had to be made, at enormous costs, to bring the secondary battery to a commercial value. The Electrical Power Storage Company have acquired the patent rights of M. Faure, in addition to those of Messrs. Sellon, Swan, and Volckmar, and they have step by step improved the mechanical details of these secondary batteries till they arrived, after fearful labours and expenses, at what may be termed a thoroughly practical article. But the prejudices created in the public mind by early failures have not quite worn off yet, and it will require something wonderful and startling to convince the public that the work of the last four years has produced remarkable improvements. None but those who have been intimately connected with the manufac-

* Paper read at the Inventors' Institute, May 18, 1885, Mr. C. E. Spagnoletti, President of the Society of Telegraph Engineers and Electricians, in the chair.

Digitized by Google

ture of storage batteries can form an idea as to the numerous difficulties which had to be surmounted before a permanent success was obtained. The battery was long ago perfect from a theoretical point of view, but it could not stand the test of time. Time was an essential factor; it took many months to test the durability of a set of cells, and it was only by close observation and careful remedying of defects one by one as they appeared that the storage battery assumed its present form, simple as it may appear to the uninitiated. The cell before you is one of a set of the type specially designed for tram car work. In a lead-lined strong teak box are placed 21 lead plates, weighing together 26lbs., inclusive of connecting strips and terminals; ten of these are called positive and 11 negative. Each plate is formed of a lead grid, the perforations of which are filled with a paste of lead oxide; the positive plates contain thin red lead, which in charging is converted into peroxide, and the negative grids are filled with a paste of litharge, which in charging is reduced to spongy lead capable of absorbing hydrogen. We store, therefore, not electricity, but oxygen and hydrogen, which gases, by discharging the battery, manifest themselves externally in the form of electrical energy. This box is filled with sulphuric acid and water at a specific gravity of about 1,150 deg.; then a lid is put on, sealed all round the edges to prevent any spilling of acid. This acid is never removed so long as the battery lasts. There is no reduction of lead or any material going on within the cell, and the battery would last for ever but for the fact that the lead grid of the positive plates becomes so brittle with oxidation that it crumbles to pieces in the course of time; then these positive plates have to be replaced periodically by new ones, but the old lead is valuable. The life of a positive plate depends entirely upon the amount of work it has done. The plates in the box before you have been at work since September last year, and they are still in excellent condition, I should say they are still as good as new; they have frequently been discharged at the rate of 100 amperes, whilst the average working current is 46 amperes. These cells are always being charged at the rate of 32 amperes, and the storage capacity of a cell is 150 ampere hours. Sixty such cells will weigh 1¼ ton, and propel a car with 46 passengers for about 2 hours over a road with ordinary inclines, curves, and 60 stoppages per hour. The diagram represents a car which has been running at Millwall and at Battersea. The accumulators are placed on trays under the seats, out of sight. These trays can be drawn out through doors at one end of the car, and replaced speedily. A trolly containing a fresh set on trays and rollers is drawn up to the end of the car. The discharged cells are pulled out all together by means of a small winch, and the newly-charged ones pushed in, when the car is ready to proceed on its journey. There are three sets of accumulators to each car—two sets charging whilst one set propels the vehicle; thereby time is saved and waiting prevented.

The Electro-motor.—This machine has to convert the electric current into mechanical power. For tram car propulsion it is absolutely necessary that the motor should have a high efficiency, and at the same time be of small dimensions and little weight. To combine these requirements has been the aim of the author, and he has at length produced a machine (shown on the diagram), which has had some rough tests in actual service under the most trying circumstances and conditions. There are two motors driving the car, each capable of working up to nearly 9 horse power, and weighing 420lbs. Each motor is supported independently upon a small bogie, the whole mechanism is self-contained, and each separate bogie forms a small locomotive engine upon which the car rests. One axle of each bogie is a driving axle; thus we obtain four small driving wheels, which give the requisite grip upon the rails. Either bogie can be detached from the car in less than one hour, so that in case of repairs and inspection the motor can be taken out and replaced without letting the whole car stand stand idle for any length of time.

The Gearing.—The speed of the motors is necessarily high—about 1,000 revolutions when the car runs at seven miles per hour; thus it is necessary to introduce some mechanical reducing gear between the motor shaft and the driving axle. The gearing employed consists of a worm on each motor shaft, and worm wheels on the driving axles, giving a ratio of about 1 in 12. The worm gearing is boxed in, likewise the motor, and the wheels run in oil; dirt is thereby excluded, and the lubrication perfect. Easy access is obtained to the motors and lubricators through doors in the floor of the car.

Variation of Speed and Power.—This is obtained by means of a compound switch, which arranges the motor circuits, so that the machines shall work in series, in parallel, or singly. Thus, the resistance of the circuit being varied, the power and the speed vary accordingly. When a greater range of speed is desirable, the motor circuits are still further divided by arranging the field magnet wires apart from the armatures. This obviates cumbersome gearing, which would add to the weight and expense, increase first cost, as well as maintenance. The driver has full command over the motive power; one handle suffices for all the operations of starting, stopping, and varying the speed or power. There is no useless electrical resistance, and therefore no waste of energy, whatever speed the car may be travelling at. The car is provided with these details at both ends, so that the driver has merely to remove the handles and two connections at the end of a journey, and then proceed. It would be an easy matter to vary the speed by decreasing or increasing the number of cells, and thereby vary the electromotive force. This method, however, is injurious to the accumulators, because some of the cells would be discharged sooner than the others, and when they are all recharged in series, some would have to be very much overcharged before the rest could receive their share. There would not only be a waste of power occasioned by the evolution of gases for no purpose, but the life of the cells and their efficiency are reduced by this irregular treatment.

Brake Power.—At each platform there is the usual vertical shaft and brake handle. A chain is wound upon this shaft when the handle is turned and eight brake blocks are simultaneously pressed against the corresponding number of wheels. The car can be stopped in an instant. Besides this there is an electrical brake, so that the motors act as dynamos driven by the momentum of the car, or running down an incline; the whole of the power stored up in the momentum of the car is converted into electricity, and the current generated is utilised in magnetising the brake blocks, thereby increasing their grip upon the wheel tyres. Arrangements are being made to render this electric brake automatic, so that the main circuit will be broken and the brake circuit with the motors closed automatically when the speed of the car reaches a certain maximum.

Cost of Motive Power.—It has been mentioned that the capacity of the tram car cell is 150 ampere hours. We do not exhaust them entirely, but leave a margin of about 20 per cent. in the cells, 120 ampere hours' charge being sufficient to propel the car full of passengers for two hours, or about 12 miles, over an average road with frequent stoppages. When charging 60 cells at the rate of 32 amperes for four hours, and replacing the accumulators in the car every two hours, we require steam power to the amount of about 15 indicated horse-power per car. Assuming that the car has to run 72 miles in a day, and that we are supplying several cars at the same time from one engine, the fuel consumed need not exceed 4lb. per indicated horse-power per hour. The charging takes place during 12 hours of the day only; thus 7cwt. of coal per car per day will give a consumption of about 10lb. of coal per mile. Reckoning the price of coal at 18s. per ton, the fuel per car mile would cost less than one penny. By working longer hours we could do with less engine-power, but, of course, with the same consumption of coals per car mile. The most economical steam tramway locomotives burn from 9 to 12lb. of coal per mile, or about the same as quoted for the electric car. There are two reasons for this high consumption—firstly, the steam locomotive weighs four times as much as the accumulators, electric motor, and driving gear, therefore it requires greater power for its own propulsion; and secondly, a tramway locomotive boiler and engine cannot be expected to compete with a large stationary engine and boiler as regards economy. Thus the loss arising from the conversion of steam power into electricity, and the re-conversion of electricity into mechanical power, is more than compensated for by corresponding advantages. There are instances when water power is available within a reasonable distance from the tramway depôt, and in such instances the additional economy will be apparent.

Prime Cost, Maintenance, and Depreciation.—The steam engine, boilers, dynamos and shafting, and all necessary apparatus for a charging station, to supply a dozen electric cars, including spare power, will cost £4,000; and the complete equipment of 12 two-horse cars, inclusive of ample spare gear, may be estimated at £6,000. The superintendence of machinery at the charging station will cost £1,100 per annum; fuel (at 18s. the ton), water, oil, and waste, £1,400; 10 per cent. depreciation on engines, boiler, and dynamos, £400; and with an estimated depreciation of 35 per cent. on the whole propelling apparatus, we get a total expenditure of £5,000 per annum, which is equivalent to 3·5 pence per car mile run. You will observe that these figures are thoroughly reasonable, and allow of a good margin. We should have to almost annihilate the whole concern at the end of a year in order to bring the working costs to an amount allowed by some tramway companies for horsing.

The following is a summary of the principal points in favour of this system:—

1. Economy in running cost.
2. The electric car has the same appearance as those in general use, and any ordinary car can be readily converted.
3. The wearing parts of the mechanism driving the wheels are few in number and easily replaced.
4. The weight of the motive power is less than two tons, distributed over two small bogies.
5. The propelling apparatus is invisible to the passengers, practically noiseless, clean, and free from danger.
6. One man (not necessarily skilled) can drive the car.
7. The car may be illuminated at night by the electric current, sufficiently to enable the passengers to read comfortably. The power required to maintain the electric light is so small that the cost may be neglected from the estimates, for the lamps (giving together 40 candle-power) consume only three ampere hours out of 150 given by the cells.
8. The maintenance of the permanent way (paving) must be less than in the case of tramways where horses are used, the hoofs of which follow always in the same tracks.
9. The space required for a charging station for the secondary batteries is much less than that necessary for stables for horses to do the same work.
10. The same plant which charges the storage batteries may be utilised for lighting the depôt and even buildings in the neighbourhood.

Discussion.

Professor George Forbes, F.R.S.E., gave a short and concise account of the electric railways laid down in various parts of the world within the last few years, and he considered the methods of conveying the electricity through rails or other conductors clumsy and unsatisfactory. In Mr. Reckenzaun's tram cars they had no stationary engine connected with it by a conductor, and this he considered, other things being equal, a very great advantage. After the experiments made by M. Philippart with tram cars propelled by a Faure battery, he was glad to hear Mr. Reckenzaun say that storage batteries had at last been made commercially useful and practical. He now believed the difficulties which had encountered secondary battery makers in the past had been surmounted, and that the method of constructing them had been so enormously improved, that those who used them were now masters of the situation, instead of *vice versâ*. Pointing to the battery exhibited on the table, the speaker said every one was struck with its light weight, which was brought about by its being made of thin plates, thus giving a large surface and a greater current than had ever

PRIMER OF ELECTRICITY, No. 28.

SUBMARINE TELEGRAPH CABLES: THE INSULATION TEST.

(Copyright, 1885. By A. E. BAINES.)

The following is presented to our Readers as a specimen of the Primers of Electricity published at "The Electrician" Office, price 1s., post free 1s. 3d.; in boards 1s. 6d., post free, 1s. 9d. The book will be found of great assistance to young Electricians, and has already been received with much favour by the English and American public. The Second Edition is now ready:—

THE non-conducting materials commonly employed for the purpose of insulating the copper strand of a submarine telegraph cable, or, in other words, to prevent the dissipation of the electric current into the water, are india rubber and gutta percha, or amalgams of which one of these bodies forms a constituent part. Theoretically speaking, neither are absolute *non-conductors*, but their conducting power is so low that it may, in comparison with the high conductivity of metals, be considered, for all practical uses, as non-existent. India rubber is an excellent insulator, is plastic, and as such is peculiarly suitable for office leads, &c., but it possesses several disadvantages which somewhat restrict its use. Unlike gutta percha, which improves with prolonged submersion, it has a tendency to deteriorate under certain circumstances, into which I need not at present enter, and it is therefore inferior to gutta percha for the object we have in view. In the following remarks, whenever reference is made to the dielectric or insulating portion of the cable, that reference will be to gutta percha. In Primer No. 26, on the constant of the astatic galvanometer, we have seen, from the example given in that paper, the resistance in ohms represented by a deflection of one degree of arc, *i.e.*, by one division of the galvanometer scale. That resistance was 50,000,000 ohms. In this test the conditions will be the same as those for the constant, with the exception that the unknown insulation resistance (x) of the cable is here substituted for the known artificial resistance (R) of 100,000 ohms, and an earth is used on the battery instead of a return wire as before.

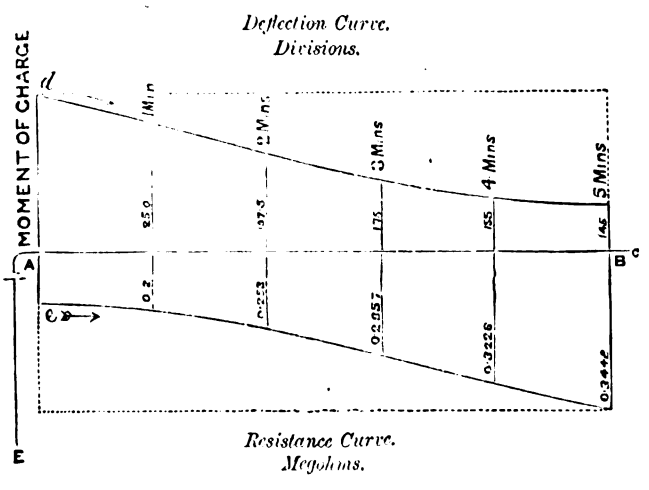

FIG. 1.

Having the above diagram in view, let the base line c be the length, 1,000 miles of a submarine cable—extending between two stations, A and B—whose insulation resistance it is required to measure. The curve d shows the process of electrification of the cable, indicated by the readings at the end of each minute, while the curve e gives the gradual increase of resistance at the end of each similar period; the ordinates in each case being in accordance with the example given below.

We shall suppose the current to be applied at the testing station A, the other end of the cable, at B, being freed or insulated, as by suspension in the air. The practical connections at A, together with instructions for taking the test, are given in Fig. 2. One pole of the battery is put to earth, a lever of the testing key a (Fig. 2) is depressed, and the circuit completed by the imperfect insulation of the gutta percha covering of the cable, which allows a certain portion of the current to escape to earth throughout its whole length. We will now presume that, after having allowed the usual 20 seconds interval between charge and observation to elapse, the galvanometer has been put into circuit by opening the short circuit key b (Fig. 2), and we are prepared to read the deflections registered on the scale of the galvanometer at the end of every consecutive fifteen seconds during a period of five

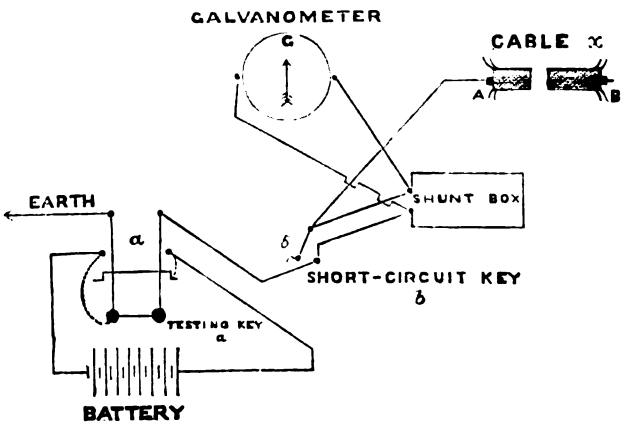

FIG. 2.

INSTRUCTIONS.—Close short-circuit key b, so as not to injure the galvanometer by the sudden rush of the current into the cable; put on current, by depressing one lever of the testing key a at any 60″; allow about 20″ to elapse, then put galvanometer in circuit by opening b, gradually.

NOTE.—This latter is best done by tapping the key until the deflection is fairly steady.

minutes. A gradual fall in these deflections will be observed (Fig. 1) until the cable has received its full charge, when the registration will remain comparatively steady. This is due in a great measure to the porosity of the gutta percha, which absorbs the current until its thousands of minute cells or pores have, in a manner of speaking, become saturated. In a short cable this process would be almost instantaneous, but in one of 1,000 miles in length the major portion of five minutes is the usual time taken up by the process of

NOTES.

SOUTH AFRICA.—The Cape Assembly has approved the construction of an alternative telegraph cable.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending June 30, amounted to £4,200.

THE ELECTRIC LIGHT IN VIENNA.—The Baumgarten Restaurant, near Vienna, has received an installation of Klostermann arc lamps.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 3rd inst. amounted to £2,670.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of June, 1885, were £1,333, against £1,336 in the corresponding period of last year.

THE INDIAN TELEGRAPHS.—The telegraph from Moulmein to Myawaddy, on the Siamese frontier, a distance of 75 miles, joining the Siamese line from Bangkok, will, it is believed, be finished before the coming dry season.

THE CANADIAN TELEGRAPHS.—It is stated that the Dominion Government intend to at once construct a telegraph line connecting Edmonton and Calgary, two important centres of industry in the north-west territories.

THE ELECTRIC LIGHT IN CANADA.—A successful installation of a 200-light incandescent plant has been put down in the College of Ottawa, Ottawa, Ont. This is the first educational institution in Canada to adopt the electric light.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June amounted to £37,846, and to £37,585 in the corresponding period of 1884; increase, £261.

THE GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company are as follow:—Receipts for June, £24,840; 1st January to 30th June, £142,840; corresponding months, 1884, £129,520; 1883, £123,480.

THE ELECTRIC LIGHTING OF A RESERVOIR.—In regard to the electric lighting of the Nottingham Park-row Reservoir, we are requested to state that the installation was put down by Oppermann Brothers, and not Oppenheim Brothers, of London.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending the 3rd inst. were £2,095, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE TELEPHONE IN MEXICO.—The Mexican Telephone Company has contracted to furnish the Government twenty-five telephones to connect the tax offices and barracks in the Federal district. Private subscribers are said to be continually increasing.

THE ELECTRIC LIGHT AND ATHLETICS.—The use of electric lights on athletic grounds has been tested for a few weeks in America, where the grounds of the Williamsburg, L.I., Athletic Club are now lighted by electric lamps. By their light games were carried out in the evening.

TELEGRAPH CONGRESS.—The head of the International Telegraph Bureau at Berne, M. Churchod, has arrived in Berlin in order to concert with the German Postmaster-General, Dr. Stephan, the final arrangements for the triennial Congress relating to International Telegraphy.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th June are £2,876, as compared with £3,131 in the corresponding period of 1884. The March receipts, estimated at £6,763, realised £6,875.

THE BAZIN ROTATIVE BATTERY.—The Bazin rotative bichromate battery has been designed by the inventor for the purposes of domestic lighting. We understand that M. Hospitalier is making exhaustive tests of this cell. M. Huon has, we believe, been appointed to represent M. Bazin in London, but he has no apparatus.

SIXPENNY TELEGRAMS.—The *Standard* understands that the statement of Lord John Manners, that an estimate existed in the Telegraph Department showing that a million would have to be spent during the next four years in consequence of the introduction of cheap telegrams, was a surprise to the late Postmaster-General. Mr. Shaw-Lefevre intends to make inquiries into the matter.

NEW INSULATING SUBSTANCE.—Messrs. Berthoud and Borel are preparing a new insulating substance in the following manner:—Linseed oil is maintained at a temperature of 300° until it acquires a brown colour and a sirupy consistence. A quantity of colophane is then added, and the mixture stirred for a time. To cover a body with an insulating coat it is plunged into the mixture at a temperature of 200°.

STORMS IN AUSTRIA.—A telegram from Vienna, dated the 6th inst., says that heavy masses of cloud collected above Austria Proper yesterday, and subsequently discharged themselves in torrents of hail and rain. Moravia, Lower Austria, Upper Austria, and Western Hungary in particular were sorely afflicted. At Ischl the lightning struck a villa and destroyed the brick work. At Pressburg the storm did great injury.

THE ELECTRIC LIGHTING OF STREETS.—At a recent meeting of the Commissioners of Sewers, notice of motion was given "That, having regard to the repeated failures of private companies to supply electricity, it is desirable that the Commission do undertake street lighting by electricity, and that it be referred to the Streets Committee to select a small area, and to obtain estimates of cost of installation." The consideration of the subject was adjourned.

MUSIC BY TELEPHONE.—On the 5th inst. began the regular transmission to the Antwerp Exhibition, by the Van Rysselberghe system, of the instrumental music played at the Vauxhall concert in the Brussels Park, a distance of fifty kilometres, or about thirty miles. The notabilities of the Telegraph Administration and of the Exhibition were present, and commented favourably on the clearness with which the sounds were reproduced.

LONG DISTANCE TELEPHONY.—It is stated that M. Sarrien, in addition to the arrangements already entered into with M. Van Rysselberghe, has authorised experiments to be made with the system of M. Tommasi. As a result of those experiments our contemporary, the *Bulletin Internationale des Téléphones* announces that a company is about to be formed with a capital of 125,000 francs for the purpose of exploiting the patents of M. Tommasi.

THE BENGAL TELEGRAPHS.—The Telegraph Department of Bengal is to be thoroughly reorganised. There will be only one grade of signallers, and promotion to telegraph masters will be by examination. The highest pay to be drawn by a signaller will be 150 rupees; telegraph masters of the first class will draw 250 rupees, and those of the second class 200 rupees. To encourage retirement amongst the older men employed in the department, the Government of India

Digitized by Google

have sanctioned service from eighteen years of age being counted for pension.

THE MORAL INFLUENCE OF ELECTRICITY.—During the course of an inquiry into the profits of publicans in the West End of London it was stated in explanation of the large sum of £5 a week being paid for mineral waters, that at the time there was a telegraphic instrument behind the bar, and people wished to keep themselves as sober as they could—that they might know the betting and the winning horses. After this statement the Blue Ribbon, which is supposed to be emblematic of the Derby, should, in common fairness, be shared with the lowly and moralising Morse.

THE TELEGRAPHS AND THE WOODSTOCK ELECTION.—We are informed that no less than 600 telegrams giving the declaration of the poll were despatched from the little post office at Woodstock on Friday evening. In addition to these Press messages to the extent of over 25,000 words were sent over the telegraph wires. On this occasion the local staff was aided by members of the special telegraphic staff from London, who worked with the Wheatstone transmitter; but during the progress of the contest some 15,000 words a night were sent over on the ordinary Morse instrument by two clerks from Oxford who had been sent to the aid of the Woodstock postmaster.

TELEGRAPHIC COPYRIGHT IN INDIA.—The Legislative Department of India have circulated for the expression of public opinion the draft of a Bill giving newspapers twenty-four hours' copyright in all news and telegrams obtained at their own cost. The Bill was generally approved by the Anglo-Indian newspapers, the only objection being that in a distant country like India the period fixed was not long enough. The native press, on the other hand, which is too poor to afford special telegrams, raised an outcry against the proposal, as calculated to deprive it of the chief source of its information, namely, the telegrams published by its wealthier contemporaries.

THE ELECTRIC LIGHT AND VEGETATION. — Mr. P. P. Dehérain has concluded that the influence of the electric light on vegetation is as follows:—The electric light contains rays which are injurious to vegetation; the greater part of these rays are kept back by transparent glass; the electric light contains, on the other hand, sufficient rays useful to vegetation to maintain the life of plants entirely under its influence for two and a-half months; this amount of useful rays is, however, insufficient to bring on young germinating plants, or to bring full-grown plants to maturity. These conclusions, if we mistake not, are somewhat at variance with those arrived at by the late Sir William Siemens.

THE ELECTRIC LIGHT IN FLOUR MILLS.—Speaking of dust explosions, a case from Germany is worthy of notice. A sack of flour, falling dowstairs, opened and scattered the contents in a cloud through the lower room, where a burning gas flame set fire to the dust, causing an explosion which lifted a part of the roof of the mill, and broke almost all the windows. There can be no doubt that the majority of dust explosions are, like mine disasters, due to open lights; and as this danger can be practically avoided by the use of the incandescent electric light, there really seems to be no valid reason why it should not be introduced more generally, as those establishments which have used it express themselves in its favour.

COMPARISONS ARE——.—The *Daily News* says:—It is a fact worth recording that the message sent by Mr. Cyrus Field to the President of the United States, on Saturday evening, occupied longer in its transmission from the Buckingham Palace Hotel to Throgmorton-street than it did in its transmission from the latter station to Washington. The time taken in sending the message to Throgmorton-street was ten minutes, while the journey through the Atlantic cable and on to Washington was performed in eight minutes. It reflects credit upon the Western Union Telegraph Company that they facilitated the transmission of the messages by connecting their Cape Breton station direct with the Executive Mansion at Washington.

RETURN OF VOLUNTEERS FROM THE SOUDAN.—The detachment of the Army Postal Corps, which was selected from the 24th Middlesex (Post Office) Rifles for service in the Soudan, arrived in London on Tuesday afternoon from Suakim, and met with a very cordial reception.—Seven provincial members lately enrolled for the purpose of joining the Reserve of Trained Telegraphists, having failed to pass the medical officer, have been struck off the strength of the regiment. The commanding officer wishes that in future intending candidates for the Reserve of Trained Telegraphists will, with their application, send a certificate of health, in order that the inconvenience caused to themselves and the regiment by such cancelling of an enrolment may be avoided.

THE POST OFFICE TELEGRAPHS.—The Press Association has obtained particulars of the extensive preparations made by the Government for the new system of sixpenny telegrams. The extensions have been made on the basis of an estimate that the reduction in tariff will cause an increase of the business of the department to the extent of 30 per cent. within the first year, and the extra expenditure already incurred amounts to half a million sterling. Of this amount £475,000 has been spent in new plant—poles, wires, instruments, &c., whilst £25,000 has been laid out in the erection of new buildings. The number of female clerks at the Post Office is now being considerably increased. For every single appointment there are about a score of applicants. There have been recently 145 vacancies in the Post Office, and for these 2,500 young women applied.

BIG GUN ILLUMINATION.—On the occasion of the *conversazione* of the Society of Arts on Friday evening last, the 14-ton gun near the main entrance of the Inventions Exhibition was a source of more than usual attraction, owing to the illumination of the interior by means of a special horizontal electric arc lamp, adapted for examination purposes by Colonel Maitland, R.A., of the Royal Gun Factory, Woolwich, and manufactured by Messrs. Johnson and Phillips. A Holmes-Burke primary battery maintained the light on this occasion, the one charge of exciting fluid with which it was supplied being not only sufficient to keep the light burning brightly and steadily throughout Friday, but also on the Saturday evening, when it was again the object of universal interest. This battery also is manufactured by Messrs. Johnson and Phillips, of Charlton, Kent.

BOOKS RECEIVED.—"Volk's Electric Railway." [Brighton: Magnus Volk.] An interesting little pamphlet has been written by Mr. Magnus Volk, on the subject of the Electric Railway at Brighton. Although not a scientific exposition of the electrical transmission of power, the little *brochure* explains in a popular and simple manner how the car is propelled, and gives much information in the form of a series of answers to questions which are continually being asked by the non-scientific and perambulatory public. These answers relate to the manner in which the car is worked; how the electricity in the rails drives the car; the action of the motor; the principle of the commutator and switch in connection, with the reversal of the current and the alteration of the speed, and so on. The little work is well worth reading, and we heartily recommend it to the notice of beginners in electrical science.

THE TELEGRAPHS BILL.—Lord John Manners is it would seem in some difficulty as to the Telegraphs Bill. He will not as a matter of probability give up free addresses, and the department cannot afford sixpenny telegrams with free addresses. The new Postmaster-General, it is understood, contends that much might be done to abridge addresses by warnings to the public and by instructions tending in the direction of brevity. But this will not avail to carry the proposal unless he can obtain the sanction of the Treasury to the prospective loss, and there, it is said, he does not meet with support from Sir Stafford Northcote or from Sir Henry Holland. According to the *Daily News*, an elaborate scheme of codification of addresses, with the object of meeting the objection (on the score of expense) to free addresses, has been brought under the notice of the Postmaster-General. If this should prove practicable, it would, says our contemporary, considerably decrease the cost of telegraphing messages.

THE EXPLOSION ON BOARD HER MAJESTY'S SHIP "VALIANT."—Some details are given of the explosion which recently occurred on the steam launch of Her Majesty's ship "Valiant," in Lough Swilly. It appears that some practice was taking place on the steam launch with what is known as a "hand charge," which in this instance consisted of 1lb. of gun cotton with some small pieces of metal, contained in a metal casing, and is used for throwing on the deck of an enemy's vessel at night. It is attached to a small detonating pistol by a light wire, the operator holding the pistol in one hand, while with the other he throws the charge. As soon as the charge lodges on the deck of the hostile vessel the pistol is discharged, and, an electric contact being made, the charge is exploded. Practice was taking place in the stern of the launch, and the operator threw the charge towards the water, but somehow the connecting wire became entangled. An effort was made to release it when the pistol went off, firing the charge. The force of the explosion was terrific.

TELEGRAMS AND CHANGE OF ADDRESS.—A correspondent of *The Times* writes as follows:—"Perhaps it is not generally known what happens when a telegram is sent to a house which the addressee (as he is called in official language) has left. As no one would be likely to guess, and as the information is important, I venture to ask you to allow me to relate my experience. A telegram from a neighbouring London district was sent to me on Friday at a house I quitted ten days ago, with these results to me and to the sender. I never received the message at all, though I am less than a mile off. The sender received a form saying that the telegram was not delivered because I was gone to my new address, which was given. The General Post Office then washed its hands of the matter, and my friend sent a servant with his message. Of course it looks as if it would have been quite as easy to post the contents of the telegram to me as to send notice to the sender of my new address, and a rather more effectual fulfilment of a contract. But this is only the aspect which the case wears to the unofficial mind."

THE PARTICULAR SERVICE SQUADRON.—A contemporary says:—"It would seem that a more perfect electric light than has yet been tried will have to be devised before a large fleet could without great risk of destruction lie at anchor for any length of time in a harbour open to an enemy's torpedo boats. The defensive boom is but a weak protection unless every yard of water can be searched by an almost continuous blaze of electric light, and that must be thrown outside the most advanced line of defence, or it becomes a danger rather than a safeguard. The 'Mercury' proved this in the fight of Monday week, when she much more frequently betrayed the movements of her own boats than succeeded in discovering what others were doing. Occasionally, however, the blinding rays from her lamp were flashed full in the face of the defenders, and that suggested how effectively a light specially contrived might be used to veil the operations of an attacking force. After long exposure to this fierce glare the eyes become so dazzled that they can see nothing for a time, and a clever foe might, in the briefest interval, manage to make a successful dash if she had thus prepared the way for it."

A NEW AMPEREMETER.—An amperemeter has been constructed by M. Heschus, consisting of a differential air-thermometer, into the two reservoirs of which are introduced the ends of wires of iron and nickel silver, soldered together. An electric current passing through these wires causes the series of solderings in one reservoir to be heated and the other series to be cooled, owing to the passage of the current being from iron to nickel silver in the one, and reversed in the other. The difference of the temperatures is accompanied by a change of atmospheric pressure in the two reservoirs, and a consequent displacement of the liquid in the manometer connecting them. Experiments made with the instruments show that Peltier's phenomenon is proportional to the strength of the current. A Grenet element gives an elongation of 4 mm. if a given unit of resistance is inserted, and with two such units 1·3 mm. Six Baudet elements give an elongation of 6 mm.; 6 elements with double the surface, 11 mm. The inventor claims advantages for his machine in its giving the intensity of the current at each moment; its cheapness, and containing no magnet to prevent its use near a dynamo; and its measurement of attenuating currents, while it may serve as a galvanometer and as a dynamometer.

THE ELECTRIC LIGHT ON THE PENNSYLVANIA RAILROAD. The Pennsylvania Railroad has been for some time experimenting with electric lighting for the purpose of introducing it permanently on its trains. For the last two months one of the regular trains between New York and Chicago has been lighted by electricity, and with eminently good results. The current is obtained from secondary batteries, which are placed under the car body. At present one of the parlour cars is supplied with eighteen of the constant current storage batteries, the total weight of which is 800 pounds. They are capable of supplying 120 ampere hours. The lamps employed are of the Bernstein type, and there are 12 lights in each car. Ten of these are 20 candle-power and two of 10 candle-power. They run at 35 volts and require 1·5 ampere for their full power. The batteries are charged at each end of the route, and are not removed from the cars. Electric leads are run to them and connection made, similar in manner to the charging of the gas reservoirs now employed. The size of each individual cell is 6″ × 9″ × 11″, so that the space occupied is very small. Several sleepers and ordinary passenger coaches are now being fitted up, the efficiency of the battery having been proved to be very high, and its construction eminently suited to the conditions under which it is used.—*Electrical World.*

HISTORY REPEATS ITSELF.—It was in 1846 that gas was introduced in Stuttgart, and a number of old women who had been employed by the Town Council to light and trim the ancient oil lamps walked in procession through the streets of the town bitterly complaining that they had been robbed of their bread and butter by the new invention. The complainants to-day are the directors of the gas companies and their shareholders. But the shouts and yells of the old lamp-

Digitized by Google

lighters in Stuttgart did no more bring back the ancient oil lamps than the deprecations of directors and shareholders of gas companies will prevent the electric light from ousting gas as a lighting material. And who but they will regret it? All will rejoice at the prospect of living, breathing, and working in rooms whose atmosphere is no longer vitiated by products of combustion, such as carbon dioxide, sulphur dioxide and others, and where the temperature is no longer artificially raised by the combustion of 85 per cent. of heat-giving gases, contained in ordinary coal gas, which we burn for the sake of its 12·15 per cent. of heavy light-giving hydrocarbons. It was a tempting task, promising a golden harvest, to find a suitable substitute for it; and in no branch of applied electricity has so much ingenuity been displayed as in the construction of the various lamps.—*Fortnightly Review.*

With the Evolutionary Squadron.—Admiral Hornby has issued to the captains and some other officers of the Particular Service Squadron a memorandum requiring them to report to him, in writing, upon a number of questions with reference to the impromptu defence of harbours. The following are some of the points of detail which are to be more especially considered:—The value of the naval electro contact mine; the efficiency of naval electro mechanical mines, and their safety in laying down and picking up; the advisability of using the same circuits for counter mining and for electro contact mines; the efficiency of the present fitting of short branches and disconnectors; whether, if separate circuits were used for electric contact mines, it would not be advisable to lay them on a multiple cable, so that each mine could be separately tested and lifted; the value of the electric light when placed on shore or in boats away from a fleet, and the best means of so placing it; the best means of defence against an attack by fast torpedo boats; the best method of mining defence for a fleet of ships from which all mining stores have been removed, but which are accompanied by one or more torpedo depot ships like the "Hecla;" the safety of such mines as the Pietraski and their value for blocking up an enemy's fleet; whether, if defensive mining stores be not carried in ships, dropping mines, such as the Pietraski, should be carried, &c.

The International Telegraph Conference.—A telegram from Berlin announces that the first meeting of the next International Telegraph Conference, which will assemble in Berlin, has been definitely fixed for the 10th prox. Most of the European and several extra European States have already notified their intention of sending delegates. Nearly all the large cable companies will also be represented. The *Standard* trusts that when the International Telegraph Convention meets it will endeavour to redress two or three grievances which the mercantile community has against the system under which messages are now taxed. One of these grievances is the rule which forces all people who live in, or who have business with, extra-European places, whose names exceed ten letters in length, to pay double price for the transmission of these names. A merchant, for example, telegraphing to or from Buenos Ayres, or any extra-European place, whose name exceeds ten letters in length, has to pay for that name as if it were two words instead of one. In Buenos Ayres alone, we are told, this means an extra tax of at least £100 per annum on telegrams as compared with Monte Video or Rosario. Abbreviation words should be allowed in these cases. Our excellent contemporary forgets or is unaware that it is open to anyone to register a code name (and address) of fewer than ten letters. It is only the negligence of the people to which it refers that has given rise to a fancied grievance.

Carpentier's Circulating Cell.—The essential part of this battery is a syphon with unequal limbs, both of which are plunged in the same vessel containing the exciting solution. In the longer limb are placed the electrodes, consisting respectively of zinc and carbon, and the syphon is filled in any convenient way. So long as the circuit remains open the liquid in the syphon remains homogeneous, and equilibrium is maintained; but as soon as the circuit is closed the zinc dissolves, and increases the density of the liquid in which it is immersed. Hydrostatic equilibrium is thus disturbed, and a circulation of the liquid is established proportional to the intensity of the current. The heavy liquid containing the zinc falls to the bottom of the vessel and remains sharply separated from the fresh solution, whilst the latter continually ascends the short limb of the syphon and is brought in contact with the electrodes. In the cell constructed by M. Carpentier the carbon electrode constitutes one limb of the syphon, and is in the form of a tube, in the centre of which is suspended the amalgamated zinc. The other limb consists of the annular space between the carbon tube and the surrounding glass envelope, communication between the two being established by means of a ring of holes pierced in the upper part of the carbon. The position of the electrodes is so arranged that the level of the exciting liquid is somewhat higher than the ring of holes. Several elements of this form may be placed in one and the same reservoir, if care be taken to isolate them sufficiently from one another by means of glass or caoutchouc envelopes with small apertures at top and bottom.

The Earthquakes.—The returns of the damage occasioned by the earthquake in Cashmere on May 13th state the loss of life at 3,081 persons, besides 25,000 sheep and goats and 8,000 cattle. The number of dwellings ruined is estimated at 75,000. A correspondent of the *Calcutta Englishman* says:—"The force of the earthquake appears to have concentrated itself at certain spots, and there to have spent itself. These spots look as though a large amount of gaseous matter under the earth had, with the strength of dynamite, been struggling for an outlet, and had torn and lacerated the ground at the point where it found an exit. Thus one sees villages with the huts destroyed, the earth adjacent being cracked and split, and the air putrescent from the bodies of cattle buried under the houses, while not 20 yards distant a sloping wooded hill seems untouched. In other places the side of a vertically scarped hill has been sliced off as if by the guillotine, the earth so severed lying at the base. Some hillsides are only partially disconnected, and a deep incision remains. Other hills again present the appearance of an ordinary landslip. Near Lalledourah village three enormous chasms have been formed, one about three-quarters of a mile broad, and 20 feet deep. Not far distant a tract of land 800 yards square has subsided, forming a trench 100 yards long, 50 feet deep, and 30 feet wide."—A severe earth-tremor has been felt in Tasmania, as well as in the colonies across the Straits. At Launceston several chimneys were thrown down or cracked, and the spire of the Scotch Church, which was affected by an earth-tremor last July, has been further displaced.—A severe shock of an earthquake has also occurred at Dongarra, Western Australia. The houses shook for some seconds, and the residents were much alarmed.

The Electric Light in New Zealand.—We have received an interesting account of the trial of an electric search-light in Dunedin. It appears that the Government, early in May last, placed in the hands of R. E. Fletcher and Co., of that city, an order for the construction of an electric search lamp, to be used in connection with the Auckland defences. Similar lamps will in

Digitized by Google

due course be supplied to the other principal ports, but in the meantime the first specimen was hurried on, and a trial was made of its power, previous to its despatch to Auckland. The apparatus was conveyed to the heights below Roslyn, in the neighbourhood of the stone quarry, so that use could be made of the Corporation engine stationed near that spot, and this engine, although rather erratic in its working, enabled a very satisfactory experiment to be made. The lamp was what is known as "hand focussing," and provided with a universal motion, so that it could be turned at pleasure by the hand in any direction. It was also fitted upon a small tripod stand, for convenience of transit. The light was projected forward in a steady powerful stream by means of a 22in. parabolic silvered reflector, and when an engine of, say, eight horse-power nominal was used, a bright light was shown to a distance of at least 1,500 yards. The illuminating power of the lamp under these conditions would be about 35,000 candles. On the occasion of the trial, an excellent idea could be obtained of its utility. When the light was directed over the town the spire of the First Church, the Town Hall, and other buildings were distinctly illuminated, whilst within a smaller radius objects were visible as clearly as in broad daylight. Similar lamps have been in use some time at the Australian ports, and there are also three in Tasmania. The idea of having those required for New Zealand manufactured in Dunedin was, however, an afterthought, and Messrs. Fletcher are to be congratulated upon the success of their first experiment.

Litigation in America.—Recently, in the Supreme Court of the United States, an appeal was tried in the case of the Western Electric Manufacturing Company *v.* the Ansonia Brass and Copper Company, in which it was decided that the appellant company's reissued patent for an improvement in insulating telegraph wires, which covers a product, fell with their original patent, which covered a process, for the following reasons :—The process consisted in compressing the wax or other suitable material into the pores of the fibrous covering of the wire without scraping off any part of it. This process was anticipated by letters patent to Dundonald and to Baudouin in this country, which describe the compressing of the wax, &c., to attain the same result, viz., the insulation of the wire. The patent was therefore declared invalid. The difference between the complainant's and the Baudouin process consisted merely in the use of a greater quantity of wax. This might be an improvement on the latter process, but it did not involve invention. The allegation of appellants that one of the features of their process was allowing the wax to cool before compressing it was not sustained by any mention of this feature in either the specification or claim of the patent. As the claim failed to describe this feature, it could not be held to be covered by the patent.—In the Circuit Court of the Southern District of New York the case of the Gold and Stock Telegraph Company *v.* the Commercial Telegraph Company *et al* has also received judgment. The facts are briefly as follow :—The complainants' reissued patent was for an improvement in telegraphic printing instruments for registering the price of gold and stocks by means of type-wheels moving independently, and arranged so as to print jointly or separately upon one strip of paper. This was construed, in view of the state of the art and in the light of the specification, to mean a united action, or action in co-operation, and not a simultaneous action, of the wheels. The defendants alleged non-infringement, for the reason that the wheels of their instrument have a locking device which prevents their moving independently, "because it is a condition of the rotation of one wheel that the other shall first be brought to a state of rest;" but this was not the sense in which the patentee used the term "independently." By it he only meant that one wheel was not linked to the other, so that both must rotate together. As defendants' instrument differed from complainant's only in respect of the locking device, the allegation of infringement was sustained. The complainants' patent, originally issued to the inventor, E. A. Callahan, was applied for in December, 1867, and bore the date of April 21, 1868. An English patent for the Callahan invention bore the date of March 16, 1868, the date of the filing of the provisional specification, and was sealed on August 21, 1868. Upon these facts it was held that the complainants' patent did not expire on March 16, 1885.

The International Telegraph Convention.—On Monday last the Duke of Richmond received at the Board of Trade an influential deputation representing the principal cable companies, on the subject of the Bill now before Parliament, to carry into effect the International Convention for the Protection of Submarine Telegraph Cables. The deputation included the Marquess of Tweeddale, Viscount Monck, Sir D. Gooch, M.P.; Mr. J. Pender, M.P.; Sir G. Elliott, Bart., M.P.; Admiral Sir George Richards, Sir James Anderson, Mr. C. Burt, Mr. Bompas, and Mr. Ford. The Duke was attended by Baron H. de Worms, M.P., Parliamentary Secretary of the Board, and by the private secretaries, Mr. A. West and Earl Cairns. The Marquess of Tweeddale represented to the Duke of Richmond that the companies were advised by several of the most eminent counsel of the day that the present law of England was more favourable to them than the law proposed by the Paris Convention. For the most part, the new Convention would satisfy the companies, but Articles 2 and 4 contained objectionable clauses, inasmuch as they were advised that if the captain of a repairing steamer broke another company's cable he might be liable to five years' imprisonment, even though he could not help breaking it while grappling for the cable he was sent to repair. It was further stated that private enterprise owned 90,000 out of the 100,000 miles of cable in existence, and £34,000,000 of the capital, and that the proposed law, which was designed to protect these enterprises, really made the position of the companies worse than it was at present. The Marquess of Tweeddale further showed that upwards of 20 foreign States were parties to this Convention, so that the captain of an English repairing steamer was liable to be tried in a foreign Court under the terms of the Convention without such protection as English laws or an English judge and jury might give him. It was also shown that this Conference, composed amongst others of such countries as the Argentine Republic, Republic of Costa Rica, Republic of Guatemala, Dominican Republic, United States of Columbia, Persia, Roumania, Servia, and the Republic of Salvador and the Republic of Uruguay, was called together by the Director-General of Telegraphs in France, none of the companies having been invited to attend or being heard on the subject. The Duke of Richmond, in replying to the deputation, reminded them that they had not interfered when the question was before the House of Commons; but the companies replied that the recent laying of the Mackay-Bennett cables had given the question a prominence which it did not possess before—so much so that they had at once obtained the advice of eminent counsel. It is hoped that the Duke of Richmond and the House of Lords will take some time to consider the matter, and not too readily ratify a Convention which has been shown by the parties concerned to be injurious to their interests. The foreign telegraph companies in England are also preparing a petition against the Bill.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(*Continued from page 116.*)

It will be convenient to express the various powers which have been dealt with in terms of the angle A B C, which is the angle by which the difference between the phases of the two electromotives forces falls short of two right angles. Call this angle θ. Also call the angle B A C ϕ, and the angle B A D β.

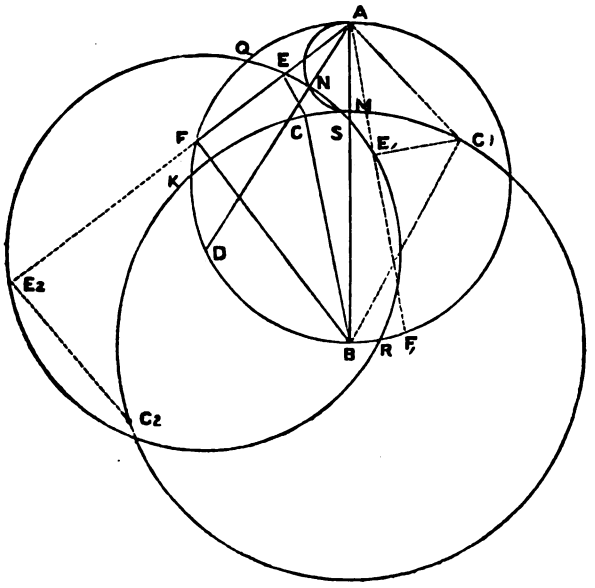

FIG. 16.

It is first to be observed that the triangles D E A, B C A are similar to each other, since each side of the former bears to some one side of the latter the ratio cos β, or geometrically,

$$A E = A C \cos \beta$$
$$E D = C B \cos \beta$$
$$D A = B A \cos \beta.$$

From the triangle A C B, A C : B C :: sin θ : sin ϕ,

or $$A C = f \frac{\sin \theta}{\sin \phi},$$

therefore $$A E = f \frac{\cos \beta \sin \theta}{\sin \phi}.$$

Also from the triangle A B C,

$$\frac{e}{f} = \frac{\sin \overline{\phi + \theta}}{\sin \phi} = \cos \theta + \cot \phi \sin \theta,$$

and from the right-angled triangle A F B

$$A F = A B \cos F A B = e \cos \overline{\phi + \beta}.$$

Hence, A F A E $= e f \cos \beta \sin \theta \frac{\cos \overline{\phi + \beta}}{\sin \phi}$

$$= e f \cos^2 \beta \sin \theta \cot \phi - e f \cos \beta \sin \theta \sin \beta$$

$$A F \; A E = e f \cos^2 \beta \left(\frac{e}{f} - \cos \theta \right) - e f \cos \beta \sin \beta \sin \theta$$

$$= e \cos \beta \{ e \cos \beta - f \cos \overline{\theta - \beta} \}.$$

Therefore, the power at work in source A being $\frac{A F \; A E}{2 R}$ is equal to

$$\frac{e^2 \cos^2 \beta - e f \cos \beta \cos \overline{\theta - \beta}}{2 R} \quad . \quad . \quad . \quad (\alpha).$$

which is in the form desired.

Again, from the triangle C E A,

$$A E = A C \cos C A E = A C \cos \beta,$$
$$\therefore A E^2 = A C^2 \cos^2 \beta,$$

and from the triangle A C B

$$A C^2 = B C^2 + A B^2 - 2 B C A B \cos A B C,$$
$$= f^2 + e^2 - 2 e f \cos \theta.$$

Hence, $A E^2 = \cos^2 \beta \{ e^2 + f^2 - 2 e f \cos \theta \}$,

or the power employed to heat the circuit, being $\frac{A E^2}{2 R}$, is equal to

$$\frac{e^2 \cos^2 \beta + f^2 \cos^2 \beta - 2 e f \cos \theta \cos^2 \beta}{2 R} \quad . \quad . \quad (\beta).$$

The difference between these two powers is the power transmitted, and therefore doing work upon source C. Hence the power transmitted is equal to

$$\frac{e f \cos \beta \cos \overline{\theta + \beta} - f^2 \cos^2 \beta}{2 R} \quad . \quad . \quad . \quad (\gamma).$$

The efficiency of the transmission is found by dividing this expression (γ) by the expression (α) for the power of source A. The efficiency therefore is equal to

$$\frac{f}{e} \left\{ \frac{e \cos \overline{\theta + \beta} - f \cos \beta}{e \cos \beta - f \cos \overline{\theta - \beta}} \right\} \quad . \quad . \quad . \quad . \quad . \quad (\delta)$$

The expression for the power of A shows that it is greatest when $\theta = \pi + \beta$, and least when $\theta = \beta$, but it is always positive so long as $e \cos \beta$ is greater than f. When this is not the case it is possible for the source A to have work done upon it.

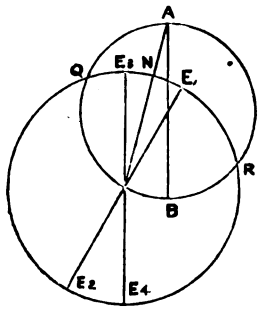

FIG. 17.

In Figure 17, let A B $= e$, and the angle B A D $= \beta$. B D A is a circle upon AB as diameter, whose centre is K. Let D be the centre of the circle which is the locus of E of former figures, cutting B D A in Q and R as before, and A D and A D produced in N and P. Join D K and produce it both ways to cut this circle in E_1 and E_2, the point K being in D E_1. Also draw E_4 D E_3 parallel to B A, cutting the same circle in E_4 and E_3, E_3 D A being equal to β.

Then A D E_3 is the angle giving the value of θ when the power exerted by the source A is least, and A D E_4 (greater than π) is the value of θ for the greatest power of A.

The expression for the transmitted power working on C given by equation (γ) shows that that power is greatest when $\theta = -\beta$, *i.e*, A D E_1 is the value of θ for this condition, and when $\theta = \pi - \beta$, *i.e.*, A D E_2, the power working on C is negative and a minimum, *i.e.*, C *would have to do its greatest work*.

The circle which E describes is now divided in the important points Q R E_1 E_2 E_3 E_4, and from the above considerations we can discuss the question of the stability very conveniently. We shall suppose E to move round in the positive direction.

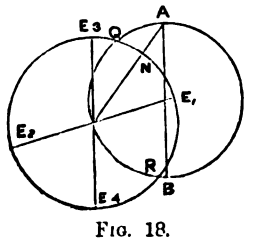

FIG. 18.

As regards the point E_3, it may be observed that if D N is sufficiently great, it will lie outside the circle A D B (as in Fig. 18). The condition that it does not do so is expressed by the inequality $\frac{f}{e}$ must be less than $\frac{\cos 2\beta}{\cos \beta}$ which will be first supposed to be the case. As E moves from E_1 to Q, there

Digitized by Google

will be transmission of power to C, from its maximum value at E_1 to zero at Q. Hence, as regards C the motion will be stable, because a retardation of its motion is accompanied by a greater transmission of power to it, and *vice versâ*.

As E moves from Q to E_2, C will do work from zero at Q to its maximum value at E_2.

Hence the motion of C will be stable, because a retardation of its motion is accompanied by a smaller duty, and *vice versâ*.

As E moves from E_2 to R and finally to E_1 there will be instability as regards C.

Again, as regards the source A. As E moves from E_3 to E_4 through E_2 the power exerted rises from its minimum at E_3 to its maximum at E_4. Hence in this half circle the motion of A will be unstable, because any retardation on its part, implying an advance of E, will be accompanied by a greater duty, and *vice versâ*, so that the displacement will be augmented.

As E moves from E_4 to E_3 through R, the power exerted by A diminishes from its maximum to its minimum value. Hence, in this half circle the motion of A will be stable, because any retardation on its part, implying an advance of E, will be accompanied by a smaller duty, and *vice versâ*, so that the displacement is decreased.

Hence between E_1 and E_3 there is absolute stability for both sources, and between E_2 and E_4 absolute instability.

In the remaining regions there would arise a necessity for constraint in one or other of the sources.

Between E_3 and E_2 the source A would need constraint, between E_4 and E_1 the source C would need it.

If both sources are constrained a position of E between E_2 and E_4 becomes a possibility.

Under the conditions, therefore, represented by Fig. 17 it would appear impossible to make both sources do work at the same time without constraint; but this impossibility arises from the fact that E_3 is nearer to N than Q is. When Q is nearer to N than E_3 is, *i.e.*, when $\frac{f}{e} > \frac{\cos 2\beta}{\cos \beta}$, the impossibility is removed, and of the power going to heat the circuit part is provided by each source.

The result may be compared with that furnished by either source working alone, which would be for the sources A and C, $\frac{e^2 \cos^2 \beta}{2R}$ and $\frac{f^2 \cos^2 \beta}{2R}$ respectively, assuming that the other source is constrained to remain at rest.

When both are acting the total power is

$$\frac{e^2 \cos^2 \beta + f^2 \cos^2 \beta - 2ef \cos \theta \cos^2 \beta}{2R}.$$

Hence the gain, if any exist, compared with A working alone is

$$\frac{f^2 \cos^2 \beta - 2ef \cos \theta \cos^2 \beta}{2R}.$$

$$= \frac{f \cos^2 \beta}{2R} \left\{ f - 2e \cos \theta \right\}.$$

For an advantage, therefore, $\frac{f}{e} > 2 \cos \theta$.

Now, θ must be less than β for stability.

Hence an advantage appears possible if $\frac{f}{e} > 2 \cos \beta$, a narrower restriction than $\frac{f}{e} > \frac{\cos 2\beta}{\cos \beta}$, necessary that both sources should do work, with stability.

Both conditions are approached by increasing the value of β, *i.e.*, by increasing the coefficient of self-induction. It is, therefore, only with a comparatively large value of the coefficient of self induction that the stable doing of work by both sources is *possible*, and with a still larger value that it would be *advantageous*.

As to the transmission of power, its possibility is seen to depend upon the value of the angle $E_1 D E_3$, which is simply 2β. The closer E is to E_1 the greater will be the transmission, but it must be remembered that a retardation of E from its normal position between E_1 and E_3 to an equal distance behind E_1 will upset the motion. Thus it will not be desirable to press too closely to the maximum transmission. If E is situated at the point N, the efficiency is not at its maximum value, but it has the value $\frac{f}{e}$, which is the greatest efficiency in transmission with uniform currents. It would thus appear that transmission by alternating currents does not compare unfavourably with that by uniform currents in this respect.

(To be con'inued.)

MORE LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Is electric lighting to have yet another sin laid to its charge? We have had Stock Exchange, parliamentary, and municipal jobbery in abundance, but it now appears that to all these must be added that of combined expert and commercial jobbery. The following will explain my meaning, and is a true story:—

Some two years ago a gentleman (a partner in an electrical firm) suggested to a friend of his, the principal of a very large semi-public institution, the advisability of adopting the electric light. He went to some trouble, and showed him several installations, with the result that at last the principal induced his managing Board to vote the funds for the installation of the light, but with the proviso that the job should be put up for public tender. This was rather hard lines on our friend, who looked upon the job as in some sort belonging to him; but as he knew all the ins and outs of the proposed installation, which was a very peculiar one, he being very intimately acquainted with the requirements of the institution in question, he made sure of obtaining the contract. In due course all tenders went in, and then the managing Board wanted an adviser, being entirely untechnical. They therefore searched everywhere for a competent expert, and finally looking in the *Court Journal*, picked out their man. Unfortunately, they did not know that he was connected with one of the tenderers; but such being the case, he went through the pile of tenders, picking out four which were the only ones of value. At the head of this list, as regards low price, stood our friend's firm, that of the expert's friend being a very bad fourth; but, nevertheless, the *unprejudiced adviser* formulated a lengthy report wherein he stated that the firm who were so far out should be allowed to have their tender back to amend, as they had included machinery, &c., which the others had not estimated for. This was done. Of course, it came back £20 less than the amount of our friend's tender, with the natural result that the aforementioned upright judge's friend got the contract, our original friend who started the matter, and whose tender was lowest, being left out in the cold. All the above could be proved, and comment is needless, but if the publication of this letter will prevent such sharp practice in future its purpose will have been served.—Yours, &c.,

DAMOCLES.

[We are of the opinion that when facts of this kind can be authenticated they should be published, and further, notwithstanding the question of libel, the names should be given, so that for the future those who act in the manner described may be left severely to themselves.—ED. *E.*]

AN ELECTRIC "FRONT SIGHT."—An electric front sight for rifles has been patented by Mr. W. Winans, of Brighton, Sussex. The invention is designed to overcome the difficulty of shooting in the early morning, when the light is not good enough to see the ordinary fixed sight properly. This temporary front sight consists of a very small incandescent or glow lamp (something like a dentist's), covered with a metal shield. The shield has a small hole in it through which the light shines, and this spot of light, being turned towards the shooter, is used as the "bead" of the front sight in aiming; a small electric battery in the stock of the rifle generates the electricity for the lamp. The invention promises to be of use to the sportsman, but it will be found, we think, rather a bother in practice.

ANSWER TO CORRESPONDENT.

G. F.—*Yes. Exhaustive information upon the subject of the proper diameter of wires to be used in electric lighting has appeared from time to time in our columns.*

THE SUBMARINE CABLES PROTECTION BILL.

We mentioned last week the Submarine Cables Bill as one of the measures which would probably survive the political crisis. But we also pointed out in a general way that telegraphy and other electrical interests were, on the whole, in better plight now that the political colour of the home Government had changed. Not that we predicted anything in regard to the future; our intention was rather to offer consolation for the present, together with some reasons for hope, even in the unexpected contingency of a return of the present Ministers to office in the autumn.

It would almost seem that in one quarter at least a lively sense of some present obtainable advantage had quickly manifested itself without any prompting from us. Possibly the deputation from the Cable Companies which waited upon the President of the Board of Trade on Monday last may have been arranged with his predecessor; we cannot speak as to that; but we confidently assert that its reception would have been different, and its results, if more decisive, less satisfactory. What the representatives of the Cables asked for was that the Bill, which is in its final stages, may be referred to a Committee, so that the parties most interested may have an opportunity of being heard. What the answer of the late President would have been it is not hard to conjecture. What the Duke of Richmond urged was, not that, being the owners of vast property, the deputation had no right to be heard, but simply that the request came rather late in the day, which is certainly true, and that to put the Bill into Committee now would be to sacrifice it for the present Session altogether, which is probable. The question, then, is, will it be worth while to abandon the Bill, so as to have an amended version of it next year more in accordance with the views of the Cable Companies?

We have no hesitation in saying that if they consider, after due deliberation, that the framing of the existing clauses is dangerously ambiguous, the Companies will be justified in delaying the enactment till next year. By the Convention of Paris the British Government is pledged to enact the penal measures agreed upon there, so that the Bill is not finally endangered. In some form or other it must pass next year at latest; if in the interval the opportunity for amending it will counterbalance the evil of delay, there can be no doubt as to the course that should be taken, for if it is passed in the present Session there will be small chance of amending it in the next. There is, however, one other alternative—namely, the rejection of the Convention itself; and as at present advised, the Companies are rather of opinion that their interests are better safeguarded under existing English law than they would be under the stipulations laid down by the twenty foreign plenipotentiaries in Paris last year.

The Companies have two substantial grievances in this matter. The Convention was a French idea, and it proceeded on purely French principles. Submarine Cables were objects of international concern, therefore the French Government took them under its special and distinguished consideration. As none of the nations convened, save one, had any great pecuniary interest in Submarine Cables, they not unnaturally jumped at the idea of assuming the *quasi* rights of ownership or guardianship over them; and the one exception, the British, as usual, complacently followed suit to please its very dear friends the French. It does not seem to have occurred to the latter—and our own Government took no great pains to enlighten them—that the Submarine Telegraph Cables of the world were almost wholly the private property of British subjects. Of the 100,000 miles of cable, 90,000 belong not to States, but to individuals; and every mile of them has been laid by Englishmen. Yet the terms of the Convention for the regulation and protection of these properties were virtually framed by a French Administration, and the owners themselves had absolutely no voice in the proceedings. The British representatives on the Convention were Government Officials who took no counsel with the parties most interested.

This is grievance number one; the second is, that in legislating to carry out the objects of the Convention the home Government have similarly neglected to acquaint themselves with the real needs of the parties for whom they were legislating. So true is this, that no sooner do the proprietors get a chance of being listened to than they point out several instances of ambiguity and unfairness which the Bill, as it stands, is guilty of, solely because those who understand the subject best have not been consulted. For example, repairers of Cables will run the risk of penal servitude under the rigorous enactments of the Bill if another owner's Cable is wilfully or negligently broken or injured in repairing operations. Seeing that numbers of Cables have been laid across each other, and that the repair of the lower ones—those first laid—may involve injury or breakage to the ones above, some clearer definition of wilfulness and negligence is decidedly called for. As we pointed out in our article commenting on the Convention in the month of May last year, it is a great achievement to have established the principle of ownership, and of international protection for these Cables, and consequently of legal criminality for wilful damage done to property so owned and protected. But it is a heavy price to pay for such favours if the owners themselves are unavoidably to become the first offenders unless they are to refrain altogether from keeping their Cables in repair.

Digitized by Google

There are other, if less serious, objections to the Bill as at present worded, and it is no answer to them to say that a jury will determine the questions left in doubt. As a matter of fact juries are directed to find according to law, and are not allowed to amend Acts of Parliament in the Law Courts. We also think that the Duke of Richmond underrates the freedom of action left to each Government under the Convention. Article XII. runs as follows, "The high contracting parties engage to take, or to propose to their respective legislatures, the necessary measures for ensuring the execution of the present Convention, and especially for punishing by either fine or imprisonment, or both, those who contravene the provisions of Articles II., V., and VI." The offences referred to in these clauses are indicated with sufficient plainness; but they are not defined with legal exactness; nor, it seems to us, is their any international obligation to follow the literal wording of the Convention whilst faithfully carrying out its intentions. Article IV., which the deputation particularly object to, is not especially emphasised for legislation in the Convention. It would be better to refuse ratification altogether rather than allow this Article to be embodied in English law.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You have been publishing of late a series of very interesting papers on the subject of secondary batteries, the substance of which agrees very well with my continued experiments and investigations. I notice, however, in your last issue a sentence in the reproduction of Mr. Reckenzaun's paper which I cannot let pass without some rectification, not on account of the implied criticisms on my personal work, but on behalf of pure truth. The sentence runs thus—

"The original Faure battery has never been of any practical service, and very substantial improvements had to be made at enormous cost to bring the secondary battery to a commercial value."

It is easy to understand that practice would bring improvements in the way of applying the lead oxides upon the lead plates, whether perforated or not, but I cannot see what else has been done by the E.P.S. Company, except it be that instead of applying the lead mixture upon the whole surface of the plate they filled the holes only. This certainly saves the cost of the felt or asbestos board I used, but at the cost of an enormous increase in the electrical resistance of the cell and the prompt destruction of the uncovered part of the perforated plate. The original storage capacity of one horse-power hour has also not been maintained with certainty in 40 kilogs.—Yours, &c., C. A. FAURE.

St. Brice, Seine et Oise, France, July 7, 1885.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Though I do not like to differ from such an authority as Mr. Desmond FitzGerald, I must do so in the question as to whether sulphate of lead is formed when a secondary cell is discharged. Mr. FitzGerald argues that a sesquioxide of lead is formed. This is a doubtful, unstable compound, if it exists at all, and it cannot exist in the presence of sulphuric acid, as lead peroxide and lead sulphate would be formed. The high electromotive force of the secondary battery shows that there are very powerful chemical affinities at work, and the mere change of degree of oxidation can hardly produce such an effect. I feel no doubt that the action of the battery is due to the affinity of the Pb for the SO_4, the equations being, on one side $2PbO_2 + 2H_2SO_4 = 2PbSO_4 + 2H_2O + O_2$, on the other $Pb_2 + 2H_2SO_4 + O_2 = 2PbSO_4 + 2H_2O$. The appearance of the coating of an ordinary discharged peroxide plate does not prove the absence of sulphate, for only a very small proportion can be sulphate. Some years ago, when I made a large number of experiments on batteries, I found that in no case more than six or seven per cent. of the coating is used, even when the cell is completely run down. The expansion of the peroxide of lead in becoming sulphate perhaps blocks the coating up. The specific gravities of the oxides being taken, gave roughly the following volumes for 100 volumes of metallic lead:—Litharge 151, red lead 148, peroxide 160, sulphate 297. The formation of sulphate can be shown by using the impervious form of peroxide, as on discharging a thin white film appears on the surface only. On the spongy lead plate, again, the appearance cannot be taken as a guide, but if sulphate of lead is not formed, what is? We know that no oxide of lead but peroxide can exist in the presence of sulphuric acid. Probably only a small percentage of of the spongy coating can ever be made available. The difficulty of reducing ordinary precipitated lead sulphate has misled many people. This substance is a very troublesome insulator, and it seems to be a question of contacts. I have passed electricity through a cell with this sulphate for five weeks without reducing more than a few particles; but if a little red lead or litharge is mixed with it it reduces quite easily. A very white coating of lead sulphate on a Planté plate reduces perfectly.

Peroxide of lead can easily be made from precipitated lead sulphate, but it is too loose for battery coatings, owing to the small volume of the particles of peroxide formed.—Yours, &c.,

JAS. SWINBURNE.

36 and 37, Bermondsey-street, S.E.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the last issue of your journal Mr. FitzGerald controverts the now generally-accepted explanation of the chemical changes involved in the discharge of a secondary cell, and puts forward the idea that the unstable Pb_2O_3, which, as chemists well know, is decomposed by weak acids, and therefore could hardly be expected to exist in a secondary cell containing sulphuric acid, is formed by the reduction of the PbO_2 on the negative plate. The writer, however, gives no experimental data for his conclusion.

Some three years ago Dr. Gladstone and I communicated to *Nature* our results in elucidation of the chemical changes involved in the charging and discharging of secondary cells. One of the conclusions to which these results led was that both the peroxide of the negative plate and the finely-divided lead of the positive were converted into lead sulphate during discharge. Since these investigations were published I have found that the amount of sulphuric acid which actually passes from solution in the discharge of a secondary cell substantially agrees with the amount calculated from the equation deduced from our observations, which not only confirms our conclusion, but shows that Mr. FitzGerald's speculation has no foundation in fact.

In the case of cells where peroxide of lead is in contact with lead, I have found a greater disappearance of acid than our equation allows, but the interpretation of such a result is easy, since we know that such cells discharge themselves more or less by local action.—Yours, &c., ALFRED TRIBE.

Dulwich College, 9th July, 1885.

POTENTIAL DIFFERENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I hope to meet your correspondent's views as concisely as possible.

The law of Dr. G. S. Ohm may be stated comprehensively thus. The current in a circuit varies as the algebraical sum of all the separate sources of E.M.F., and inversely as the sum of all the resistances in that circuit.

Further, between any two points in a circuit the current varies as the difference of potential between those points plus the algebraical sum of all E.M.F.'s acting between them, and inversely as the sum of the resistances between them.

Thus V and V^1 being the potentials at the points, ΣR the total resistance between them, and ΣE the algebraical sum of E.M.F.'s acting between them, we have

$$C = \frac{V - V^1 + \Sigma E}{\Sigma R}$$

(E.M.F.'s positive in direction of current, and *vice versâ*.)

Digitized by Google

If there is no additional source of E.M.F. between the two points, we have simply

$$C = \frac{V - V^1}{\Sigma R} \quad (\Sigma E \text{ being } nil.)$$

and when a complete closed circuit is considered we have

$$C = \frac{\Sigma E}{\Sigma R} \quad (V \text{ and } V^1 \text{ being equal}).$$

It is certainly advisable when symbols are employed to know what they mean. A move has been made lately to introduce a universal notation; but as so many terms, each with their own subdivisions, now exist, the difficulty seems to lie in the scarcity of symbols. It suffices, however, to use any symbols, *provided* it is stated at the time what they are intended to mean. I see no reason for surprise that any single letter should stand briefly for the difference of potential between the ends of a resistance, if it be distinctly stated at the outset to bear that meaning.

Of course if the meaning assigned is ignored and another one substituted, a fine field is opened for discussion of imaginary points, and a "confused mind" can then easily take E.M.F. and difference of potential as the same thing, or imagine others to do so.—Yours, &c.,

H. D. WILKINSON.

School of Electrical Engineering, Hanover-square.

THE ELECTRIC LIGHT FOR MINES AND HOUSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "Electricity," as *The Times* very truly observed when commenting the other day on the disastrous Clifton Hall Colliery explosion, "is the one illuminating medium which can supply the light which miners want, without the flame which endangers them;" and the writer added that "the public cannot compel, though it may encourage, scientific brains to exert themselves as keenly for the illumination of a murky, dirty coal pit, as for the transformation of a plot of ground in South Kensington into fairy land."

As "one who knows" how thoroughly the progress of novel applications of electricity is at the present time paralysed by the want of encouragement from the public, I would venture to emphasise the gentle hint conveyed in this last paragraph, and to quote so practical an authority as Mr. Hammond, who, at the winding-up meeting of his company on the 17th of last month, gave as the reason of their inability to light Lombard-street and the immediately surrounding streets of the City (notwithstanding the exceptionally favourable conditions they had secured), that no one could now be persuaded to subscribe £100 towards carrying out electrical installations. "There were many persons," he said, "who were greatly interested in the electric light, but it had some deadly enemies who believed that every man connected with it was a thief."

The reaction against the large electric light companies is unreasonable when extended to electricity itself. But the public does not discriminate; it lost money through the blind rush which it made a few years ago, *ergo* electricity is moonshine and a failure.

But if central stations throughout London will probably be postponed for some time to come, then there is all the more reason for examining and encouraging other means for introducing the beautiful and wholesome light of incandescent lamps, not alone into murky mines, but also into the well-furnished houses of those who reside in the neighbourhood of the South Kensington fairy land; and that such means do exist is a fact of which I should wish to mention one example.

A gentleman residing in one of the handsome houses in Queen's-gate has, during the past two months, had his dining room floor most effectively lighted by means of a small primary battery located in the cellar under the pavement of the street. It is contained in three small boxes, each of which can be easily and conveniently charged or discharged in a few minutes by any unskilled person.

There are seven incandescent lamps in the hall, nine in the dining room, four in one sitting room, and three in another; each can be separately lighted or all simultaneously, and the intensity of the light can be raised or lowered just as with gas. Besides these there is one movable lamp attached to a long silk-covered double bell wire, and employed, as a miner might use such a lamp, for searching into shaded corners, or for more closely examining the beautiful pictures which hang upon the walls of the dining room.

Here, then, is an electrical current produced without engine power of any kind, without noise, without skilled labour, at very little more cost than gas in London, and by means of a handy apparatus, which a couple of miners could easily move forward from time to time, following the progress of their work. One such box, three or four feet long, and about a foot square, will supply 20 miners each with a small lighted lamp of three or four candle-power, at distances ranging up to 20 or 30 yards from the box.

At the house at Queen's-gate it produces a more brilliant light in lamps of about 15 candle power, of which the steadiness and constancy is absolutely perfect, fitted on electroliers (artistically and exquisitely designed by Osler, of Oxford-street), which make it inimitably effective for drawing room or dining room lighting.

But just now the British public seems to be as unwilling to encourage, as it is unable to compel, scientific men to produce any electrical novelty, for it taboos the inventors; and, strange to say, it is a foreigner whose house is so charmingly lighted in Queen's-gate.

Inventors, according to Virgil, will find their reward beside the poets in Elysium—

> "Quique pii vates et Phœbo digna locuti;
> Inventas aut qui vitam excoluere per artes."

—Yours, &c., M. I. C. E.

July 2nd.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note your reprint of the discussion which has been going on in *The Times* relative to the electric lighting of collieries. As I have been engaged during the past nine years in the introduction of electrical apparatus to collieries, perhaps my views on the subject may be of interest. We have already introduced the electric light underground into two large collieries, and on the surface in several others; and in one of the former, at the time the lights were put in, they were placed in many situations where no naked lights were at that time allowed to be used, with very good results. We are now about to fit up a third colliery in the north, and there are others in this and other districts that have been lighted by other firms.

It will readily be understood that, under the circumstances, I should be the last to place any difficulties in the way of its general adoption, which, I hope, will not take long to accomplish. At the same time, I think Lord Thurlow is taking a rather too *couleur de rose* view of the question. There *are* considerable mechanical and scientific difficulties in the way of its adoption in many parts of the mine, but principally at the working face, where it would be of most value in every respect. In this district especially—South Wales—falls of roof are of constant occurrence, even on some of the main roads; while at the face of the coal, in every mine, the ground is constantly changing. The face itself is constantly moving forward as the coal is worked, and the operation of getting the coal involves in most cases the falling of huge masses, so that no fixed light would be of the slightest value, or could live long. To complicate the matter there is always the danger of a spark passing when wires are broken, as they inevitably would be.

On the other hand, no primary battery or accumulator has yet been produced of such a weight that the miner could carry it, of such a size that he can place it in positions where he now hangs his safety lamp, and, at the same time, that will give him a light that will be of service to him and last the time he requires, which should be close upon ten hours, allowing for the time going to and from his work.

By dint of reducing the amount of light on the one hand and its duration on the other, a few fairly portable lamps have been produced, but they can hardly be called practical miners' working safety lamps. There is no difficulty whatever

Digitized by Google

in lighting the main roads, pit bottoms, &c., as though there may still be a slight element of danger, it is hardly appreciable, and not to be considered in comparison with other constant sources of danger that are always present. Remembering that it is necessary that there shall be a certain mixture of gas and air in a certain part of the mine, which is constantly swept by a very strong current of air, that a spark shall take place at the point where the gaseous mixture has accumulated; seeing that, except in the case of a rare accident, there is no chance for a spark to pass, and further that it shall pass *through* the gas, the conditions usually being that the gaseous mixture rises to the roof, while the lamp is kept fairly low down—remembering all these necessary conditions before an ignition can take place, where the lamps are not exposed to falls of roof, &c., while there is absolutely no other danger from the use of the incandescent light, I think that we may fairly call it, for safe positions, mechanically, a perfectly safe lamp; but for the face of the coal, where it is most wanted, much remains to be done before we can hope to see it generally adopted there. In my opinion the future lighting of the working face will be by means of lamps attached to supply wires led to a convenient point near, and not by means of portable lamps, unless a radical improvement takes place in the form and duration of accumulators. Our greatest hope lays, in my opinion, in the spread of the rudiments of electrical knowledge among those who have to use the light. This must be, especially in this case, a question of time; but once the working collier realises the fact that he can have a *good* light, better than anything he has ever dreamt of, by merely attaching a couple of small wires to other wires near, and the other ends of these wires to the lamp, he will not be long in availing himself of it; and he may be safely trusted in the large majority of cases to keep his lamp and wires out of harm's way, as soon as he understands that an accidental breakage may mean the loss of his light, and consequent stoppage of his work.

I presume that I need hardly dwell upon the other advantages of the light; but one point may be interesting. An electrically lighted colliery is invariably well lighted; whereas, with every other illuminant, so far as my experience goes, the reverse is the case. Moreover, as an illuminant, the incandescent lamp lends itself to conditions, such as strong draughts of air, that no other does; and it is *so* convenient and can be arranged *so* easily.

One more point. Lord Thurlow hints at legislation to render the adoption of the electric light underground compulsory. If I may be allowed, I would most strongly deprecate such a measure as unjust to colliery owners, and unwise in the interests of the electric light itself.

My experience is that colliery owners, above all others, are ready to adopt a new thing and to give it a fair trial once it can be shown that it is in a practical form. In the early days of the adoption of new things, however, there are too often failures through the promoters of the novelty being insufficiently posted in the difficulties they have to encounter.

In the early days of electric signalling in mines there were many failures from this cause, with the result that in a large number of cases their adoption was retarded for a number of years.

What we, who believe in the future of the electric light, and who hope to see it generally adopted, not only in mines but in factories and in our own homes, have to do is to work steadily on, meeting and conquering the difficulties as they arise, not shutting our eyes to them. By doing this I am confident that we need have no fear of the result, and that we shall need no such extraneous aids as compulsory legislation. That is my experience in the past, and I am full of confidence for the future.—Yours, &c., SYDNEY F. WALKER.

Cardiff, July 4, 1885.

COLLIERY EXPLOSIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the interesting correspondence on this subject which you reprinted from *The Times* last week, primary batteries were alluded to by Mr. Radcliffe Ward, and incandescent lamps of 20 candle-power were spoken of by Lord Thurlow, as suitable for lighting mines with safety. Miners would, however, be quite satisfied with lamps of from two to three candle-power, and primary batteries for lighting such lamps could be made of a very portable and convenient size, because no more than six or seven large cells would be required to furnish a score of miners each with a lighted incandescent lamp, protected from breakage by a small cage of wood or wire gauze, with which they could move about at distances ranging up to 20 or 30 yards from the battery.

The light so supplied would cost less than half the price of candles, or, at an equal cost, the miners might be provided with more than double the amount of light they have when using candles, as the following figures, based upon working experience with my primary battery, will show.

A primary battery now in use and supplying to the lamps an average current of 385 watts per hour when worked for five hours daily—each lamp taking 1 ampere and 24 volts—will light 16 lamps of 10 candle-power, or furnish an amount of light equal to 160 sperm candles. (The smaller lamps of 2½ candle-power require only 1 ampere and 6 volts per lamp.)

This battery is refreshed daily with 1½ gallon of solution, costing 1s. 7½d. per diem, or at the rate of £29. 13s. 1½d. per annum, and consumes zinc at the rate of 2½lb. per diem, costing, at 16s. 4d. per cwt., £6. 13s. per annum.

The maximum annual cost of the electric light in the house in question (supposing the lamps to be kept alight for five hours daily throughout the year, or for 1,825 hours per annum) would be as follows:—

Cost of acids	£29	13	1½
Cost of zinc	6	13	0
Renewal of the lamps	3	4	0
Interest and depreciation of battery (prime cost £30), say	5	9	10½
Total cost of sixteen lamps of 10 candle-power, five hours daily, or for the light of 160 candles during 1,825 hours per annum	£45	0	0

This amount of light is equal to what would be obtained in a mine by burning 160 tallow candles daily for 365 days, or a total of 58,400 candles, which, *at one halfpenny each*, would cost *£121. 13s. 4d. per annum.*

It may be interesting to add a comparison of the cost of the above-mentioned sixteen incandescent lamps of 10 candle-power with that of an equal number of ordinary "fish-tail" burners (No. 4), which most lovers of the electric light would consider to have less illuminating power than incandescent lamps of 10 candle-power.

The cost of gaslight, as it is usually supplied, viz., in fishtail burners, is habitually under-estimated, for each burner, under the ordinary pressure of $\frac{20}{10}$ths, consumes at the rate of 10 cubic feet of gas per hour (as I am prepared to substantiate).

We have therefore: 16 fishtail burners consume in five hours 800 cubic feet of gas, and $365 \times 800 = 292{,}000$ cubic feet, at 3s. per 1,000 cubic feet, cost the consumer *£43. 16s. per annum*, to which must be added the rent of the meter and leakage.—Yours, &c., O. C. D. ROSS.

15 and 17, Relf-road, Peckham Rye, S.E.,
July 7th, 1885.

[We insert this letter because of the importance of the subject. Of course our readers will understand that the figures are Mr. Ross's own; and it is evident, moreover, that that gentleman has not fully considered many of the difficulties which will necessarily attend the use of primary batteries for the purpose set forth.—ED. *E.*]

LIGHTING THE CITY OF LIEGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We notice in your paper this week a reference to an alleged offer made by the Thomson-Houston Company to light the city of Liege gratuitously for a time. We beg to say that this is not correct, and are glad that our company is not reduced to the level of many European companies who are often willing

Digitized by Google

to put in plant and run it for the sake of being able to point to their numerous (fictitious ?) contracts.

With respect to the present case, however, the matter stands thus :—A tender for 400 arcs has been sent in, with the proviso that to commence with the company would run 45 arcs for three months for nothing, provided the city would at the end of that time buy the 400 light plant at the tender price, should the lamps and machine have run satisfactorily for the three months, but that if their performance did not come up to promise they would take up their plant and walk.

This they are prepared to do, not only in Liege, but in any city on this side the Atlantic where business is meant.—Yours, &c.,

LAING, WHARTON, AND DOWN.

8 and 9, Holborn-viaduct, July 6, 1885.

ON THE CALCULATION OF MAINS FOR THE DISTRIBUTION OF ELECTRICITY.*

BY W. H. SNELL, ASSOCIATE.

(Continued from page 146.)

The accuracy of our results in each case will now depend, as far as this process is concerned, upon the accuracy with which we can find the value of A. In some cases, as in the first, this can be done very completely. We will now go through these cases in succession.

(1) N_1 *with* N_1'.—These groups can never run contemporaneously. Therefore we have A = *o*, and the formula reduces to

$$N_a = \sqrt{(N_1^2 + N_1'^2)} \quad . \quad . \quad . \quad . \quad . \quad (29)$$

(2) N_a *with* N_2.—By means of Table I., find the total annual number of lamp-hours for this group (IA.), and put this equal to $m\,q_r$ where q is the total number of hours of running per annum. The value of q may be obtained from column B ; if the lamps are not in use on every day of the week, it must be multiplied by the proper fraction ($\frac{6}{7}$ or $\frac{5}{7}$, &c.) Now, during the whole annual period of q hours during which Group IA. is at work, the number of lamps burning in Group I. remains constant at its first value, equal to n_1. If we assume (as will most usually be the case) that no work is performed by Group II. during this period, we shall have

$$N_b = \sqrt{\left(N_a^2 + N_2^2 + \frac{2\,n_1\,m\,q}{Q}\right)} \quad . \quad . \quad . \quad . \quad (30)$$

(3) N_b *with* N_3.—This case is a little more complex. Assume, first, that the section has only one installation belonging to Group II. As before, let α and ω represent the respective times of use and disuse of the building ; and let t' be the mean annual number of hours per day from dusk up to time α, and t'' the same up to time ω. Also put

$$p = \frac{n_\alpha + \ldots . n_\omega}{\omega - \alpha + 1}.$$

So that p is the arithmetical mean of the successive values of n (for Group I.) during the time $(\omega - \alpha)$; these terms of n will be taken from the table formed for Group I.

Then we shall have

$$A = \frac{2\,(t' - t'')\,d_3\,m\,p}{Q}.$$

If α = 8 p.m., or any later hour, we shall get

$$(t' - t'') = (\omega - \alpha).$$

This is also the case when the lamps are always lit at the given hour, α, whether there is still daylight or not.

Thus, for one installation in Group II.,

$$N_c = \sqrt{\left\{N_b^2 + N_3^2 + \frac{2\,(t' - t'')\,d_3\,m\,p}{Q}\right\}} \quad . \quad . \quad . \quad (31)$$

Take, now, the case in which there is more than one such installation upon the section.

Let $k_1, k_2, \ldots$ be the actual numbers of lamps in each, and let $K_1, K_2 \ldots$ be the numbers corresponding to the thermal currents which have been found for each respectively. If, as might possibly happen, these installations are regularly used concurrently, or very nearly so, we should merely have to put

$$N_3 = K_1 + K_2 + \ldots$$

and

$$m = k_1 + k_2 + \ldots$$

and to insert these values in (31). In the more general case the expression for A will have the form—

$$A = \frac{2}{Q}\Big(d_1\,t_1\,k_1\,p_1 + d_2\,t_2\,k_2\,p_2 + \ldots\ \delta_1\,t_{01}\,k_1\,k_2 + \ldots .$$
$$\Delta_1\,t_{001}\,k_1\,k_2\,k_3 + \ldots .\Big) \quad . \quad . \quad (32)$$

where $d_1, d_2, \ldots$ is the total number of days of running for each installation per annum ; $\delta_1, \delta_2, \ldots$ is the number of days on which each (possible) pair of installations run together ; $\Delta_1, \Delta_2, \ldots$ is the number of days on which each set of three installations run together ; and so on. Also $t_1, t_2 \ldots$ are the values of $(t' - t'')$ for each installation ; $t_{01}, t_{02}, \ldots$ are the values of $(t^{\text{III.}} - t^{\text{IV.}})$ for each pair of installations, where $t^{\text{IV.}}$ is found in Table I. for the time when the two installations *begin* to be running together (that is, the time corresponding to α for the later of the two), and $t^{\text{III.}}$ is found for the earlier of the two values of ω. $t_{001}, t_{002}, \ldots$ are similar values found in the same way for every three installations ; and so on.

By a similar development of equation (26) we should get for the value of N_3 an expression of the form

$$N_3 = \sqrt{\left[\frac{1}{Q}\left\{d_1\,t_1\,k_1^2 + \ldots\ \delta_1\,t_{01}\,(k_1 + k_2)^2 + \ldots\right\}\right]} \quad (33)$$

(4) N_1'' *with* N_3''.—This case is the same as the last, being the Sunday work for the same groups.

(5) N_c *with* N_d.—This case is similar to case (1), collating the total Sunday work with the week day work.

(6) N_e *with* N_4.—This case deals with the "Irregular" lamps; it is therefore impossible to obtain any definite value for A, and we can only make a choice for N_f between the limiting values.

(7) N_f *with* N_5.—N_5 being the "daylight work" the periods are exclusive, and we have

$$S_a = \sqrt{(N_f^2 + N_5^2)}.$$

Having thus obtained the values of the thermal current proper to each separate section of the system, we have now to find the "final thermal current" when the section is considered *in situ* and (unless a terminal section) transmits current to sections beyond. In the case when any given section transmits *the whole* of the current for one or any number of sections beyond, there is no difficulty in determining at least the limiting values of the final thermal current by the formulæ already considered. Now, in his recent Cantor lectures, Professor Forbes has shown that the above condition is a characteristic of *any* system in which the highest economy is attained. Referring to the "network" system, where the current has more than one path to a given lamp, he says "we should [in this case] have to choose our conductors exactly of the same size as we have chosen them here, and should have exactly the same conditions. If our conductors were chosen of the proper size for the current flowing, then the current would in that case [the 'network'] flow along exactly the same channels as under the system I have been describing [the 'multiple tree' system]. That would be the case when we had the maximum number of lamps on."

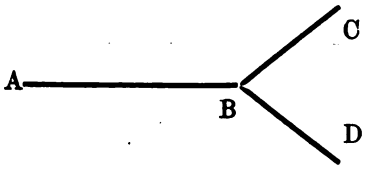
In this last sentence, if the size of the conductor is based upon the value of the thermal current, we may, I think, venture to insert the expression $\phi\sqrt{\frac{T}{t}}$ in place of the "maximum number ;" $\phi\sqrt{\frac{T}{t}}$ being the number of lamps corresponding to the final thermal current when the period is reduced from T to t hours ; t being the mean daily period during which the major part of the work is done, as in (8) and (11). Thus this

*Paper read before the Society of Telegraph-Engineers and Electricians.

Digitized by Google

expression is very nearly the mean number of lamps which burn together.

It will therefore be sufficient to consider as a type the case in which two terminal sections, B C and B D, unite with the section A B.



Let the "proper thermal current" for B C correspond to S_1 lamps, that for B D to S_2 lamps, and for A B to S_3 lamps, then we shall have for the numbers corresponding to the final thermal currents,

$$\phi_1 = S_1; \qquad \phi_2 = S_2$$

$$\phi_3 = \sqrt{(S_3^2 + x^2 + B)},$$

where $$x = \sqrt{(\phi_1^2 + \phi_2^2 + A)};$$

so that $$\phi_3 = \sqrt{(S_3^2 + \phi_1^2 + \phi_2^2 + A + B)}.$$

And if the number of lamps alight in each half-hour (from 6 p.m.) be for B C, $p_1, p_2, \ldots$; for B D, $q_1, q_2 \ldots$; and for A B, $u_1, u_2, \ldots$ we shall have

$$A = \frac{1}{T}\{p_1 q_1 + p_2 q_2 + \ldots\}$$

(the coefficient reduces to $\frac{1}{T}$ because the values of p and q are for half-hours); and also

$$B = \frac{1}{T}\{u_1 (p_1 + q_1) + u_2 (p_2 + q_2) + \ldots\}$$

(To be continued.)

PHYSICAL SOCIETY.

At a recent meeting of this society the following papers were read:—

"*On the Winding of Voltmeters.*" By Profs. W. E. Ayrton and John Perry.—As it is most important that voltmeters, ohmmeters, powermeters, and ergmeters should be so constructed that the percentage increase of resistance of their fine wire coils due to the heating effects of the currents passing through them should be as small as possible, the question arises as to whether such coils should be made of German silver wire, or of copper, or partly of German silver and partly of copper wire, and how the diameter of the wire should vary in different parts of the coil. The authors have therefore been led to investigate the conditions that make this heating error a minimum with cylindrical coils of internal and external radii, r_0 and r_1.

At a place whose distance from the axis is r let the cross section of the wire be x_1, ρ the specific resistance of the material; then, assuming that

$$x = x_0 r^a, \quad \rho = \rho_0 r^b, \quad \rho x = \rho_0 x_0 r^c,$$

and that a current, c, in one spire of radius r produces a magnetic effect, KCr^d, on the suspended needle, they find that the heating error is proportional to

$$r_0 \rho_0 \frac{p^2}{(r_1^p - r_0^p)^2} \cdot \frac{n}{r_1^n - r_0^n} \cdot \frac{r_1^m - r_0^m}{m},$$

where $p = d - a + 1$, $n = 2 + b - 2a$, $m = 2 + 1{\cdot}144\, b - 4a$. The conditions that make this expression a minimum are worked out in the paper, the result being that with one of their magnifying spring solenoid instruments where $d = -1$, the values of a and b giving a minimum value are $a = 0{\cdot}325$ and $b = -0{\cdot}5$, and since in practice b cannot be negative they conclude that $b = 0$ and $a = {\cdot}4$ give the best results, *i.e.*, that all the wire employed in the bobbin should be of copper, and the law of increase of cross section proceeding from the centre should be $x = x_0 r^{0{\cdot}4}$. The actual waste of energy in the instruments is next considered, and lastly the authors show how to pass from a voltmeter with known winding, and whose maximum reading is P_1, to another of the same volume and shape whose maximum reading is to be P_2, and they conclude that as they have shown that the waste of energy is the same in both for their maximum readings, the resistances of the instruments must be proportional to the squares of P_1 and P_2, or following the law already arrived at for a minimum error due to heating, the cross sections of the wires of the two instruments at similar places must be inversely proportional to P_1 and P_2. The employment of outside coils for voltmetres is considered, and it is shown that if we desire the same error in the two instruments due to heating when the outside resistance coils are of the same size and shape, it is necessary to have the same ratio between the resistance of resistance coil and that of the magnetising coil in the two cases. To have a less or a greater error in the second case it is only necessary to have the equation

$$c\,(\text{the error}) = \frac{2 + F\,V}{1 + F\,V}.$$

where F is a constant and V the volume of the German silver resistance coil. From this V may be determined and the ratio $\frac{R_1}{R}$ of the resistances of the resistance coil and the magnetising coil is given by $\frac{R_1}{R} = \frac{F}{D}\,V$, where D is a constant which, like F, is obtained from experiments on the first instrument. The diminution of the heating error by using much iron in the instrument so as to obtain the same magnetic action with a much smaller current is discussed, and experiments were shown to illustrate how such employment of iron introduced a permanent magnetism error, and caused the indications of such an instrument on the lower part of the scale to be uncertain, and to depend upon whether measurements were being made with an increasing or a diminishing current.

"*On the Manner in which Light affects the Resistance of Selenium and Sulphur Cells.*" By Mr. Shelford Bidwell.—In a communication made to the society at its last meeting, the author had described a sulphur cell which behaved in all respects like a selenium cell when exposed to light. The action of this cell was supposed to be electrolytic, the sulphur containing a small quantity of sulphate of silver. If this were the case the result of the current traversing the cell would be to deposit sulphur upon the anode, and as sulphur has an enormous resistance, that of the cell would increase unless the sulphur thus deposited combined with the silver. It is this combination that is believed to be much facilitated by light, a supposition the author believed he had confirmed by direct experiment. Mr. Bidwell had also measured the resistance of a piece of selenium that was believed never to have been heated in contact with a metal. The specimen was crystallised by heating for some time in a glass mould, two opposite sides cleaned, and two pieces of tinfoil, between which the resistance was measured, pressed against them. In this way the specific resistance was found to be 2,500 megohms, which is enormously higher than that of the selenium in the "cells," a fact tending to confirm the theory that the conduction in such cells is due to the electrolysis of the selenides of the metals forming the terminals produced in the "cooking," and similar to that of the sulphur cell described above.

At another meeting of the society, Prof. Guthrie, President, in the chair, Dr. Ramsey, Messrs. T. Hands, F. W. Sanderson, W. A. Shenstone, and F. H. Nalder were elected members of the society. The following communications were read:—

"*On the Specific Refraction and Dispersion of the Alums.*" By Dr. J. H. Gladstone.—The refraction, dispersion, and specific gravity of nineteen different alums in the crystalling form were published by M. Charles Soret, of Geneva, in the *Comptes Rendus* for last November. These, together with some additional data from Soret, Topsöe, and Christianson, were employed by the author for comparison with certain experimental results of his own and of Kannonikof. In this way additional proof was obtained that a salt has the same specific refraction whether it be crystallised or dissolved, and that the refraction equivalent of a compound body is the sum of the refraction equivalents of its components. The refraction equivalents of the alkalies in these alums are in the following ascending order:—Sodium, potassium, ammonium, rubidium, methylamine, calsium, and thallium; and of the other metals, aluminium, chromium, and iron. This is in accordance with what was previously known, but Soret's observations do not afford the means of determining the equivalents more accurately than before. The refraction equivalents of indium and gallium were determined for the first time, giving respectively 17·4 and 14·8. The specific dispersion of the same compounds, measured by the difference between the specific refractions for the lines A and G, was also examined. The differences of dispersion are much greater comparatively than the differences of refraction. The order was also determined, but not the actual dispersion equivalents of the different elements.

"*On a Form of Standard Daniell Cell, and its Application for Measuring Large Currents.*" By Dr. J. A. Fleming.—The author first referred to the careful and thorough investigation of the circumstances affecting the electromotive force of Daniell's and allied cells by Dr. Alder Wright. He then described a form of all that had been found most convenient and reliable in practice. It consists of a U tube, in the two limbs of which are the two solutions of sulphate of copper and sulphate of zinc of the same specific gravity. Electrodes consisting of freshly electro-deposited copper and pure zinc that has been twice distilled dip into the two limbs. The E.M.F. of this cell is 1·102 and the variation of E.M.F. with temperature is practically *nil*.

"*On the Phenomenon of Molecular Radiation in Incandescent Lamps.*" By Dr. J. A. Fleming.—Some years ago Dr. Fleming had called attention to a phenomenon in incandescent lamps very analogous to that of discharge in high vacua observed by Mr. Crookes. The inner surface of the lamp-glass was sometimes found to be coated with a deposit of carbon, with the exception of a clear line marking the intersection of the glass with the plane of the loop, and being, in fact, a shadow of the loop apparently caused by an emission of matter from the terminals. Dr. Fleming has since found how to produce this appearance at pleasure by passing a very strong current momentarily through a lamp, and has succeeded in obtaining similar deposits of various metals that had been used as terminals. These deposits show colours by transmitted light, and as a general result the

author concludes that red metals, such as gold and copper, appear green by transmitted light, whereas white metals, like silver and platinum, appear brown, a conclusion which, however, was challenged by Captain Abney in the discussion ensuing.

"*On Problems in Networks of Conductors.*" By Dr. J. A. FLEMING.

"*Lecture Experiments on Colour Mixtures.*" By Captain ABNEY.—The apparatus employed by Captain Abney is a modification of Maxwell's colour box; the spectrum, instead of being formed upon a screen, is received upon a convex lens, which forms an image of the face of the prism upon a screen. If all the light from the prism falls upon the lens, this image is colourless, but by interposing a screen with a slit in the spectrum, close to the lens, so as only to allow light of a given colour to fall on the lens, the image appears coloured with that light. By using two or more slits different lights may be mixed in any required proportions.

"*On Stream-lines of Moving Vortex-rings.*" By Prof. O. J. LODGE.—The communication described a method of drawing vortex stream-lines consisting in superposing uniform motion represented by a series of parallel lines upon the lines of a stationary vortex as given by Sir W. Thomson in his memoir on vortex motion, and joining up the corners of the quadrangles so formed. This operation is very simple, and by its application a number of the more remarkable properties of vortex-rings may be obtained, the general analytical investigation of which involves mathematical methods of the highest order. Drawings were exhibited showing the nature and behaviour of a single votex-ring moving with different velocities, a vortex-ring approaching a large distant obstacle, the chase of two unequal rings, and many other cases.

"*On the Thermo-electric Position of Carbon.*" By Mr. J. BUCHANAN.—It having been observed that the carbon filaments of incandescent lamps usually gave way at the negative end, experiments were instituted to find if the destruction could be due to the "Peltier effect" causing a local generation of heat. Observations on a platinum carbon thermo-couple showed that a generation of heat would result from a current passing from carbon to platinum, but the effect was too small to account for the observed phenomenon. It was found that a couple of carbon iron rose considerably in E.M.F. by maintaining the hot joint for some time at 250° C.

"*On Some Further Experiments With Sulphur Cells.*" By Mr. SHELFORD BIDWELL.—The paper contains (1) a description of a class of cells which give a constant voltaic current, the electrolyte consisting of a solid metallic sulphide; (2) an explanation of the unilateral conductivity exhibited by selenium and by sulphur cells; and (3) a description of a cell which gives, as the result of passing current through it, a current in the same direction as the primary current.

THE PHILADELPHIA EXHIBITION, 1884.*

(Continued from page 106.)

REPORT OF EXAMINERS.—*Section VI.—Carbons.*

In addition to the experiments mentioned in our last, two other experiments were made, as follows: The pencil was broken up in the mortar and the finest particles separated by the sieve; the coarser grains were weighed, thrown into distilled water and boiled. The water was then cooled down to 60° F., the granules transferred to the specific gravity bottle and a new determination made. In both cases the specific gravity was much higher than that of the finely powdered portion of the same sample, as will be seen from Table II.

This would seem to indicate that some volatile gas was driven off during the process of boiling. A further observation was made, viz., that the material composing the pencils is not of uniform density. When the sample is finely powdered, thrown into water and stirred with a glass rod, a portion sinks, but another portion (somewhat like an oily scum) floats upon the surface. This is doubtless some pitch or tar compound used to cement the materials together. Most of the carbons used in actual practice are coated with a superficial layer of copper, and as this would render specific gravity determinations of no value, the plain carbons only were used, with the exception of one sample exhibited by the Buffalo Company, covered with a coating of borate of lead. There was also a carbon pencil examined having the peculiarity of a central core (resembling graphite) a little larger in diameter than the core of an ordinary lead pencil. It was noticed when these different determinations were tabulated that the specific gravity of the powdered carbon was (as might be expected) in each case greater than that of the pencil, and furthermore that the pencils showing the highest specific gravities were not made from the densest materials. Considerable difference was also noticed in the hardness of the different samples.

The figures given in Table II. are the average of two weighings of the same sample after drying.

The following table shows the specific gravity of the two coarsely powdered samples which were boiled in distilled water:

Brush carbon.....	2 grammes taken	sp. gr., 1·908
Carré	do.	sp. gr., 1·982

5. *Microscopical Examination of Thin Transverse Sections of the Carbons.* This was made by Dr. Persifor Frazer and yielded the following very interesting results. The examination of the five thin sections of the electric light carbons submitted was undertaken with an 8-10 Zentmayer lens and a Beck parabolic reflector. The sections were in fair order (with the exception of some dirt on the inner surfaces of the cover glasses) except that No. 5 was broken across the cover glass, and the latter as well as the carbon section detached from the slide.

No. 1 was taken from a Brush carbon, No. 2 was taken from a Wallace carbon, No. 3 was taken from a Boulton carbon, No. 4 was taken from the Buffalo Company's carbon, No. 5 was taken from the Carré carbon.

The preliminary examination was made without a reflecting mirror, and with a low eye-piece, giving a magnifying power of about 50 diameters.

No. 1. Under these circumstances No. 1 presented an opaque surface, except in a few spots where the film was torn away, and a few translucent particles. The colour of its surface was silver grey, with foliated masses of carbon of decidedly graphitic appearance distributed through the field. Under the reflected light of the parabolic mirror the substance of the section, though of coarser structure than appeared in the other slides, seemed of considerable constancy of composition. The largest grains were about 0·1 mm., and the smallest 0·03 mm., the latter measurement quite accurately representing the size of the pores. All the bright spots are surfaces showing high metallic lustre and grey colour, with lines of striation and fracture.

No. 2. Without the reflector No. 2 presented the appearance of a fine-grained surface covered with small rounded nodules or minute botryoidal masses, and showed little if any traces of foliation or crystallisation. Under reflected light (and exposed on the underside to a parallel beam) the largest opaque grains were 0·03mm. and the smallest 0·015mm. The average size of the opaque grains was 0·02mm. These are, in a rough estimate, from 1 to 2 per cent. of visible foreign matter in the carbon in the form of grains of various substances (which are generally translucent) in the carbon. Some of these reach a size of 0·1. There are fewer pores in this than in No. 1, but those which exist are larger. The largest part of the substance is very fine-grained, but large dark grey angular discs are very generally distributed throughout the mass. In the photograph these dark grey flat bodies are visible, and the constituent parts of the fine mass are less sharply defined and separated. But, in fact, the photograph cannot give either the colour or the lustre of the original, and is mainly useful in giving an idea of the texture of the surface.

No. 3. Without the reflecting mirror No. 3 showed an extremely fine-grained texture, with comparatively few and quite small points of silver-gray colour and metalloid lustre. Under the mirror the grains measured from 0·05 to 0·02. The texture was extremely fine-grained and compact, and the structure exceedingly homogeneous. The colour of the surface was a lighter grey than that of any of the other slides, and was tinged yellowish in irregular blotches, which may however have been the result of the accidental addition of a foreign body in mounting. Occasional translucent oblong particles were seen measuring 9·1 mm. to 0·05 mm. along their longer sides. The surface exhibits small and large masses of slightly greenish colour attached to each other, and nowhere separable into distinct grains. The smallest of these constituent parts are not so small as those of the matrix of No. 2; and the largest not as large as the dark angular fragments in the same slide. The structure is nowhere compact, but loose and spongy. There are visible a few small striated particles of irregular outline.

No. 4. Without the mirror the texture appears very fine, but little granular in character. The very small points of steel-grey colour of graphitic aspect are less numerous than in 2 and 3. With the reflector the grains varied in size from 0·01mm. to 0·03mm., the average being rather nearer to the first measurement. The colour was a somewhat darker grey than that of No. 3, and the number of very minute particles

* From the *Journal* of the Franklin Institute.

Digitized by Google

of foreign matter was greater; most of these were translucent, and measured about 0·02mm.

No. 5. Examined simultaneously in reflected and transmitted light. No. 5. shows a very large number of holes, which have doubtless been caused by the more ready crumbling of certain of its constituent grains. Those of the latter which are opaque measure from 0·02mm. to 0·01mm. The grains are not so fine as in the last specimen, and the structure seems to be less homogeneous. From the existence of numerous very fine points of various colours in transmitted light, and the existence of the holes formerly mentioned, it would seem that the powdered carbon has been mixed with very fine sand or earth, either accidentally or purposely, before having been moulded into sticks. The ground mass has a fine grained, dark greenish appearance, of the same character as that of 3 and 4, *i.e.*, resembling a surface of a decomposing mineral. A number of dark grey, flat, angular objects are scattered through the mass as in No. 2.

Resistances of Arc Light Carbons.—The following measurements of resistances of electric light carbons were made at Cornell University last winter. The carbons were selected at random from those which Prof. Sadtler procured for tests, and probably represent a fair average. The method pursued in measuring the resistances was as follows:—The carbon to be tested was connected in circuit with a piece of very uniform German silver wire, a known length of which measured 1-10th ohm. To connect the carbon in the circuit, a hole, which the carbon fitted tightly, was bored in the side of a wooden block, and a second hole bored from the top of the block to meet the first. Such a block was fitted upon each end of the carbon and the vertical holes filled with mercury. Into this the connecting wires were placed. The resistance of the carbon was determined by obtaining, upon the German silver wire, points having the same difference of potential as points on the carbon near the two ends. Measuring the distance between these points on the German silver wire, and comparing with the known length for 1-10th ohm, gave the resistance of the carbon. To determine the points of equal difference of potential, a Thomson galvanometer of 10,000 ohms resistance, differentially wound, was used. The coils were adjusted so that no deflection occurred when the same current flowed in opposite directions through them. Their resistances were also adjusted to exact equality. The terminals of one pair of coils were then connected with points near the ends of the carbon, and the terminals of the other pair with sliding contacts on the German silver wire. The method of using the instrument will now be evident. It was far more sensitive than was necessary for the purpose, but could nevertheless be used with great facility. The measurements were made by Mr. E. T. Turner, a young man doing some post-graduate work in my laboratory. The results are given in Table III.

* This was a hollow carbon having a core of some different material. To make sure that the high resistance was not a mistake, it was measured also in the ordinary way by the bridge, with the same results.

SIXPENNY TELEGRAMS.

In the House of Commons on Tuesday last Dr. CAMERON asked the Postmaster-General whether he could inform the House how much of the £500,000 estimated as required to prepare for the proposed introduction of sixpenny telegrams on the 1st of August had yet been expended; and whether he proposed to proceed with the Postal Telegraphs Bill with or without provision for free addresses, as proposed in the amendment to the Bill of which he recently gave notice.

Lord J. MANNERS: With reference to the first part of the question, I have to say that the whole sum of £500,000 will be spent in making the necessary arrangements. With respect to the second part of the question, I would remind the hon. member that the Chancellor of the Exchequer laid down on Monday night the lines which the Government would wish to follow with reference to legislation. My right hon. friend said that it was the desire of the Government not to proceed further with legislation of a contentious character. Now, the object of the Bill to which the latter part of the question refers is to abolish free addresses on telegrams, and that is a question which has been very much contested in the House and outside. I think, therefore, that the Government will not be disposed to proceed further with this Bill during the present session. A fact bearing upon the finance of this question has recently been brought to my notice. It has been calculated by the officers of the department that if the estimate of the contemplated increase of business mentioned by my predecessor in office were realised, there would be an additional outlay required in the course of about four years amounting probably to not less than £1,000,000. This outlay would be necessitated by the erection of underground wires from London to the principal towns of the kingdom. I may also say that the scheme proposed by this Bill could not under any circumstances be brought into operation before October. Therefore, weighing all these considerations together, the Government are of opinion that it would be inexpedient to proceed further with this measure this session, and that it would be wise to remit the whole question to the next Parliament.

Mr. SHAW-LEFEVRE asked whether the Government would give the House an opportunity of discussing the subject. If no such opportunity were given, great dissatisfaction would be felt.

Mr. PULESTON wished to know whether the calculation to which the Postmaster-General had alluded was a new one.

Lord J. MANNERS said it was an estimate which he found in his office, and of which he had not heard previously.

Mr. SHAW-LEFEVRE said he had no knowledge of any such estimate.

Lord J. MANNERS: I have given the facts as they have been given to me in the office.

During the course of the further business of the House, Mr. SHAW-LEFEVRE desired to add a few words on the subject of the Telegraphs Bill. From what had fallen from the noble lord that evening he had gathered that it was the intention of the Government to drop that measure. The announcement that the Government did intend to drop that measure would cause surprise and regret throughout the country. For many months past the expectation had been held out that a considerable change would be effected in the telegraph rate during the late autumn, and he desired to bring under the attention of the Government the financial effects of dropping that measure. He could not help thinking that the Government had not sufficiently considered the fact that £500,000 had been spent upon new plant which would be necessary in case the cost of telegrams was lowered from 1s. to 6d. Moreover, a very large staff had been taken on at the Post Office with a view of introducing the new tariff during the coming autumn. Twelve hundred persons had been taken into the service of the Post Office within the last few months in view of the reduction of the tariff and the increased work which that would throw on the department, and their salaries would amount to £61,000 per annum. Those persons, who were now learning their business, could not be utilised in any other way in the Post Office, and as they could not be dismissed the money expended upon their salaries would be altogether thrown away. The noble lord had given two reasons for abandoning the Bill. In the first place he had misdescribed the Bill, because he had said it was a Bill for charging the addresses. That was a misdescription of the measure, which was a Bill for altering the tariff and for enabling a short telegram to be sent for sixpence instead of for a shilling. In order to confer this very great boon of sixpenny telegrams upon the public it had been found necessary not to allow the addresses to be free. If free addresses were allowed it would involve a very great loss to the revenue, which, taken together with the reduction of price, would amount to some £200,000 per annum. Among the other reasons which the noble lord had given for abandoning the proposals contained in the Bill was that he had received information from the department that if the change was carried out in the manner proposed by the Bill the increase of business which would result from it would occasion an expense of an additional million to the country in the course of the next three or four years. For his own part he thought there must be a misunderstanding on this point, as he had received no information from the department to that effect. He was under the full impression in consequence of the information which he had received from the department, that the half million of money which had been asked for during the current year would amply suffice for purchasing the plant rendered necessary by the anticipated increase of business which would be caused by the reduction of the tariff. It had been calculated that that increase of business would amount to about 30 per cent. on the present business, and he believed that the new plant which had been provided would be amply sufficient to meet that increase in the amount of business. Should there, however, be in successive years a still greater increase of business than that now anticipated there would also be a corresponding increase in the profits of the department, which would amply suffice to meet any additional charge for plant that might be rendered necessary by the increased business. If

Digitized by Google

the Bill were to be now dropped all the expenditure which had already been incurred during the present year would be lost to the country. He suggested that the noble lord should proceed with the Bill, and introduce in committee any alternative tariff which he might desire to propose, but he must say that he did not believe that within the financial limits which would be sanctioned by the Treasury the noble lord could propose any other tariff than that set forth in the Bill. Should, however, the noble lord think fit to propose any alternative tariff he could promise him that it should receive his most favourable consideration. He was satisfied that there was a general desire on the part of the House that the Bill should become law, and that the reduction in the tariff to sixpence should be made as soon as possible. He thought it would be desirable that the Government should give one day to discuss the Bill in committee. He rather thought, however, that now the noble lord was responsible for the department, and had an opportunity of discussing the matter with the very able officers at its head, he had discovered that it would be impossible to comply with the rule that the telegraphic department should be a paying one and at the same time to propose any alternative tariff. There was only one other argument—namely, that in the general election it would be a great boon if this reduced tariff should be brought into effect. There would then be a good opportunity of testing it, and he believed the system would be enormously availed of.

Lord J. MANNERS said he wished to remove an erroneous impression from the mind of the right hon. gentleman. He had no intention whatever of removing the Bill from the orders. He proposed to let it remain on the order for the right hon. gentleman to avail himself of if necessary.

Mr. SHAW-LEFEVRE asked would the noble lord give him an opportunity of proceeding with the Bill.

Lord J. MANNERS said he should do all he could to give the right hon. gentleman that opportunity. In the short time that remained, if he could not formulate an alternative scheme, and if he did not satisfy himself or the Treasury, then he would fall back on the scheme of the right hon. gentleman and see what could be done. He wished to point out that he had confined his amendment to free addresses. He had said that whatever was suggested the addresses should be free. He was still of that opinion, and that the abrogation of free addresses would be a very serious loss and inconvenience. The right hon. gentleman had again spoken of the introduction of sixpenny telegrams. But the Bill would do nothing of the kind. It would introduce an eightpenny, a ninepenny, or a tenpenny telegram. No doubt that would be a very good and useful diminution, but he protested against it being spoken of as a Sixpenny Telegram Bill. As to the outlay the right hon. gentleman was aware that it was not the practice in the office to prepare estimates for three or four years in advance. When he came to inquire into the question on the basis of the increased business which the right hon. gentleman himself anticipated, he found that it was calculated that at the end of three or four years an outlay of about a million for underground wires and other matter would have to be incurred. That was the statement he had before him, and it came upon him with great surprise, but he never supposed or suggested that the right hon. gentleman was in possession of those figures when he made his statement to the House. He thought it well, however, when the question arose as to proceeding with the Bill in the present Parliament to state the facts to the House.

COMPANIES' REPORTS.

The Eastern Telegraph Company (Limited).

Report and accounts of the Directors for the half year ended 31st March last to be presented to the twenty-sixth half-yearly ordinary general meeting at Cannon-street Hotel on the 16th inst. at one o'clock:—

The revenue for the period amounted to £371,682. 19s. 11d., from which are deducted £91,599. 14s. 2d. for the ordinary expenses, and £44,815. 4s. 7d. for expenditure relating to repairs and renewals of cables, &c., during the half year. After providing £2,775. 16s. 2d. for income-tax, there remains a balance of £232,492. 5s., to which is added £30,364. 5s. 6d. brought from the preceding half year, making a total available balance of £262,856. 10s. 6d. From this balance there has been paid—

Interest on debentures and debenture stock	£27,370	13	9
Dividend on preference shares	20,384	13	7
An interim dividend of 1¼ per cent. on the ordinary shares	47,500	0	0
	£95,255	7	4

Leaving a balance of £167,601. 3s. 2d., from which £100,000 has been carried to general reserve. The Directors now recommend the declaration of a final dividend for the year ended 31st March, 1885, of 2s. 6d. per share, and a bonus of 1s. per share, amounting to £66,500, both payable on the 16th inst., making, with the three previous payments on account, a total distribution of 12s. per share, or 6 per cent. for the year on the ordinary shares. The balance of £1,101. 3s. 2d. shown at the foot of the revenue account is proposed to be carried forward to the next half year. The revenue includes £11,700 dividend for the half year upon the Company's shares in the Eastern and South African Telegraph Company. Also £2,600 net receipts for the same period on the shares of the Black Sea Telegraph Company belonging to this Company. The Directors of the Eastern and South African Telegraph Company have resolved to duplicate their cable between Zanzibar and Mozambique. This section has been interrupted during the spring months of each year since the cable was laid, causing loss of traffic to the companies, and great inconvenience to the Imperial and Colonial Governments and the mercantile community. The duplication will be charged to the reserved fund of that Company. An arrangement has been entered into by the Company with the Turkish and Greek Governments for the laying of a duplicate cable between Syra and the Island of Chios, 100 miles. The several sections of the Company's cables, and the land lines in connection therewith, are in good working order, with the exception of the 1870 Aden-Bombay cable, which is now under repair. The Company's two cables between Aden and Bombay were both interrupted on the 3rd June. One of the cables was repaired on the 27th June, and the communication by the other line can be restored with one or two calm days. The joint purse agreement with the Indo-European Telegraph Company prevented any serious loss of revenue. The steamship "Electra," referred to in the last report, has proved a valuable addition to the Company's list of repairing ships, having already effected four important repairs. The cost of the ship has been charged to the capital account. To meet the further requirements of the service it has been found necessary to build another steam ship, larger than the "Electra," with twin screws, and the Directors have entrusted the work to Messrs. R. Napier and Sons, the builders of the "Electra." The Directors have purchased on satisfactory terms the buildings at Alexandria and Port Said, previously rented by the Company, as offices and quarters for the staff.

Business Notice.—Mr. H. Thorpe has transferred his manufacturing premises to 34, Eagle-street, Red Lion-square, W.C. The offices and warehouse continue to be at 59, Theobald's-road, London, W.C.

THE INTERNATIONAL INVENTIONS EXHIBITION.

We have mentioned in previous articles that for the first time on this side the water the opportunity is given at the Inventories of studying the Thomson-Houston system of lighting. At the late Exhibition of the Franklin Institute at Philadelphia this system attracted attention, and has since come even into greater prominence in the States. This part of our review of the Inventories being merely descriptive we make no attempt at comparison, but we may venture so far to say that this exhibit has "performed successfully." Whether the machine is more efficient electrically, or more simply constructed mechanically, are questions to be considered elsewhere; suffice it for the present that the light from the lamps is steady and good, and the machine seems to do its work well. The reputation gained by the Thomson-Houston system in the States proved an incentive to business men in England, and several opened negotiations with the American company to take up the agency in England. Perhaps we are divulging no secret when we say that instead of writing letters and waiting replies, Mr. Wharton, of Laing, Wharton, and Down, took the business-like plan of telegraphing across the Atlantic that he had started to negotiate in person. He went across to America, and gained his object, coming back as agent for the Thomson-Houston system. The exhibit, therefore, at the Inventions Exhibition is under the control of Messrs. Laing, Wharton, and Down. It consists of one 45-light 2,000 candle-power dynamo machine, running 38—40 lamps in the East Gallery, and the balance about the gardens at each end of that gallery; one 18-light 1,200 candle-power dynamo machine lighting the East Arcade and the East Annexe; one 6-light 4,000 candle-power dynamo machine, lighting gardens. The two latter machines are running a high-speed Armington and Sims' engine. The 45-light machine is also running on the stall in the East Arcade eighteen incandescent lamps of 8 candle-power each by means of a special distributing arrangement, and two lamps each of 1,000 candle-power.

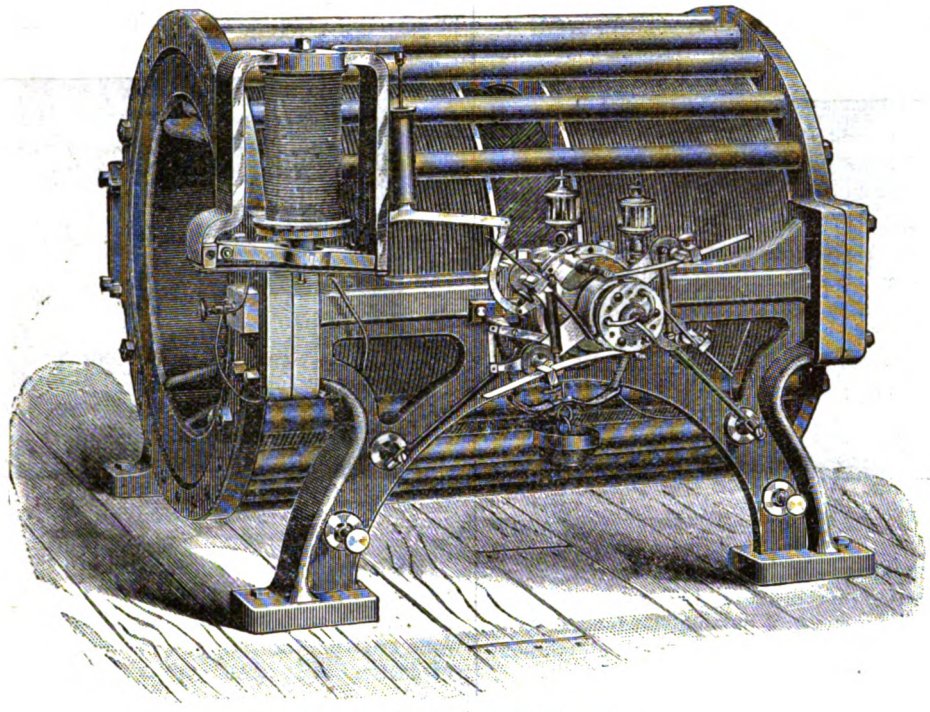

Fig. 1.—Thomson-Houston Dynamo.

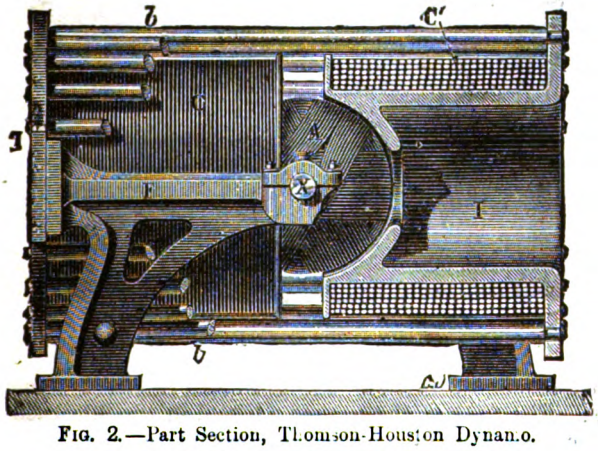

Fig. 2.—Part Section, Thomson-Houston Dynamo.

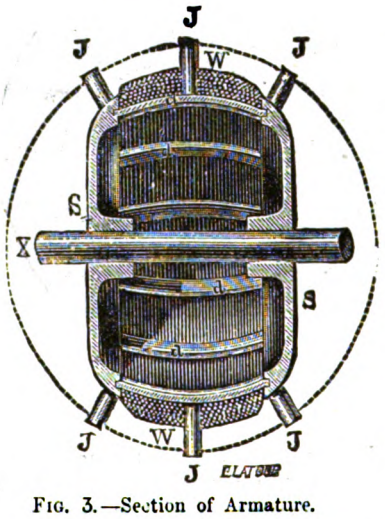

Fig. 3.—Section of Armature.

Before describing the machine, it may be well to give a list of the merits claimed for it by the company, although it seems to us that in the majority of cases these so-called merits are possessed in common—or rather, we should say, claimed in common—by almost all dynamos. The merits set forth are as follows:—1. Extreme simplicity, there being only three coils of wire on the revolving portion, or armature, and three pieces of copper in the commutator. 2. The complete enclosure of the armature by the coils and magnets of the machine, concentrating the power where it should be applied to produce

Digitized by Google

the best results, and preventing injury to the moving parts, or danger to the machine from iron objects being drawn into it. 3. The highest efficiency, due to the enclosure of all the wire of the armature where the electricity is generated, by a most powerful magnetic field, giving great saving in horse-power to produce a given result. 4. The spherical form and small size of the revolving portion or armature, giving the least possible air resistance or loss of power by fanning air. 5. The form and size of the armature, preventing the possibility of injury due to centrifugal force. 6. The compact and encased condition of the parts, such as insulated wire, rendering them not subject to injury by contact with surrounding objects. 7. The continuous character of the current and its consequent advantages. 8. The machine

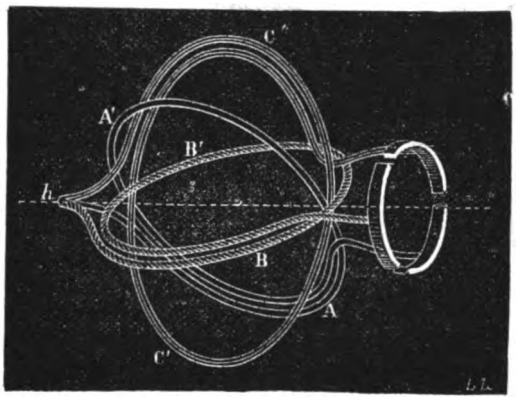

FIG. 4.—Winding of Coils of Armature.

possesses the simplest commutator in the world, giving continuous currents; and from its construction there is no danger of injury to its insulation, so often the cause of putting the generators of other systems out of service. With the air-blast attachment oil may be freely used on the commutator, and the wear of its segments and of the brushes then amounts to almost nothing. 9. The generator requires less attention to keep in order than any other, and with the automatic regulator attached its power is adapted to the number of lights it is desired to maintain. 10. There is little noise or hum produced during

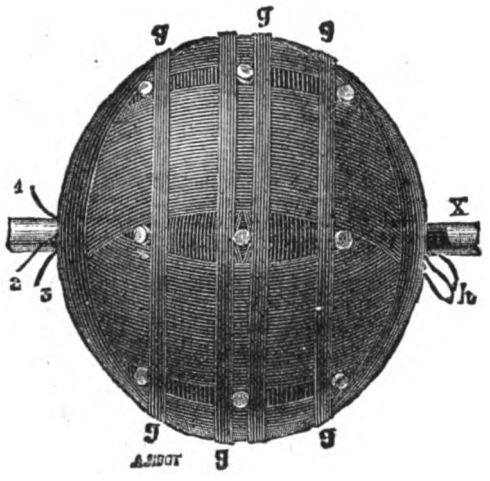

FIG. 5.—Complete Armature.

running, so often an objectionable feature of other generators. 11. The wearing in the boxes is reduced to a minimum by the lightness and balance of the revolving parts. 12. The thoroughness of insulation of all its parts, where needed. 13. The replaceability and interchangeability of its important parts. 14. The freedom from risk of short circuits, the potentials being so distributed as to secure this result.

The Thomson-Houston dynamo differs considerably in external appearance from most other dynamos. It embodies the joint work of Elihu Thomson and Edwin J. Houston. Fig. 1 shows the external view of the machine, while Fig. 2 shows some parts in section. We may say here that we are indebted for these illustrations to the courtesy of the American Company and Messrs. Laing, Wharton, and Down. A frame, F F, carries the bearings for the shaft of the armature, and also supports the field magnets, which consist of two hollow cylinders. The inner end or pole piece of each cylinder is hollowed out spherically, having a central opening, so that when the two are placed in position they enclose a spherical space, in which the armature revolves. At their outer ends the cylinders are flanged, and form the annular plates, as shown. These plates are connected by the iron bars *b b*, shown in Figs. 1 and 2. It will easily be seen that these soft iron bars form the central portion of the magnet core; at the same time they act as a protection to the wire C of the field magnets.

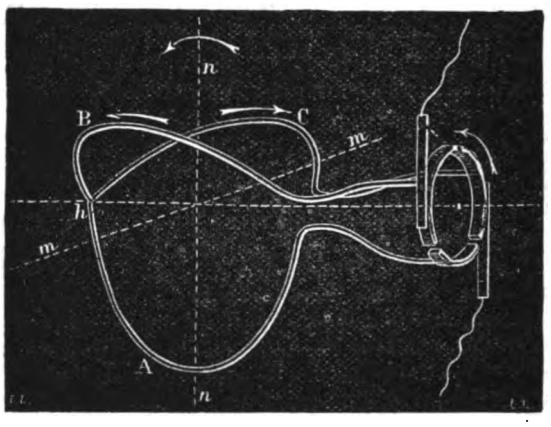

FIG. 6.—Direction of Currents.

Coming now to the armature, which occupies the spherical space before mentioned between the poles of the field magnets, it will be found to consist of three coils of wire wound around an iron core, resembling in form an ellipsoid of revolution. The iron core is built of two concave plates, *s s*, as shown in Fig. 3, keyed to the shaft. The edges of the plates are bridged over by the light iron pieces *d d*. There are generally 12 of these cross pieces, whose ends are carried in circular grooves in the rim of the iron plates. On these bridge pieces are wound a quantity of well annealed soft iron wire, W W, varnished to insulate the various machines. The wire used varies with the design of the machine. Wooden pieces, J J J, are inserted in the

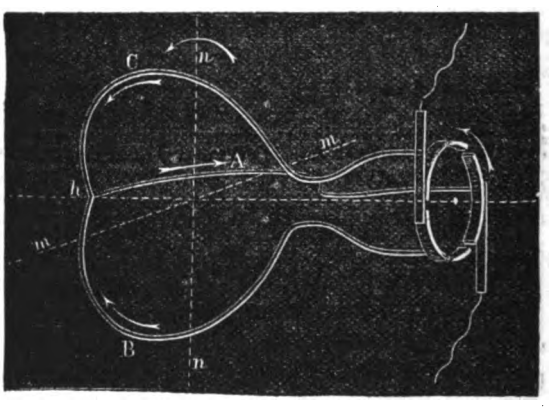

FIG. 7.—Direction of Currents.

edges of the plates S S acting as guides for winding the coils. Fig. 4 shows the method adopted in winding each coil. The coils, three in number, are wound at angles at 120° relatively to one another, as will be seen from the figure. It will be noticed that the three entering wires are joined together at *h*, while the three outgoing wires have their ends joined to the three equal segments of the commutator.

When the armature, shown complete in Fig. 5, is to be wound, the core is first covered with thick paper, which is made to adhere by a varnish of gum lac. Then, commencing at *h*, one-half of the first coil is wound; the core is then turned 120° and one-half of the second coil is wound. The third coil is also commenced at *h*, but is wound full length.

Digitized by Google

Then the second half of the second coil, and finally that of the first coil are completed, over the surfaces corresponding to their first halves. The inner ends of the wires are connected at *h*, as stated above, and the external ends are carried to the sections of the commutator, the points at which the various coils cross each other being covered with insulating material. It will also be noticed that the crossing of the coils increases the thickness at certain points, so that the final shape of the

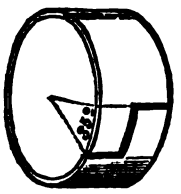

FIG. 8.—Old Form Commutator.

armature more nearly resembles that of a sphere than that of the original core. By the method adopted it is claimed that the highest differences of electric potentials are found only upon the outside wires, and that the conditions are very favourable to the retention of insulation under varying circumstances. The action of the machine may be described by reference to Fig. 4, which shows the armature in skeleton. It will be noticed that the two opposite portions, A A, of the same coils, passing at the same instant before opposite poles, generate currents which combine, consequently the three coils may be considered as reduced to their three halves A, B, C. These are represented in Fig. 6 by three semicircles at angles of 120° from one another, the ends connected at *h* and to the commutator, as shown.

The brushes are placed diametrically opposite to each other and parallel to the line of maximum effect. By referring to Fig. 6 it will be seen that in such a position, A being situated in the neutral line, its corresponding segment will not be touched by the brushes and it will consequently be cut out of the circuit. At the same time B and C pass under opposite

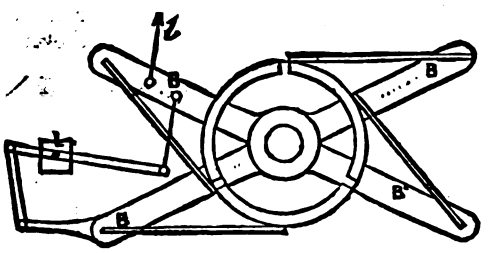

FIG. 12.—Brush Holder.

poles, communicate their current to the brushes, and are connected in series. When, on the contrary, A coincides with the maximum line, as shown in Fig. 7, B and C will pass under the same pole and one of the brushes will simultaneously touch the adjacent ends of their respective commutator segments. At this point B and C will momentarily be joined in parallel or quantity, and together they will be in series with A. An instant later (the armature turning in the direction of the arrow), B will be cut out of the circuit, and A and C united in series, which action is constantly repeated.

It will be noted that each coil is cut out of circuit the moment it traverses the region of smallest effect, but by means of the simple arrangement shown the cutting out of circuit of each coil takes place at the instant the latter reaches a point 60° from the neutral line; or, in other words, when it has reached a point at which it is no longer important to collect its current.

Prof. Thomson accomplished this at first by cutting the segments of his commutator so as to leave steps at the ends (Fig. 8), which lap over about 35°. In this way two adjacent coils, B and C for example (Fig. 7), remain in parallel while the armature passes over an arc of 35°, and the currents generated in B during that time are utilised. Another advantage of this arrangement consists in the fact that each brush comes in contact with a coil at the moment in which the latter becomes active, and does not leave it until it is almost completely inactive. The spark due to the extra current is consequently considerably diminished.

This form of commutator, although efficient, has been replaced by another, in which the segments terminate as usual in simple square ends. The same result is accomplished, however, by substituting two brushes instead of one. Both brushes of each pair are connected together, but the respective brushes are placed so as to touch the commutator at points 35° from each other, which arrangement is obviously equivalent to the first. Fig. 9 shows this in a very clear manner, the coils being

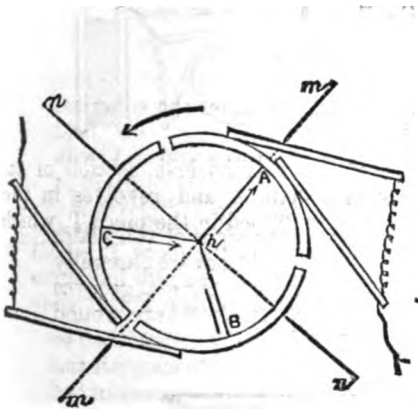

FIG. 9.

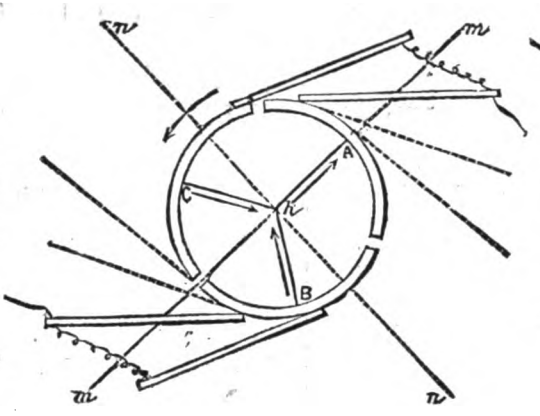

FIG. 10.

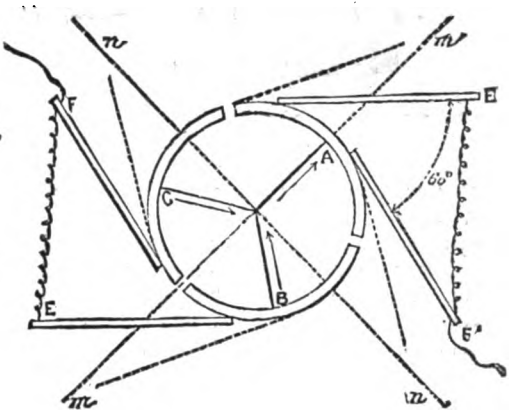

FIG. 11.

represented by three straight lines, intersecting the commutator segments. This figure also shows the neutral and maximum lines in their true position, designated respectively by *n n* and *m m*. In the position shown, it is easy to see that the arrangement maintains the coil B in circuit up to the point where it reaches the neutral line.

Prof. Thomson regulates the current of his machine by varying the position of the brushes with respect to the commutator, and he accomplishes this object in two ways.

The first method, which he terms *forward regulation*, is employed when a diminution of current is required, and consists simply in advancing the position of the brushes a certain distance on the commutator. By referring to Fig. 10 it will be seen that by this means the contact of each coil with the brushes is maintained even after it has passed the neutral line some distance. As the current generated in the coil after passing the neutral line is in an opposite direction, it follows that, being still in connection with the same brush, it will generate a counter electromotive force which will tend to diminish the total current. The second method mentioned is termed *backward regulation*, and is now generally used. Under normal conditions, the brushes in each pair form an angle of 60° between them, and touch the commutator at points also 60° apart, as shown in Fig. 11; consequently the angular distance between the first of one pair and the second of the other pair of brushes is 120°, *i.e.*, the length of one segment of the commutator. It is evident that with this arrangement none of the coils will be cut out of the circuit, since each segment of the commutator will have to pass from one pair of brushes to the other at the instant the coil itself is at the

Digitized by Google

neutral line; thus there are always two coils in parallel, joined in series with a third.

When the machine is working normally the position of the brushes is that just shown; but when a reduction of the resistance in the external circuit necessitates a reduction of potential it is accomplished by a peculiar movement of the brushes. In order to accomplish the desired result the brushes F F' are given a retrograde motion, while at the same time the brushes E E' (Fig. 11) advance a distance three times as great as the former recede, as shown by the dotted lines.

The device employed for the purpose of effecting the differential movement of the brushes is shown in Fig. 12. The brush-holders B B are connected to those of B' B' by the lever L vibrating on a pivot so placed that the relative lengths of the lever arms are as 3 to 1.

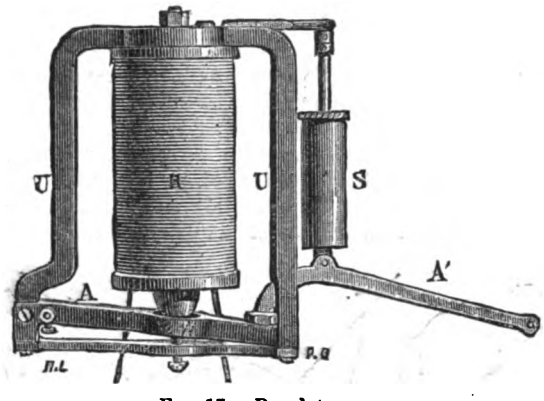

FIG. 13.—Regulator.

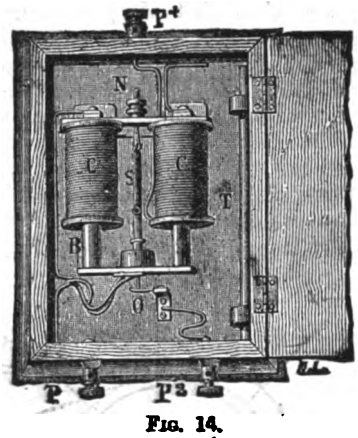

FIG. 14.

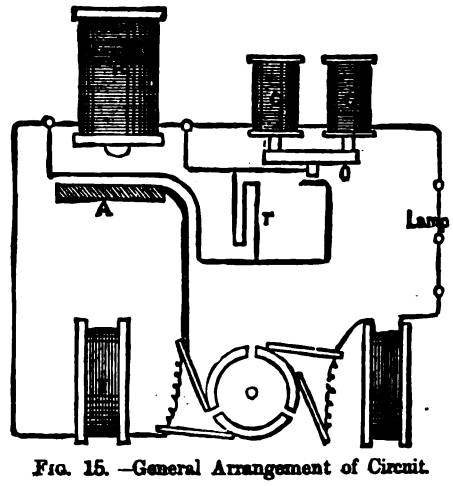

FIG. 15.—General Arrangement of Circuit.

This system of brushes is operated by a regulator-magnet, supported at one side on the frame of the machine as shown in Fig. 1. The regulator is shown in detail in Fig. 13, and consists of a U-shaped standard, U U, carrying the armature A at its lower end. The end of the core of the electro-magnet is in the shape of a parabola, and enters a corresponding cavity in the armature. The proportions are such that the attraction is constant for a given current in every position of the armature within the limits of its movement. The armature has a prolongation A' which transmits its motion to the brush holders by means of the rod *l* (Fig. 12). The dash pot S prevents any violent motion of the lever A'.

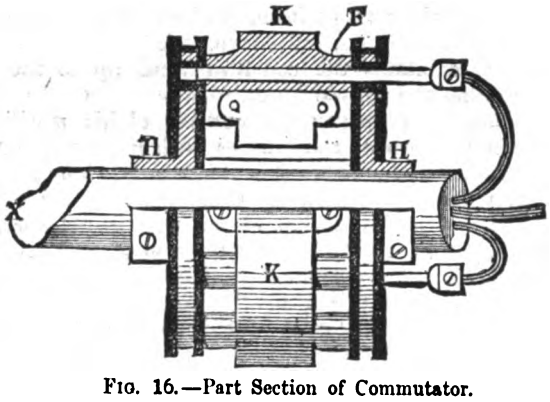

FIG. 16.—Part Section of Commutator.

If the main current were allowed to pass directly through the magnet R it would act as a regulator, but its action as such, would not be sensitive enough. For this reason the current is, in addition, passed through a pair of helices, C C (Fig. 14), the cores of which are suspended by a spring, S. When the current is of normal strength the cores rest upon a finger at O, which contact completes a shunt of no resistance around the electro-magnet R, and the latter consequently remains inoperative. If the current becomes too strong, however, the helices draw their cores upward and break the contact at O, which sends the current through R, and causes A to move the brushes accordingly. In order to prevent sparking at O, a carbon resistance, T, is shunted around it, as Fig. 15, which shows the arrangement of the entire circuit.

Prof. Thomson has introduced into his machine an ingenious device for the purpose of preventing the formation of such arc. He has found that in order to accomplish this a thin blast of air directed against the commutator suffices, and that it possesses the additional advantage of permitting the commutator to be freely oiled. Fig. 16 shows the commutator partly in section, while Fig. 17 illustrates the method of applying the air jets, the two nozzles B^3 B^3 being placed opposite to the ends of each forward brush. In the normal position of the brushes a small spark is produced at the ends of the commutator segments, against which the air blast is directed, preventing any injurious action on the former. The blower which furnishes the puffs of air is illustrated in detail in Fig. 18, which shows a transverse section of it. The hub D is mounted on the shaft X and revolves in the centre of an elliptical chamber contained in the piece T, which is supported by the frame of the machine. The hub has three radial slots in which the wings of hard rubber P P P slide

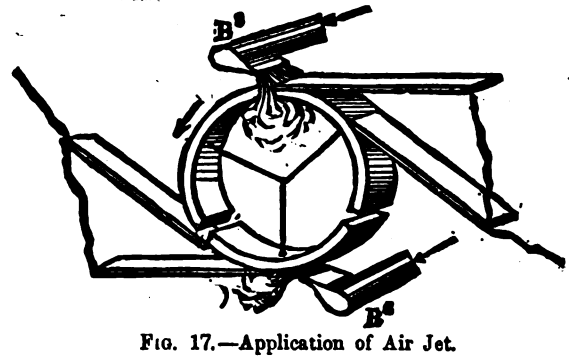

FIG. 17.—Application of Air Jet.

freely. During the rapid revolution of the axis the wings are kept against the sides of the oblong chamber and push the air before them, acting in the same manner as a rotary air-blower. O O are the air inlets and Z Z are the outlets, which

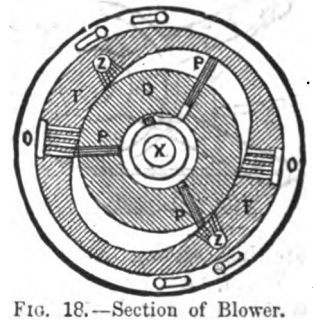

FIG. 18.—Section of Blower.

are connected to the nozzles above the commutator. The inlets are covered with wire gauze to prevent the entrance of dust particles, and the hub D is fixed on the shaft in such a position that the jet of air shall be strongest at the moment in which the edges of the commutator pass under the brushes.

NOTES.

UNDERGROUND WIRES IN CHICAGO.—The work of placing the electric light, telegraph, and telephone wires underground in Chicago has begun in real earnest.

VENTILATION AND ELECTRICITY.—The restaurant Marguery, in the Boulevard Bonne-Nouvelle, in Paris, is about to be fitted up with 4 *punkahs*, put in motion by a Gramme motor.

PERSONAL.—We understand that Mr. Alexander Bernstein has taken up his residence in England in order to personally manage the newly-organised Bernstein Electric Lamp Company.

NOMINATION.—We are glad to hear that the distinction of the Légion d'Honneur has been conferred upon M. Lazare Weiller, the inventor of the now well-known bronze-silicium wires.

THE ELECTRIC LIGHTING ACT.—On Monday Baron Henry de Worms informed Mr. Warton that the Government had no present intention of proposing any amendment of the Electric Lighting Act, 1882.

LIGHTING OF A LARGE STEAMER.—The contract for electric lighting the large steamship "Algoma," recently launched by Messrs. J. L. Thompson and Sons, has been given to Messrs. Weedon and Irish, of Sunderland.

THE QUEENSLAND TELEGRAPHS.—The Government has been calling for tenders for a telegraph line to Cape York, with a view to an extension to Thursday Island. The length of the line to be constructed is about 400 miles.

PROPOSED ELECTRIC LIGHTING OF MOSCOW.—The Municipal Council of Moscow, in Russia, are making enquiries with a view to eliciting the best means to be adopted for the proper and efficient lighting by electricity of that town.

THE INTERNATIONAL TELEGRAPHS CONFERENCE.—A Rio de Janeiro telegram states that Señor Capanema has left for London on his way to Berlin, where he will represent Brazil at the International Telegraph Conference, which will meet on August 10.

COPPER MINING IN NEW ZEALAND.—The Nelson *Mail* states that news had been received that good copper had been struck in the Doctor's Lode, and in the Champion Lode in the Champion Company's mine, at points where it has not yet been found before.

NEW SIGNAL STATION.—A Lloyd's signal station is about to be established at Anaga Point, on the Island of Santa Cruz de Teneriffe. The station will be in telegraphic communication with this country by means of the cable recently laid connecting Teneriffe with Cadiz.

NEW CABLE.—The laying of a new telegraph cable between Aberdeen and the Shetland Islands was completed on Tuesday last by the cable ship "Monarch." The cable will be of great value in the development of the herring fishing industry, in which fast steamers are now employed.

LONG DISTANCE TELEPHONY.—The Van Rysselberghe system in Belgium has now been extended to Louvain, which is 30 kilometres (or 19 miles) distant from Brussels, and over 40 kilometres (or 25 miles) distant from Antwerp, the first centre that was connected with the capital.

ANNIVERSARY OF THE FIRST ATLANTIC CABLE.—To celebrate the twenty-seventh anniversary of the completion of the first Atlantic cable, Mr. Cyrus Field will give a dinner on 5th August, when the American Minister and many representatives of the telegraphic world will be present.

THE SWAN LAMP IN GERMANY.—We have received a telegram from Mr. C. H. Stearn, Berlin, announcing that the Appeal Court have revoked the injunction prohibiting Naglo Brothers from using Swan lamps. This injunction, it will be remembered, was granted by the inferior Court in Berlin.

APPOINTMENT.—The Swiss Federal Council at a recent meeting nominated M. Emile Eschbœcher, Chef de Bureau to the Minister of Posts and Telegraphs in France, to the office of Secretaire du Bureau Internationale des Administrations Télégraphiques, left vacant by the death of M. de St. Martial.

A NOVEL EXHIBITION.—An exhibition will be held in Lille, France, on the 6th of next September, of different apparatus, chiefly electrical, for the purpose of giving alarm in case of fire. An interesting feature of the exhibition will also be a number of the latest and most approved patterns of safety lamps.

THE ELECTRIC LIGHT AT ESHER.—The Prince of Wales honoured the Hon. H. Bourke by visiting Nelville House, Esher, on Saturday last. The beautiful and extensive grounds were most effectively illuminated for the garden *fête*, a remarkable effect being produced by the illumination of the entire lake by electric light.

TEMPORARY SUSPENSION OF THE TELEPHONE SYSTEM IN BERLIN.—During the thunderstorms of the 14th inst., the electrical disturbance of the atmosphere in Berlin had such an effect upon the telephone system that it was considered necessary to consult the safety of the officials by suspending the service until the storms were over.

UNDERGROUND WIRES IN BROOKLYN, U.S.A.—The following Commissioners of Electrical Subways for the City of Brooklyn have been appointed under the amended State law relating to the putting of telegraph and other electric wires underground :—Professor George W. Plympton and Messrs. Rossiter W. Raymond and John Reynolds.

THE CITY AND GUILDS OF LONDON INSTITUTE.—Prof. Ayrton, F.R.S., will give at the Central Institution, Exhibition-road, a course of lectures and laboratory instruction for technical teachers and others, on the "Teaching of Electrical Engineering," the course to commence on the 27th inst. Further particulars will be found in our advertisement columns.

UNIVERSITY COLLEGE, LONDON.—The Council of the University College, London, have instituted a Professorship of Electrical Engineering, and have appointed Dr. J. A. Fleming, who will retain his connection as advising electrician with the Edison and Swan Electric Light Company. The courses of lectures and demonstrations will commence in October.

A NEW VISUAL TELEGRAPH.—A new visual telegraph is now said to be in operation between Guadeloupe and La Martinique, by means of an intermediate station at Marie-Galante. The speed of transmission is about a minute and a half per word, and two operators are required at each instrument. A French contemporary *naïvely* remarks that the cost of the installation of the apparatus is less than that of a telegraphic cable.

THE CRUTO INCANDESCENT LAMP.—The principal feature in the Cruto incandescent lamp is the method employed to obtain perfect homogeneity of the filament. This is effected by depositing the carbon very gradually upon a core of platinum, about 0·0004 inch in diameter, raised to incandescence by the passage of a current while in the midst of a

Digitized by Google

hydro-carbon gas. The result is a carbon of great density, the pores of which are infinitesimal.

THE LATE STORM IN THE METROPOLIS.—On Monday night the metropolis was visited by a storm of rain of an exceedingly violent description. About a quarter to nine o'clock rain began to descend smartly. The downpour increased in force about nine o'clock, and ultimately culminated in a violent storm. During the storm there were several very brilliant flashes of lightning, instantly followed by loud peals of thunder. No damage to life has, however, been reported.

CUBA SUBMARINE TELEGRAPH COMPANY.—At a meeting of the board of directors of this company, held on Wednesday, the audited accounts for the half year to June 30 were submitted, and it was resolved, after providing for the dividend on the preference shares and placing £3,500 to the reserve fund, to recommend the payment of a dividend on the ordinary shares at the rate of 10 per cent. per annum free of income tax, leaving £810 to be carried forward to the current half year's account.

NEW BRAZILIAN CABLE.—It is said that a contract has been concluded securing to the Central and South American Telegraph Company a concession to establish cables between Buenos Ayres and Rio de Janeiro; and land lines between Buenos Ayres and the Pacific side, thus securing to an American company continuous and independent telegraphic communication between the United States and Brazil. The necessary decree has been signed by the President of the Argentine Republic.

THE SUBMARINE TELEGRAPH CABLES BILL.—The Western Union Telegraph Company, the Commercial Cable Company, the Compagnie Français du Télégraphe de Paris à New York, and Siemens Brothers and Company have petitioned the House of Lords, praying to be heard by counsel against the Submarine Telegraph Cables Bill. This measure, which has for its object to carry into effect an International Convention for the protection of submarine cables, has already passed the House of Commons.

TELEGRAPHS ACTS (AMENDMENT) BILL.—On Monday last Lord John Manners, in reply to a question, said that his right hon. friend the Chancellor of the Exchequer would endeavour to find an opportunity for the consideration of this Bill, and when it reached committee stage he himself would propose some amendments. That would give the House a fair opportunity of dealing with the whole question. It was the hope of the Government that the measure would be passed into law this session. Mr. Shaw-Lefevre said that the course proposed by the right hon. gentleman was most satisfactory.

LIGHTING CONTRACT FOR BELGIUM.—The Belgian Minister for Railways, Posts, and Telegraphs announces that on Wednesday, 19th August, a ten years' contract will be let at the Brussels Bourse for lighting part of the Montigny station by gas or electricity. In the latter case the contractor will have to provide the building, motors, dynamos, leads, stores, labour, and all accessories, and maintain the same during the term of the contract. The Government reserves the right of taking over the installation at a price, decreasing each year, to be named in the tender.

A WONDERFUL BATTERY!—A story comes from San Francisco of a small bichromate of potassium cell, which is said to induce a current sufficient to overcome the resistance of over 5,000 miles of No. 10 galvanised iron wire. It is claimed that this invention will mark a new era in telegraphy, doing away with the huge batteries and dynamo machines now in use, and thus effecting a saving, as estimated, of £200,000 annually in America alone. It is a curious and interesting fact that, no matter how tin-pot the contrivance may be, it is always going to mark a new era or bring about a revolution in science. What do they burn, think you?

LONG DISTANCE TELEPHONY IN ENGLAND.—Experiments with the telephone of an important character were recently made by the officials of the Post Office, and the question whether oral communication between London and other distant centres of commerce is possible was placed beyond doubt, the result of the experiments being eminently satisfactory. The trial was made between Uxbridge, fifteen miles west of London, and Liverpool. The distance is 200 miles, and the tests satisfied the operators that it is possible to communicate between centres twice that distance apart, a return wire being used in this instance. The articulation was very distinct.

ANOTHER INDUCTION TELEGRAPH.—We are informed that Mr. Edison and others have invented a plan by which telegraphic communication between moving trains and also between the trains and various stations along the road can be carried on successfully. This consists of a canvas covered copper foil along the sides of the cars. By this means, it is said, messages can be taken from the wires, as they are now strung from forty to sixty feet from the train. The foil can be painted so as to be entirely hidden from view and will operate as well as if exposed to the air. This is probably identical with the system already noticed in our columns.

THE GLOBE TELEGRAPH AND TRUST COMPANY.—The directors of this company at the board meeting held on the 7th inst. decided to recommend the payment of a final dividend on and after the 28th inst. of 3s. per share on the preference shares, less income tax, and of 3s. per share on the ordinary shares (income tax having already been deducted), making, with the former distributions, a total dividend of 6 per cent. on the preference shares, and 4½ per cent. on the ordinary shares for the financial year ending the 18th inst., carrying forward a balance of £1,791. 15s. 5d. The transfer books were ordered to be closed from the 20th to the 28th inst., both days inclusive.

LAW AND ELECTRICITY.—Mr. J. H. A. Macdonald, Dean of Faculty, Q.C., lately appointed Lord Advocate for Scotland, is one of the most distinguished associates of the Society of Telegraph-Engineers and Electricians. His versatility has manifested itself both in his inventions and in his contributions to literature, which have been of a varied character. A few years ago he invented a holophote course indicator for the prevention of collisions at sea, and for this he received a bronze medal from the jury of the International Electrical Exhibition at Sydenham in 1882, and in the same year a certificate of honourable mention from the Exhibition of Means for Protecting and Preserving Human Life.

THE TELEPHONE IN AMERICA.—The total number of telephone exchanges in existence in America on 1st January, 1885, was 772. The number of miles of wire in use, 101,734, and of *employés*, 5,168. The subscribers amounted to 134,847. The increase in the number of subscribers during the year 1884 was 11,222. The annual subscriptions in different parts of the country are as follows:—In New York, £30; in Cincinnati, £35; Boston, £25; Baltimore, £25; Philadelphia, £25; New Orleans, £25; St. Louis, £25; and Chicago, £26. Against these the charges in some other parts of the world may be cited, such for instance as Paris, £24; Melbourne, £20; Sydney, £20; Moscow, £25; and St. Petersburg, £25.

PHOTOGRAPHS OF LIGHTNING.—Photographs of flashes of lightning have lately been obtained by Dr. Kayser, and he

Digitized by Google

has communicated the results of his experiments to the Berlin Academy. The lightning is shown to have proceeded very often from one point to several points, the aspect in the photograph being like that of a river with numerous branches. It was noticed that the feebler lightning flashes did not radiate in this manner. In one instance the stem did not only consist of one bright line, but of four lines parallel throughout, the second being like a band stratified transversely. Dr. Kayser explains this effect owing to the oscillating discharge, though he cannot assign any reason for the stratified appearance of the band.

THE TELEGRAPHS BILL.—The secretary of the Manchester Chamber of Commerce has written as follows to the *Manchester Courier*:—In answer to sundry inquiries at this chamber, perhaps you will allow me to say that on receipt of the news of the possible dropping of the Bill providing for so-called sixpenny telegrams, which was read a second time on the 22nd May, the president of the chamber (Mr. J. F. Hutton) addressed a letter to the Postmaster-General urging the great importance of reconsidering his decision, and expressing the earnest hope of the directors of the chamber that the Bill might be permitted to pass on to the committee stage without delay. So far no reply has been received to Mr. Hutton's letter.

THE TORPEDO SCARE.—Admiral Hobart Pasha, who seems to know what he is writing about, has recently published a pamphlet upon the use of torpedoes, both for purposes of attack and of defence. During the course of his remarks he says:—"I have visited the really wonderful establishment of Messrs. Latimer Clark and Co. There I saw every sort of invention in torpedo mines for coast defence. What astonished me was their simplicity, their cheapness, and so far as I could judge, their efficiency. The principal thing that struck me was the system they propose to adopt for laying down their ground mines. Simplicity, safety from accident, tremendous powers of local offence and defence, were clearly demonstrated in what I saw at these interesting works."

TELEPHONE RATES IN MANCHESTER.—A deputation of subscribers recently waited upon the directors of the Lancashire and Cheshire Telephonic Exchange Company at the head office in Manchester for the purpose of urging that the present rental rate of £20 should be reduced. Having heard the views of the deputation, Mr. C. Moseley, the chairman of the directors, replied at length to statements which had been made upon the subject in letters to the newspapers. He intimated that, in justice to the shareholders, the directors could not, under existing arrangements, reduce the rate, but that a new method of manipulation was under consideration which, if it stood the tests about to be applied to it, might lead to a reduced charge under certain conditions.

BOOKS RECEIVED.—"Second Edition of the International Inventions Exhibition Official Catalogue," including in the introductory portion a full section in connection with the electric lighting, and Sir Francis Bolton's description of the fountains and illuminations; and in the catalogue proper detailed descriptions of the Austro-Hungarian and other sections. A noteworthy feature of this edition is the exhaustive subject index, which will greatly facilitate reference to the exhibits.—"Minutes of the Proceedings of the Institution of Civil Engineers."—"The Journal of the Society of Telegraph Engineers and Electricians," No. 57, Vol. XIV.—"Hanbuch der Elektrotechnik," Bearbeitet von Dr. Erasmus Kittler, of Professor un der Grossherzogl, Technischen Hochshule in Darmstadt.

THE ELECTRIC LIGHT AT AN "AT HOME."—At the "At home" given by Mr. Thos. Cordes, M.P., at Hill-street, Berkeley-square, on the 9th inst., Messrs. A. R. Sennett and Co. temporarily installed the electric light; upwards of 100 lamps being employed. The spaces lighted comprised the grand staircase (by means of a large electrolier and lamps hung upon tree ferns), the two drawing rooms (by means of lamps placed on the cornices, glasses, curtains, &c.), the great ball room (by means of a very large crystal electrolier), and dining room. In the latter case the lighting was effected entirely by means of a number of 10 candle-power lamps, supported by the flowers used for the decoration of the supper tables. The electric lighting was much admired, and gave great satisfaction.

PROPERLY PUNISHED.—At a recent church festival at Cotopaxi, Mexico, a band of thieves conspired to extinguish the electric lights in the cathedral, and take advantage of the confusion and darkness to rob the people assembled there. The leader of the gang threw a wire over the electric light wire with the intention of drawing it down. As the ingenious but insufficiently-informed gentleman was not acquainted with the nature of shunt circuits the result must have somewhat surprised him. A sufficient amount of the current passed through his body to kill him instantly, while the members of the gang made good their escape in the confusion caused by the tragic death of their leader.

ELECTRIC LIGHTING IN THE CITY.—At a meeting of the City Commissioners of Sewers at Guildhall, on Tuesday afternoon, Mr. J. V. Moore moved "That, having regard to the repeated failures of private companies to supply electricity, it is desirable that the Commission do undertake street-lighting by electricity, and that it be referred to the Streets Committee to select a small area and to obtain estimates of costs of installation." He said that when they considered that the electric light was a success in many places, it was greatly to be regretted that in the city they should be without the light. The Commission were the lighting authority of the city, and had ample powers and means to carry out any system they might adopt. An experiment would not cost more than £1,500. After some discussion an amendment was moved by Mr. Deputy Ashby, and accepted by Mr. Moore, by which the whole matter was referred generally to the Streets Committee to inquire into and report.

BECHUANALAND.—The revenue from the new territory, derivable from the Cape Customs, an Imperial contribution, the police allowance, the land receipts, the hut tax, and stamps, is £63,000, and the expenditure is estimated at £62,000. Provision will be made for the official establishments and legislative expenses, as well as telegraphs, and interest on a loan of £36,000 for public works. The latest news, according to a contemporary, from the Telegraph Section in Bechuanaland, is that Major Jelf, R.E., Director of Military Telegraphs, has returned from a tour of inspection along the existing line, and has brought up with him stores for 300 miles more if required. The line will at once be run up to Kanya and Monopolole, and possibly eventually to Shoshong, the capital of Khama's country, and within measurable distance of the Zambesi. Lieut. Anstruther, R.E., remains at Mafeking in charge of the portion of line, Mafeking to Vryburg, and Sergeant-Major Cole, R.E., of the southernmost portion, Vryburg to Barkly.

THE AMET ELECTRIC GOVERNOR.—According to an American contemporary a modification of the Amet electric governor for the purpose of regulating the currents produced by dynamo electric generators has recently been perfected. The need of this device in cases where two or more dynamos are driven

Digitized by Google

from one source of power is self-evident, as the steam governor can control but one dynamo or one series of dynamos on a single circuit, as it controls by varying the speed to suit the amount of current required. Mr. Amet calls his device a brush regulator, and where it is used the speed is kept constant and the point of delivery on the generator changed to compensate for any and all changes in the resistance to be overcome. As demonstrated by the tests, a dynamo may be short-circuited at full speed without injury to the machine, and any number of lamps may be thrown in or out of circuit. The apparatus steadies the lamps, and does away with about 20 per cent. of the flickering, the lamps remaining at a normal brilliancy whether two or twenty are burning. A constant current is maintained, and all changes are instantaneously compensated for.

Trials Made at Turin and at Lanzo on the Distribution of Electric Light to Great Distances.—According to the *Proceedings* of the Institution of Civil Engineers, an electrical Exhibition has been held at Turin, and important prizes have been offered by the Italian Government and by the City, of which the following facts have been communicated to the academy by M. H. Tresca :—Messrs. Gaulard and Gibbs have established between the Exhibition, the station at Lanzo and intermediate stations, a circuit of 80 kilometres length, with a chrome-bronze wire, of 3·7 millimetres diameter. This wire is traversed by alternating currents produced by a Siemens machine of 30 horse-power. The following lights were worked from the circuit with the intervention of Messrs. Gaulard and Gibbs' secondary or induction apparatus; at the Exhibition, 9 Bernstein lamps, 1 Soleil lamp, 1 Siemens lamp, 9 Swan lamps, and 5 other Bernstein lamps at a short distance, all, however, needing very different electromotive forces. At the station of Turin-Lanzo, 10 kilometres distant, 34 Edison lamps of 16 candles, 48 of 8 candles, and a Siemens arc lamp. Later there were added at the station at Lanzo, 40 kilometres distant, 24 Swan lamps of 100 volts. The lighting was perfectly regular, and easily independently extinguished and illuminated.

The Telephone and Fires.—On the 12th inst. a fire broke out in the warehouse premises of Messrs. Spicer and Co., in John-street West, Blackfriars-road, and eventually completely destroyed a five-floored warehouse, used for various purposes, besides causing other damage. Intimation of the outbreak was conveyed to the head-quarters of the Metropolitan Fire Brigade in Southwark Bridge-road. On the arrival of the steamer it was found that a very strong fire was already raging on the premises. Superintendent Hamlyn, when he arrived from Kennington, saw the serious nature of the fire, and telephoned for engines, which arrived in rapid succession from Waterloo road, Tooley-street, Old Kent-road, Peckham, Brixton, Clapham, Chandos-street, and other stations. In the course of half an hour, by means of the rapid circulation of the alarm, there were eight steamers pouring water from different points upon the fire. An outbreak of a most destructive character also took place on Monday among the property of Messrs, Smith and Co., timber merchants, &c., No. 11 Arch, Howley-place, Belvedere-road, Lambeth. The alarm quickly spread, communication with the Telephone Exchange being effected through the firm of Mr. J. S. Gabriel, Nos. 67 and 69, Belvedere-road, causing it to be "switched on" to head-quarters, Southwark Bridge-road. A strong force of the members of the Metropolitan Fire Brigade was prompt in response to the summons, and steamers from head-quarters, Kennington-lane, Tooley-street, Camberwell, Rotherhithe, Old Kent-road, &c., attended,

The Earthquakes.—A Reuter's telegram, dated Simla, July 9, announces that shocks of earthquake continue to be felt in Cashmere at intervals of two or three days. A severe shock occurred at Srinagar on the 4th inst. A telegram from Calcutta on Tuesday last announces that a smart earthquake shock was felt there at 6:25 a.m. The houses rocked violently for several seconds. A sharp shock of earthquake, accompanied by a loud rumbling noise, was felt at Kopreinitz in Styria on the night of June 28, which was followed by two others the following morning. Several houses were thrown down and other damage done. A new theory as to the origin and cause of earthquakes has, says *Nature*, been propounded by the Viceroy of the Chinese provinces of Shensi and Kansu. In a recent memorial to the throne, published in the *Peking Gazette*, this high official describes an earthquake which occurred on January 15 in various parts of Kansu, and summarises briefly the various reports which he has received on the subject relating to the motion, the damage done (which in some places was extensive), and the measures taken for the relief of the sufferers. He then proceeds to say that for years past earthquake shocks have been so frequent in these regions that people have grown quite accustomed to them; indeed, one officer informs him that in certain villages there were indications of a movement of the earth every night during the fourth watch, but these always ceased after a heavy fall of snow. The memorialist concludes by attributing the earthquake to the mildness of the winter, which caused an excess of the *yang*, or male element of Nature; "but it was due in a measure also to the perfunctory performance of their public duties by the local officials, who thereby failed to call down the harmonising influence of Heaven, and the memorialist can only endeavour to remedy this fault by encouraging his subordinates to cultivate habits of introspection and examination of their own shortcomings, himself setting the example." A shock of earthquake occurred at Valez-Malaga on Monday night, but no damage was caused. A smart shock of earthquake also occurred at Smyrna at half-past 1 o'clock on morning of the 15th inst. The vibration was also slightly felt at Chesmé.

Electric Light Applied to Firearms.—Last week we recorded the application of a miniature electric lamp to the front sight of a rifle; and now intelligence reaches us of the same idea having been worked out independently in France, while a lamp of greater power, intensified by a projector, has been fitted to the end of the muzzle, for throwing a strong light on the object aimed at, the light only being shown at the moment of firing, through contact being made by the pressure of the butt end of the piece against the shoulder. These two inventions, by M. Gustave Trouvé, of Paris, formed the subject of a communication to the French Academy of Science on Monday, July 6. The luminous fore sight, no larger than an ordinary metallic sight, consists of a fine platinum wire, enclosed in a glass tube, which is protected by a metal case having a slit opposite the back sight, so that, when contact is made, the luminous line is only visible by the person aiming, while the light is not sufficiently powerful to give out lateral rays perceptible to the enemy, for instance. The current for the lamp is supplied by a bi-sulphate of mercury battery, no larger than the finger, attached to the barrel by two india rubber bands, while the leads are put in connection with the poles by elastic clips. The battery consists of a cylindrical ebonite cell, with a zinc and carbon couple occupying the upper half, and diluted sulphate of mercury the lower, so that it only comes into action when the piece is levelled for firing. For throwing a strong light on the object aimed at—and this application is more especially

Digitized by Google

useful in war for repelling night attacks—a Hélot-Trouvé projector is attached to the muzzle of the rifle by india rubber bands. The projector, such as is used for surgical purposes and for throwing a strong light on objects for the microscope, consists of a tube, carrying in the middle an incandescent lamp with a single straight filament, while at the back is a reflecting mirror, and at the front a condensing lens with adjustment. A small bichromate of potash battery is carried by the belt or the cross belt, and a metallic contact is fitted to the butt end of the piece, so that the light is projected only at the moment of firing. At the same time the projector furnishes a safe lamp for entering powder magazines, &c.

THE ELECTROLYTIC REDUCTION OF FINE COPPER FROM ITS ORES.—The Italian Copper Mining and Electro-metallurgical Company, of Genoa, has received the second prize of 5,000 lire, and the process which has been adopted for some time past at their works at Casarza, near Sestri-Ponente, is described in the *Proceedings* of the Institution of Civil Engineers, as follows :—The plant includes twenty Siemens electrolytic dynamos, giving a current of 250 amperes, at 15 volts tension, each of which serves twelve reducing baths. Part of the ore, varying in amount according to circumstances, is smelted to a coarse metal, containing copper 30, sulphur 30, and iron 40 per cent., which serves as the anode. Another part of the ore is roasted and lixiviated to form a solution containing as much copper sulphate as is required to render the ferrous sulphate of the anode useful for the electrolytic decomposition of the copper salt. The order of the operation is as follows :—Preparation of the anodes : The ore intended for this purpose is smelted for coarse regulus in the usual way. The regulus is cast into thin slabs, a strip of copper being placed in the mould to form the conductor for the current. The anodes so prepared are placed in the decompositing cells, thin sheets of copper being used as cathodes.—Preparation of the solution : The ore roasted so as to produce the necessary sulphate for the bath is systematically lixiviated with an addition of sulphuric acid to dissolve any oxide of copper formed in roasting the liquor, containing copper and iron sulphate, is kept in tanks and added to the bath as required. The copper sulphate is decomposed by the electric current, copper being deposited on the cathode, while the anode is attacked with the formation of iron salts and sulphuric acid, which prevents the deposit of iron and the evolution of hydrogen, so that the copper deposits in a compact and chemically pure form. The saturation and proper composition of the solution is maintained by connecting the baths by pipes with the lixiviating vats, so that a constant and regular circulation of the liquor is kept up. The solution has a sufficient oxidising power to dissolve up metallic sulphides, in some cases without requiring a preliminary roasting. The greater part of the electromotive force necessary for the decomposition of the copper sulphate is furnished by the oxidation of iron in the anode, so that for the remaining work in the bath an electromotive force not exceeding one volt is sufficent. The exhausted anode may be utilised for the reproduction of sulphur or sulphuric acid. When the solution is overloaded with iron vitriol it is removed from the bath, and the last traces of copper are recovered by precipitation with sulphuretted hydrogen, which is produced by adding regulus to the acid liquor. At the same time the iron salts are reduced to ferrous sulphate, and the free sulphuric acid is neutralised. The iron vitriol may be recovered by crystallising, otherwise the liquors containing it, when freed from copper, are run to waste. If the baths are properly arranged, and care be taken to keep the liquors in circulation at the proper strength, a maximum yield of 44lb. of copper per horse-power employed may be obtained daily. The process appears to be particularly well adapted for mines in mountain districts where water-power is readily obtainable, but which, owing to the difficulty of obtaining, and the high cost of mineral fuel, are unfavourably placed for smelting operations.

THE TELEPHONE AT LIEGE.—A public meeting has been held at Liége, Belgium, under the auspices of the Chamber of Commerce, to support the application of M. de Locht, for a Government concession for establishing a telephone exchange in opposition to the Bell Company. The De Locht telephone was adopted for the first exchange at Buenos Ayres, but was replaced by the Bell telephone, in the same way that the Bell Company have absorbed the Gower telephone in Brussels and the Bède telephone in Liége. M. de Locht offers generally a reduction of 50 per cent. in the subscriptions, as compared with those at present maintained by the Bell Company, which has the monopoly. He proposes, within a radius of 2½ kilometres or 1½ mile, a fixed subscription of 50 francs or £2 per annum, with a tax of 15 centimes or three-halfpence per call up to 500, and 10 centimes or 1d. for every call above that number up to 2,500, after which there would be no tax. Beyond the radius named, the additional subscription would be 25 francs (£1) per kilometre (0·62 mile) per annum, so that for a distance of 10 kilometres or 6 miles, the annual subscription with the maximum number of calls would only amount to 390 francs (£15. 12s.) against 600 francs (£24) asked by the Bell Company. It came out in the discussion that the present Minister of Railways, Posts, and Telegraphs was opposed to competition—that he feared it would ruin the present company, some shares in which, it appeared, were held by members of the department. A resolution was passed unanimously, pledging the meeting to support M. de Locht's application. On Tuesday last week the subject was brought before the Chamber by M. Hanssens, who said that the question was one of public interest, but the Minister appeared to throw every obstacle in the way of any competition with the Bell Company. M. Vandenbeereboom, Minister of Railways, Posts, and Telegraphs, said that numerous petitions had been addressed to the Chamber in support of M. de Locht's application for a telephone concession in opposition to the Bell Company, all based on the principle of the liberty of competition. M. de Locht promised a reduction in the subscription, which should have its due weight, but the organisation, and indeed the existence of the service, must be taken into consideration. Experience had proved that a multiplicity of concessions brought about a complete disorganisation of the telephone service. Scarcely three years ago there were three companies in Brussels, and two each at Antwerp and Liége, which, after a hard struggle, had to combine with a considerable increase in the subscriptions. It was now acknowledged that to ensure a good service there should be only one telephone company, as everywhere, after a forced lowering of rates, resulting from ruinous competition, there was a considerable increase. When the Government came into possession of the telephone system, which it had the right to assume in seven years it would have to undo all that was not according to system, at great expense, which would necessarily increase the subscriptions, and all the more so as each system was incorporated in the scheme of long distance telephony. M. Somzée said that if the telephone companies retained the monopoly the country would not get the full benefit of the invention on account of the high rates of subscription. He was in favour of the taking over of all the telephone lines by the State. Ultimately the petition was referred to the Ministry of Railways, Posts, and Telegraphs.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 135.)

The Principle of Thermal Resistance.

Suppose we, with a sure faith in the truth of the principle of Conservation of Energy, and a knowledge of the equivalence of work and heat, observe that the motion of a magnet in the neighbourhood of a closed circuit generates heat in it, that this ceases when the motion ceases, and that we satisfy ourselves that this heat is the only final result of the motion, so far as energy is concerned. This heat must be the equivalent of work done. As we have no reason to suppose that the magnet is in a different state at the end from what is was in at the beginning of the motion, we cannot attribute the heat to a loss of potential energy by the magnet. Hence we may conclude that the heat is the equivalent of work done against resistance to the motion of the magnet. That is to say, however the magnet move, its motion is resisted. Here we have Lenz's law, without any reference to the direction of the current induced in the circuit, but merely as regards conservation. In fact we made no mention of current. If now we bring in other knowledge, that there is a current induced in the circuit, the heat being proportional to the square of its strength, we are still left without means of determining its direction in a given case. Only finally, when we utilise Ampère's determination of the mutual forces between magnets and currents can we exactly say in which direction the induced current will be in a given case, for it must always be such as to resist the motion.

Lenz's law is not, however, the subject of the present section, but is used to point out the distinction between the above kind of resistance to motion and the kind involved in the Principle of Thermal Resistance, to which we now proceed. It is such a large subject, and there are so many ways of treating it, that it is difficult to know how to begin; after consideration I adopt a method which I have not met with, and which is therefore, if not novel, at least unusual; believing that, whether it be better or worse than other methods, there is advantage in viewing a truth from all possible sides, to allow another law, that of the survival of the fittest, which, like that of thermal resistance, results from averages, to have a chance of operating.

We cannot, in general, alter the configuration of a body without doing work upon it, or letting the body do work. Considering any solid elastic body, for example, a straight wire: we cannot twist it without doing work. The motion is therefore resisted. On the other hand, if we let the wire untwist it can do work itself against external resistance. Here, of course, we must have conservation of energy when all actions are taken into account, and nothing novel so far is presented. But there is, during the changes of configuration of an elastic body, another kind of resistance brought into play, depending upon the rate of change of configuration, at least, usually. Suppose we twist a wire slowly, and at every stage of the process note exactly the amount of the applied force, or do the same by small instalments. By summation we know the total work done in producing a given twist. Similarly, if we let the wire untwist slowly by small instalments, the force will be the same in the same configuration as during the twisting, and the same amount of work will be done by the body. But if we twist the wire *suddenly* to the same extent as before *more* work will have to be done, or there will be an additional resistance to the motion at every moment, and if the wire suddenly untwist, it will do *less* work, or again, there is a resistance to the motion which did not exist before.

We may put it this way: If we measure statically the forces in different configurations we do not by summation get the total work done. There is always an additional resistance to the motion, opposing the change of configuration, never assisting it. I call this thermal resistance, because, whenever it occurs, there is a thermal effect also produced. It is not, however, necessarily a heating, as one might expect, but may be either a heating or a cooling. But, whichever it be, the change of configuration is always resisted. That is the cardinal fact that must be remembered.

If, during the change of configuration, the body be allowed to part with or to receive heat so as to neutralise the thermal effect if it be a heating or a cooling respectively (as by conducting the operation very slowly, and not thermally insulating the body), the thermal resistance itself is evanescent. On the other hand, if the body be thermally insulated, so that heat cannot leave or enter it, it will be of the full amount. This will serve to elucidate the effect above mentioned of *suddenly* changing the configuration. We thus give no time for heat to escape or be taken in appreciably. Now given this law, or principle of thermal resistance, and a statement of one effect upon a body, deduce another. I give a few examples.

(1). We observe that heat lengthens and cold shortens a bar. What should be the thermal effect of suddenly stretching it? It must be such as to oppose the stretching; that is, to shorten the bar, and is therefore a cooling.

(2). What should be the effect of removing the stretching force? To oppose the return to the unstretched length, therefore to lengthen the bar; therefore a heating.

(3). Water above 4° C. expands by heating, what is the effect of compression? Such as to oppose the compression; therefore a heating.

[Notice there are two effects—the thermal resistance and the heating or cooling effect.]

(4). Water below 4° C. contracts by heating. The effect of compression is, therefore, to cool it, as the compression is thereby resisted.

(5). Water expands in vaporising. Hence pressure raises the boiling point.

(6). Water expands in freezing. Hence pressure lowers the freezing point.

(7). An india rubber band at ordinary temperatures, stretched by a weight, lifts it when heated. What should result from suddenly stretching the band? The motion must be resisted; that is the invariable fact. The thermal effect is therefore a heating, for that, by the previous, lifts a weight.

(8). A twisted wire is suddenly twisted further. Is it a heating or a cooling effect that is produced? Whichever it be it must increase the torsional rigidity, so as to oppose the twisting. If, then, heat lessens the torsional rigidity, it is a cooling effect, and conversely.

(9). Compressing a gas heats it. Hence heat applied to a gas increases its pressure, for this is the only way to make the compression be additionally resisted. This property of a gas is so well-known that it is more difficult to recognise the principle. It is hard to imagine the possibility of a gas being cooled, by compression. Yet the principle involved is identically the same as in the less obvious illustrations.

Other mechanical illustrations may be multiplied indefinitely, but the above will be sufficient. When we wish to go further, and make applications to electricity or magnetism, it is necessary to be very particular that the necessary conditions are complied with. The thermal resisting force is always opposed to the motion, and so far resembles a frictional force; but the thermal effect, unlike that of friction, is reversible with the direction of motion, and the motion produced by heat is reversed if cold be applied. Thus, during the stretching of a spring, the pull of the spring is $F+f$, if F be what it would be if there were no thermal effect, and f is the small increase produced by, or accompanying it. On the other hand, when the spring shortens, the strength of force is $F-f$ at a corresponding stage, and at the same temperature, f being the same quantity as before. Regarding the forces as vectors, F is constant in direction, f changes, being with F in the stretching, and against it in the unstretching. That is, it is always against the direction of motion. The heat effect, if it be a cooling during the stretching, is a heating during the unstretching. And as regards the effect of heat, if heating increases, cooling must decrease the elasticity. If in some peculiar state, both heating and cooling produced the same effect on the elasticity, or if either stretching or unstretching produced the same thermal effect, we could not

Digitized by Google

immediately apply the principle without reservation. Further investigation would be needed.

(10). Given a circuit of two metals A and B, at one temperature initially. We observe that slightly heating one junction causes a current from A to B, and cooling it causes a current from B to A. Here is a perfectly reversible thermal effect, although accompanied by other strictly irreversible effects in the circuit. In accordance with the principle, what should be the thermal effect at the same junction on passing a current from an external source from A to B? The current must be made weaker than it would otherwise be, hence the current due to the thermal effect is from B to A, hence it is a cooling, by the previous knowledge. At the other junction it must be a heating, for the current is there from A to B. Thus there is a transfer of heat from the first junction to the second. Notice the peculiarity that the thermoelectric force in the circuit, due to both junctions weakens the main current; that is the first conclusion. But the E.M.F. at both junctions is from A to B, whence it follows that at the first junction the E.M.F. is weaker than at the second. Further inquiries would lead us to the full theory of thermo-electricity.

(11). Given that the capacity of a condenser is increased by heating and decreased by cooling the dielectric, what should be the thermal effect of suddenly charging it? The charging must be opposed, hence a decrease of capacity or a cooling effect. Similarly, suddenly discharging the condenser should produce a heating effect, which we may conclude thus:—The discharge must be resisted. Now, the rate of discharge depends upon the difference of potential of the ends of the discharge wire. This must be reduced therefore. But a reduction of potential with the same charge means an increase of capacity, for which there must be, by the above, a heating effect. Observe here that these thermal effects are independent of the absorption phenomenon.

(12). A curious result of thermal resistance is that a perfectly elastic solid, if such really existed, vibrating, would come to rest without any external or internal friction to cause it. Thus in a vibrating spring, thermal resistance opposes its motion whether it be moving to or from the equilibrium position. Now, if the spring could give out and take in heat instantaneously, so as to keep its temperature constant, the effect would vanish, and, without friction, the spring go on for ever. Similarly, if the spring could be thermally insulated, the cooling and heating effects produced when moving to or from the equilibrium position would balance, and the spring could go on for ever. But practically, neither one nor the other condition can be complied with, and the spring must be brought to rest without friction entirely by the thermal effect being practically radiated or conducted away in one motion, without an exactly counterbalancing receipt of heat in the opposite motion.

There is another way of looking at the principle which is useful, viz., to direct attention to the flow of heat into or out of the body when it is being strained, supposing that the body is, in the first place, in thermal equilibrium with its environment, and that it can receive or lose heat instantaneously. Thus, in example (9), compressing a gas drives heat out of it. Now, go to the other end of the operation. Take heat out of a gas. It compresses itself. Or take example (1). Stretching a bar draws heat into it, and sending heat into a bar makes it stretch itself. From this point of view we regard two events as being invariably connected, motion of matter of a certain type, and a flow of heat in a certain way. But the method is less general than the preceding, assuming, as it does, that the flow of heat is always permitted, likewise the motion.

In all cases whatever in which the principle of thermal resistance has been experimentally tested, it has been found to be correctly followed by Nature. Can we then assert its invariable truth, and apply the principle unhesitatingly to hitherto unverified cases, possibly unverifiable? Is it possible to give a rigid demonstration of its truth? The first question may be answered in the affirmative, the latter not. We cannot prove it even as we prove the truth of conservation of energy, viz., by seeing that it is a necessary truth in pure dynamics, and extending our notions to all the operations of nature, observing that it is experimentally true in a great many cases, convincing ourselves of its universal application with the assistance of a little faith. For we cannot deduce the principle of thermal resistance from the laws of dynamics. It would be no breach of conservation of energy were it to be exactly reversed, were strains to be assisted by thermal effects. All we can really do is to convince ourselves that, being true in all observed cases, and its negation leading to extraordinary consequences which are *not* observed, though not dynamically impossible *à priori*, it must, by faith, be generally true.

First, put the principle in a mathematical form. Let an elastic body be strained from one configuration to another, keeping it always at one temperature t, to allow which a quantity of heat H leaves the body, whilst W is the work done upon the body. Then the principle asserts simply that $d\mathrm{W}/dt \div \mathrm{H}$ is positive, or that $d\mathrm{W}/dt$ and H are either both positive or both negative, which is easily verified by the above examples. More work is caused to be done by the thermal effect if it be not than if it be allowed to escape.

Next, to see the consequences of its negation, follow the example of the founder of thermodynamics, Sadi Carnot, wher, in the most masterly and scientific manner, he set to work to find the cause of the motive power of heat. After the above strain, bring the body back exactly to its original state through the same series of intermediate configurations, but at a slightly different temperature $t+dt$. This requires there to be two other operations (2nd and 4th), viz., to raise the temperature by dt in the second configuration, and to lower it by dt when it has got back to the first. Now the body does work $\mathrm{W}+\frac{d\mathrm{W}}{dt}dt$ at the higher temperature. Hence, in the complete cycle, the body does work $\frac{d\mathrm{W}}{dt}dt$. What else happens is that an amount of heat H is lowered in temperature by the amount dt. Now, without any experience to guide us, H and $d\mathrm{W}/dt$ may be algebraically positive or negative, and not of the same sign necessarily. But if they could be of opposite signs, work would be obtained through a substance *raising* the temperature of heat. If then we take it as axiomatic that it is impossible by conveying heat from a cold to a hot body to obtain mechanical effect, then we prove that the law of thermal resistance is universally true, at least for bodies in mass, and inanimate.

Now this axiom, so called, is really the principle Carnot was led to, viz., work is derived from heat by *lowering* its temperature. Carnot's principle is thus a consequence of the principle of thermal resistance. In Carnot's cycle for a gas engine heat is taken in at a higher and given out at a lower temperature, and the pressure is greater at the higher than at the lower, so that the gas does more work in expanding than in being compressed back to its original state, and thus we have finally heat lowered in temperature, and work done by the gas. In his water and vapour cycle it is similar, so he concluded that the necessary condition of obtaining work by thermal agency was the lowering the temperature of heat. He was only wrong as regards the *quantity* of heat lowered in temperature.

Now this being a consequence of the principle of thermal resistance, and the various examples above given being commonly regarded as consequences of the Second Law of Thermodynamics, with which Carnot was most assuredly not acquainted, how is it that Carnot was acquainted with *them*? I do not say he thought of them all. But he knew some of them, and, had he been asked what would be the result in a given case, according to his principle, he would have given the correct answer. Only his reason for the answer would have been erroneous. For the only legitimate reason that Carnot could have for applying his principle universally would be that he had proved that all reversible engines had the same efficiency between the same temperatures, so that his principle, known to be true for one body, must be true for all.

But this proof was vitisted by his erroneous assumption of the materiality of heat, then universally believed in, and was only put right long after, by Clausius and Thomson, on the basis of the equivalence of heat and work, fully established experimentally by Joule. Carnot founded his proof on a perfectly unexceptionable axiom (on his view of the nature of

Digitized by Google

heat). Work could be obtained without any thermal agency if all reversible engines had not the same efficiency between the same temperatures. The substituted axioms of Clausius and Thomson are by no means so satisfying, considered as axioms. They express truths, they involve Carnot's principle, they involve the principle from which Carnot's is derived, but they are not axioms, unless a law of nature, only to be learnt by experience, is an axiom.

Clausius said that heat will not pass from cold to hot by itself, or without compensation. True enough, by definition of cold and hot, if the cold and hot bodies be in contact. Otherwise not self-evidently true, though a law of Nature. Thomson said we cannot get work out of a body by cooling it below the lowest temperature of surrounding objects. This I also admit to be true, knowing that it involves Carnot's principle, and believing that, but it is not self-evidently true. A third axiom that can be used is that we cannot convert heat into work without lowering the temperature of heat. This, I believe to be the best of all, being the simplest expression of the truth of Carnot's principle that work is got by lowering the temperature of heat.

Of course Carnot was wrong in his quantitative estimate of the efficiency of reversible engines, but his principle remains unaltered. When, with the principle of thermal resistance, we combine that of the equivalence of work and heat, and use Carnot's criterion of the perfection of an engine, that it must be reversible, we arrive at an absolute measure of temperature independent of any particular substance, and using it, give quantitative expression to the principle of thermal resistance, viz. :—

$$dW/dt = H/t,$$

where t is temperature according to the scale of equal dilatations of an imaginary perfect gas under constant pressure, whose energy, at constant temperature, is independent of its volume. It now becomes a form of the Second Law of Thermodynamics.

There is a reason for everything, and therefore (if that be an axiom) for the axioms of thermodynamics, better called laws. The reason of conservation of energy the student of dynamics can understand, if he can grant that the laws of matter in motion observed in masses are true for the smallest parts of bodies. The reason of thermal resistance is also, by the aid of the kinetic theory of gases, becoming evident, and will no doubt some day be established for all bodies. It arises from the irregular nature of the motions we call heat. We cannot control single molecules. Could we do so, down would go the law of thermal resistance and heat could be converted straight into work, molecular irregular motions to an equivalent amount of motion of a mass, the irregularity disappearing, without at the same time having to lower the temperature of another quantity of heat, as at present required. But what we cannot do with inanimate matter may be going on always to a certain extent in living matter; not because living matter is exempt from any law of Nature, but that we do not yet know all its laws. The perpetual running down of the available energy of the universe is a matter that must be cleared up. It is incredible that it can always have been going on, and dismal in its final result if uninterrupted. It is therefore the duty of every thermo-dynamitist to look out for a way of escape.

(To be continued.)

A NEW DYNAMO.

A contemporary, the Italian journal *Il Giorno*, illustrates a new dynamo recently constructed at the Tecnomasio in Milan, the design of which will be understood by reference to our annexed engravings. The bedplate of this machine is a heavy circular ring of cast iron, having at diametrically opposite points vertical extensions to which the field-magnets are attached. The latter are in line with each other, and it is claimed for this arrangement that the magnetic field is thereby made very symmetrical and intense. A similar disposition is found in the Hochhausen, the Van Depoele, the Türgensen, and the Thury dynamos, but in all these the masses of iron which serve as yokes are too near the poles, and disturb the field to a considerable extent. To judge from the illustration the new dynamo seems, however, to require a great deal of wire on the field-magnets, and it certainly requires more floor space than most of our compact English machines. The latter objection has been overcome in the vertical arrangement, which we also illustrate. The armature in this case is driven by a pair of friction cones and two belts running in opposite sense. In

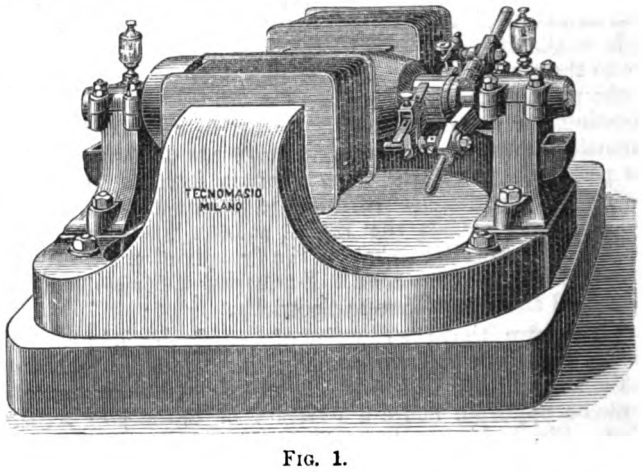

FIG. 1.

this way all side thrust on the bearing is balanced, and a device which permits the armature with its cone to be slightly raised or lowered serves to stop and start the armature. The chief reason for arranging the armature vertically is to overcome the difficulty of vibration in the spindle of horizontal armatures when the bearings are a great distance apart. According to the makers of this machine, a

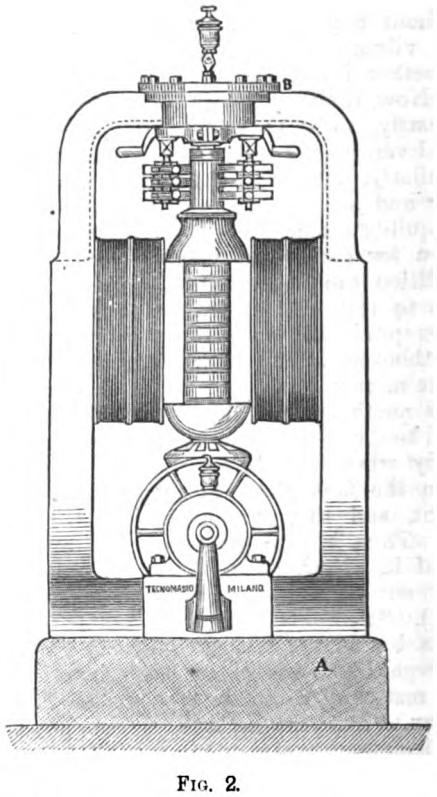

FIG. 2.

drum armature should be as long as possible, so as to give a maximum of electromotive force with a minimum of wire, and to make a very long armature mechanically possible they were obliged to resort to the vertical arrangement.

The soundness of this reasoning is, however, open to doubt. At the present time the tendency seems rather to be in the direction of short armatures of comparatively large diameter, as a cursory glance over the machines at the Inventions

Digitized by Google

Exhibition will show. However, we cannot as yet say that a state of finality has been reached in the construction of

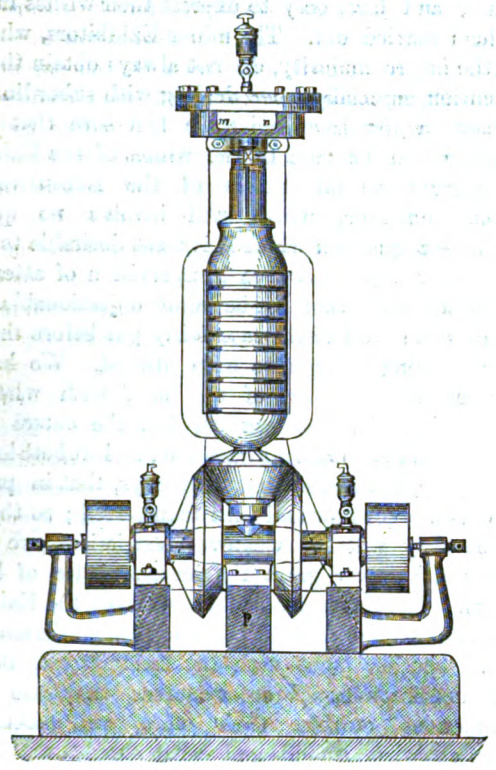

FIG. 3.

dynamos, and as the arrangements adopted by the "Tecnomasio" have at least the merit of novelty they deserve some attention.

LITERATURE.

Gas Engines By WILLIAM MACGREGOR. [London: Symons and Co. 1885.]

To write a first book on a subject which comprises the results of the work of a good many is not an easy task. To compile a book from the fragmentary writings of others is a much less difficult task, but it is still a troublesome work, and one which is likely in the end to be characterised as "paste and scissors." We will not describe Mr. MacGregor's book as worthy of this brief description, and we will give him credit for what he has done, and the difficulties he has had to encounter in this comparatively untrodden field of mechanical literature; but we must admit that we are disappointed. The author shows very considerable intimacy with the subject upon which he has written. He possesses a good deal of knowledge on the design, construction, and "nasty temper" of gas engines. But there is a world of gas engine lore that those behind the scenes possess which has not entered into the possession of the director of Mr. MacGregor's pen, or, at any rate, has not been published in his book. He has probably found that gas-engine builders are reticent, and object to tell him all that they have learned at enormous cost; he has been obliged to depend largely upon patent specifications, which, as every one knows, seldom contain the precise forms of detail which experience has, subsequent to the drawing of the patent drawings, found essential to success; and he frequently finds it necessary to say something of the same order as that at p. 97, where he remarks that "all of Atkinson's motors present novelties of ignition, regulation, and distribution that I regret it is beyond the scope of this work to consider." We might ask why, and with respect to the paragraph quoted, the reply would perhaps be that as some of Mr. Atkinson's novelties are not now used by him, it is not necessary to describe them. That the author has not been able to obtain satisfactorily complete drawings is a fault in the book with which we must not charge him, though we may object to the omission of the names of the inventors of the engines on the plates, while the words "MacGregor Gas Engine" are printed very large on each of them. The author's preface is not consistent with the book. When he wrote the preface the thermodynamics of the gas engine seemed to be a literary red rag, for speaking of these and of the cycles of Carnot, he says that "all reference to the cycles of Carnot and to the engine considered as a theoretical heat engine have been very carefully avoided. For in practice the gas engine has no affinity whatever to these cycles, except such as a straining of the truth to so great an extent as to exclude the effect of the most important practical factors as the cooling effect of cylinder walls might obtain. This is very clearly proved by a careful and unbiassed study of the practical cycles of the machine as given by the indicator diagram, and as involved in the consideration of the superior efficiency of high piston velocities. The superior economy of compression engines, and the relatively closely succeeding standard of the free piston engines, are facts that have not yet been satisfactorily correlated by any merely theoretical thermodynamic consideration." This is a curious mixture of truth and fiction, for whatever the effects of compression and high velocity of piston, the applicability of thermodynamics to any question of the efficiency of the engine as a heat engine remains the same, and it must be pointed out that that is not a "theoretic thermodynamic consideration" of the subject which does not take fully into account the whole of the practical conditions and facts involved. It is true that Carnot's cycle is not approximated to in the cycle in which a gas engine works, but the author is very far from escaping the application of thermo-dynamics to a consideration of the engine as a heat engine in the very copious extracts he gives from Mr. Dugald Clerk's paper on the theory of the gas engine read before the Institution of Civil Engineers in 1882.

A few words more and we have done with complaints. In those parts of the book which are of the author's composition a little more care might have been bestowed on the mode of expression. To the uninitiated, for instance, it would be difficult to understand the following, noted amongst other points which mark the Otto engine as distinct from its predecessors:—"By better employment of the heat generated in consequence of the cooling of the cylinder;" and again "the smaller powers use on an average 1 cubic metre per horse-power the hour, whilst for the larger constructions the consumption of gas is modified to about $\frac{3}{4}$ cubic metre," meaning that by the larger engines the consumption is reduced to $\frac{3}{4}$ cubic metre. What the following concerning Lenoir engines means is also enigmatic:—"Besides the advantage of a better and more economical expenditure of the gas by compression of the mixture before combustion, a gradual tension of the chief organ of the engine also assists this, and as well contributes to the object of a completely non-recoiling action." The reader of Mr. MacGregor's book is, it would appear, supposed to be perfectly cosmopolitan as to measures of all kinds, for we have in different parts, according as he is making up from one source or another, gas in cubic feet, cubic metres in another, and in litres in another; heat in British units and in centigrade units; work in ft. lbs. and kilogrammetres; length in feet, elsewhere in metres; cost in shillings and elsewhere in dollars. Temperature is, however, uniformly in centigrade units.

Now, of the book we may say that it is one which was very much wanted. For the greater part it is a compilation of more or less copious extracts from papers and reports, German, French, American, and English. The author has fairly taken the substance of these, although he might with advantage have given the diagram of the Crossley engine which accompanies Prof. Thurston's report published in *Van Nostrand's Engineering Magazine*, and from which he quotes extensively.

The book is valuable for its historic notice of the subject, and gives a good deal of information not generally known, showing how several inventors approached very near to success. That there is not much of original work in the book need not detract from its value, and although it is easy to see that much remains to be written on the gas engine, we have no hesitation in saying that Mr. MacGregor's work is one that should be in the possession of everyone interested in its subject.

EXHIBITORS AT THE INVENTORIES.

It will be seen from our correspondence columns that the Exhibitors at the South Kensington Exhibition feel that they suffer from grievances sufficiently strong to induce collective action. Since the opening of the Exhibition, complaints, verbal and otherwise, have reached us from the Exhibitors. We are rather slow in accepting as real all the little troubles that arise, but when we hear so continuously, and from so many sources, of mismanagement we cannot but think there is a reason for such complaint. Exhibitors are apt to forget the difficulties of organisation that beset the Executive. They imagine that their own particular grievance is the only one of magnitude, and often too hastily infer that the Executive is indifferent to their claims. Then the Executive is very much in the hands of *employés*, who may or may not carry out instructions with tact and discretion. It would be difficult to obtain so large a staff as is employed at the Inventories without finding by experience that some of its members are worse than inefficient. On the other hand, the Executive may look upon the ordinary exhibitor more like the pawn upon a chess board than as having any proper standing in the concern. Certain Exhibitors can always command attention to their requirements, and have only to express their wishes in order to have them carried out. The minor Exhibitors, who however form the larger majority, do not always obtain the same careful attention, especially when dealing with subordinates.

In the case of the Inventories, we feel sure that immediate attention will be paid to the wishes of the Exhibitors if fairly brought to the notice of the Executive. Let us take one example, which will involve no question of personality—a question which it is most desirable to avoid. The trouble over the renewal and supervision of attendants' tickets is on all sides said to be most objectionable. The Executive cannot have had the case fairly put before them, or the rules would long since have been altered. We have no knowledge of the members of the staff with whom the assistants are brought into contact, but the curses at the method and manner of treatment have been and are both loud and deep. It may be, as our correspondent says, that in previous years the tickets were now and then transferred; so they are now, and so they will be, whatever restrictions are placed upon them, and however great the inconvenience of holders getting them. The Executive could well meet the Exhibitors in this, and thus a large amount of unnecessary friction would be avoided. Another point with the Exhibitors is that the "walking superintendents," or whatever they are called, assume functions outside their office, and dictate to the Exhibitors what should and what should not appear upon the stalls. This has, we believe, been especially noticeable in the Electrical Section—so much so, in fact, that an almost unanimous agreement has been come to that the Exhibitors will withdraw their exhibits entirely. Collective action in this way would be a disaster, and in the interests of Exhibitors, the public, and the Executive, we may mention that when direct appeal has been made to the highest authorties it has resulted in the retention of the portions of exhibits objected to.

The Exhibition cannot exist without Exhibitors, and it is in the interest of every one desiring the success of the South Kensington work to assist in getting rid of defects and getting the machine to work smoothly. Were we in a captious mood we could give some very startling information about South Kensington, but we are fain to think that many things will, if left quietly alone, in some way or other right themselves. The question of the rules and regulations applying to exhibitions is, however, of pressing importance, and we shall offer the proposed Association every facility for placing their views clearly and forcibly before the Executive. We have sufficient faith in the business capacity of the Executive to foretel that any reasonable demand put forward by the Exhibitors will be granted without delay. *Bis dat qui cito dat* is probably the motto of the Executive, and we should be greatly surprised if it were not followed to the letter. No doubt the facilities offered by exhibitions for pure business purposes are discounted by the Exhibitors, and although it may be put forward that philanthropy and education are the mainsprings at work, these have to give place to the more practical question—Will it or does it pay directly or indirectly? If, therefore, the Executive were not to keep a pretty firm course, its work in the end would resolve itself into the management of a big bazaar and pleasure gardens. However far the real may be from the ideal, it is certain that South Kensington is expected to be more than a big bazaar, and the Executive something different from the directors of a public company, with the sole object of earning a dividend upon the capital invested.

SIXPENNY TELEGRAMS.—A NEW PHASE.

Following on the decision of the Government to give every facility for the discussion of Mr. Shaw-Lefevre's Bill we have now what appears to be a semi-official announcement that his successor at the Post Office will submit an amendment to the House embodying the principle of Free Addresses, and "will abide by the result." This is news of some gravity; for an amendment of that kind will certainly find much support, and if pushed on in earnest may possibly be carried. In the interests of the public, as well as of the Telegraph Service, the new Postmaster-General will do well to "abide" in the sense of having saved appearances, and allow his political followers to remain equally passive. By this time he must have in his possession sufficient data to prove that Free Addresses are incompatible with any substantial reduction of the Tariff, which is the only thing the House or the public cares about.

But supposing Lord John Manners presses his amendment with enthusiasm, and Mr. Shaw-Lefevre offers it only a half-hearted opposition, what, we should like to know, is his lordship's alternative scheme? To simply reduce the charge to sixpence is utterly out of the question. Even to reduce the charge to sixpence, and the text of the telegram to ten or twelve instead of twenty words, giving the addresses free, would imply that either the late Postmaster-General's estimates and calculations were all wrong, or else that the present holder of the office thinks he can induce the Treasury to incur the enormous additional expense involved in signalling ten or a dozen extra words upon each telegram without charging more for it than Mr. Lefevre proposed to charge. Twelve words for sixpence was the utmost the late Government were prepared to offer; and even at that rate the new Postmaster-General has discovered that the prospective outlay had been seriously underestimated or disregarded. He will therefore hardly have the temerity to increase the limit to twenty or two-and-twenty words for the same money.

If Free Addresses are to be maintained with a reduced charge, the only alternative, it seems to us, is to reduce the existing rate a little, and the maximum text a good deal. Ninepence for ten words, with the addresses thrown in, is an alternative Tariff that might possibly pay, and we see no other. As the Department sends twenty-seven words for a shilling at present, it could perhaps afford to send twenty words for ninepence, especially as a ninepenny tariff would not be so oppressively popular as to necessitate a further large outlay on plant and staff in two or three years' time. But this question of popularity is the very essence of both the rival schemes; and the House will have to determine which of the two will be most popular—a ninepenny tariff, with the addresses free, or a sixpenny tariff with the addresses charged for. On grounds which have been stated many times in these columns we prefer the latter, or indeed any reasonably liberal tariff which at the same time charges for the addresses as an essential part of the message as a whole. And on this account we hope that some friendly understanding has been arrived at between the late and the new chief of the Post Office, so that the one may carry his Bill while the other will save his conscience.

THE E.M.F. OF THE RETINA.—Many efforts have been made to ascertain the E.M.F. of the retina and nerve of the eye, and to learn whether this quantity undergoes any alteration under the action of light. Some recent experiments have demonstrated the fact that the action of light is such as to vary the amount of electromotive force to the extent of about 3 to 7 per cent. of the total force. A strong flash of light enduring for the fractional part of a second produces, therefore, a marked effect.

CORRESPONDENCE.

SECONDARY BATTERIES: AN ELECTRO-CHEMICAL QUESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to perceive from your columns that M. Faure is continuing his work in connection with secondary batteries.

In regard to the question which has been raised as to the theory of the lead secondary couple, it is very necessary in the first place to exercise some care to avoid misapprehension, and, in the second place, to speak with some degree of diffidence, since it is sufficiently evident that there is much to be learned in this direction. If the "generally-accepted explanation" which is expressed by the equation,

$$Pb + PbO_2 + 2H_2SO_4 = 2PbSO_4 + 2H_2O,$$

be intended merely to embody the fact that in the working of the battery *some* peroxide is converted into sulphate, simultaneously with the conversion into the same salt of an equivalent of metallic lead, the theory in question cannot be controverted. Further than this, I think it may be admitted that, starting with an equivalent of spongy lead as the active material of the positive element, and an equivalent of lead peroxide as the active material of the negative element, it is *possible*, in presence of sulphuric acid in slight excess, to convert the whole of the active material into sulphate of lead by simply circuiting the couple. To obtain this result, which in my view is due to the fact that any compound which may be formed by residual lead peroxide is more or less rapidly decomposed by sulphuric acid (which would ultimately obtain sufficient access to it), a lengthy period of time would be necessary; for the initial potential difference of about two volts, remaining nearly constant until the peroxide had undergone a certain modification, would afterwards, with constantly diminishing rapidity, fall to zero.

But what I would venture to deny, on the basis of my own experience, is that this explanation is applicable to the conditions of practice. It fails to take into account essential details or steps in the chemical reaction which are revealed by variations in the potential-difference exhibited by the elements of the couple. In practice we consider a secondary cell to be quite discharged when the potential-difference falls to 1·8. In practice, again, I have found it expedient, with a view to diminishing the ratio of weight to useful work, to allow two equivalents of lead peroxide in the negative to each equivalent of oxidisable metal in the positive element. In practice (instead of the spent negatives being coated with a layer of white sulphate), the purple-brown colour—with something like a plum bloom and a peculiar softness of surface—which we love to see in the freshly-charged negative has merely changed to a light reddish-brown, or to a "cut chocolate" colour mottled with dark brown, and this tint extends throughout the substance of the element. In practice, any portion of the spent negative—whether from the surface or from the interior—evolves chlorine gas when treated with hydrochloric acid, *i.e.*, contains peroxide of lead, either free or combined.

Another suggestive fact is, that in the case of an insufficiently charged peroxide plate—where much peroxide has been formed, but in which some portion of oxide remains unconverted—we invariably fail to obtain, with an efficient spongy-lead positive, a potential-difference as high as two volts.

Now the questions—of equal interest in theory and in practice—which present themselves for solution are these:—

1. What proportion of the peroxide of lead present in an efficient negative element, mainly or wholly composed of this compound, is available for useful discharge, *i.e.*, for the production of a current under the potential-difference of about two volts, or not less than 1·8 volt?

2. To what cause is to be ascribed the comparative inefficiency of the residual peroxide, which, though abundantly present, either in a free or in a combined condition, gives with an efficient lead positive a potential-difference below 1·8 volt, and possibly much below 1 volt?

It may be some time before these questions can receive a

Digitized by Google

satisfactory elucidation. I do not claim to be in a position to afford such an elucidation. I do not consider that my hypothesis, at the best, is more than an approximation to the truth. According to my suggestion, the reaction expressed by the equation given above—a reaction which I admit as *possible*, though not as *practical*—should, from an electrical point of view, be divided into at least two stages, indicated by the variation of potential. In this reaction, equivalents of lead and of peroxide of lead, with two equivalents of sulphuric acid, become converted into two equivalents of sulphate of lead and two equivalents of water. Doubling, for the sake of convenience, the number of equivalents involved, my suggestion is that the two steps or stages—neglecting complications due to the more or less perfect access of sulphuric acid to the interior of the negative element—would be as follow:—

(*a*). Giving a potential difference of about two volts.

$$2Pb + 2PbO_2 + 4H_2SO_4 = PbSO_4 + Pb_2O_3 + Pb + 3H_2SO_4 + H_2O.$$

During a period in which this stage overlaps the next stage, the potential falls more or less rapidly to about 1·8 volt.

(*b*). Giving an initial potential difference of about 1·8 volt, falling gradually to zero.

$$Pb + Pb_2O_3 + 3H_2SO_4 = 3PbSO_4 + 3H_2O.$$

When the useful discharge, due to the former reaction, is alone considered, equation (*a*), by subtraction from both sides of the residual quantities, involved in equation (*b*), of course becomes identical with the second equation given in my former communication.

I may mention that I have recently constructed two cells with spongy-lead positives; in one of which (A) a coil of platinum wire, constituting the negative, is in contact with lead peroxide; whilst in the other (B) a similar coil was surrounded with sesquioxide of lead (Pb_2O_3). In both cases the electrolyte is dilute sulphuric acid, in quantity more than sufficient to convert the lead compound into sulphate. In cell B the bright red colour of the sesquioxide has been almost completely converted into brown by the effect of the acid. I have just measured the potential differences of these two cells, which I find to be on open circuit as follow:—

A gives 1·99 volt.
B gives 1·79 volt.

When the reaction between the sesquioxide and the acid had only partially occurred, cell B gave 1·26 volt.

Professor Tribe somewhat underrates, I think, the stability of the sesquioxide of lead. If my memory serves me rightly, M. Levol, who in 1841 made a very careful investigation into the nature of the red lead compounds, characterises the sesquioxide as "a compound of remarkable stability"—an expression which I reproduced in my former letter. No doubt it is completely decomposed even by very diluted sulphuric and nitric acid; but the reaction is by no means as energetic as might be supposed. Those who have had occesion to prepare the peroxide of lead from minium, and who have experienced the difficulty of removing the last portions of monoxide by washing with nitric acid, may confirm this observation. In this operation the minium must be very finely levigated, and be digested in the first place with *boiling* dilute nitric acid. Even after this, much washing with nitric acid is requisite, in order to obtain the peroxide in a state of purity. In regard to the action of diluted sulphuric acid upon the sesquioxide, I recently added 520 grains of this compound to a mixture of one fluid drachm of sulphuric acid (sp. g. 1·84) with 10 fluid ounces of water. Although the weight of sesquioxide was sufficient to neutralise the acid, and did ultimately neutralise it, the mixture, in spite of energetic stirring, remained strongly acid for several hours. In this case the sesquioxide was in a condition of very fine subdivision. Had it been in the form of dense fragments the neutralisation of the acid would, I believe, have been practically an impossibility.

Mr. Swinburne, I observe, is sceptical as to the existence of such a compound as the sesquioxide of lead. He may obtain it, however, by treating any sample of "genuine" red lead with a solution either of potassic hydrate or of the normal acetate of lead until no more oxide of lead is dissolved. In the hydrated form the same compound may be precipitated by adding a solution of oxide of lead in potassic hydrate to a solution of potassic plumbate. Having obtained the compound Mr. Swinburne might be interested in testing its stability by subjecting it, in the first place, to the action of solutions of oxalic and of sulphurous acid.—Yours, &c.,

DESMOND G. FITZGERALD.

EXHIBITORS AT THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On behalf of many exhibitors in the International Inventions Exhibition, and on my own account, I venture to submit to you, for publication in your well known paper, the following remarks as to the position and treatment of the exhibitors and their assistants (not attendants).

Premising that the success of the Exhibition is mainly due to the exhibitors, not only for the great teaching value and generally interesting nature of their exhibits, but also for the wide reaching influence they possess, in inducing their friends and business people to take an interest in, and to visit the Exhibition, I ask, what equivalent or counter advantage is given to them for the enormous money and brain outlay they have contributed, and for the continuing expense of attending their exhibits? My own experience is that absolutely nothing is given in return. It is an exploded notion that business results from exhibitions, or at least sufficient to pay the expense, and I venture to say that this is the opinion of most of the exhibitors after the two months' trial at the present Exhibition. Not only is there no equivalent, but the exhibitors are utterly ignored, only and excepting so far as they lend themselves and their exhibits to the money-making of the Exhibition. The bandsmen, waiters, and others have their recognised position, and are provided for, the official staff have their offices and club rooms; but the exhibitors, who make the Exhibition, are treated with an extent of coercion and repression which is unprecedented in any other Exhibition, and which has culminated in deep and serious murmurings and a feeling of discontent which will take a great deal to allay. The contrast between the treatment of exhibitors in this Exhibition and similar foreign exhibitions is most marked, and to those who have exhibited in both it is most humiliating.

The following are briefly the grievances of the exhibitors and their assistants:—

There is no writing or reading room for their use; there is no suitable lavatory provision; the weekly renewal of passes is most unnecessary and objectionable; the restrictions as to the limit of time and use of the passes should be abolished; complimentary tickets should be given to the exhibitors both for *fête* nights and other occasions; the subway toll should not be charged to exhibitors and their assistants. There are other and individual complaints which should receive consideration.

As to the renewal of the passes, my own recent experience will be interesting:—Owing to the absence of one of my assistants, I considered it better, to satisfy the officials, to use his ticket myself, which I did, attending and having it clipped for five days in succession. I presented the ticket for renewal, and was told by an officious gentleman in the office that because I had written my name across the ticket in pencil (there being no convenience to write it in ink, and no rule to that effect) instead of in ink, he would not renew my ticket! a culmination of red-tapeism than which anything more absurd or ludicrous it is impossible to imagine. I appealed at once to the secretary, and my appeal was at once attended to. Unfortunately the head man in the "*Attendants' Passes Office*" (I had been refused by his subordinate) was not in his office, so that I could not get the pass renewed that day (Monday), and in the meantime my exhibit is accumulating in dust. I mention this to show to what the officiousness of these subordinates is tending, and how necessary it is that action be taken at once.

An "Exhibitors' Association" has been formed, and a great many of the exhibitors and their assistants have already approved, and no doubt all the others who have not yet been

Digitized by Google

solicited to do so will join. The objects of the association, as far as at present contemplated, are :—

1. To secure united action amongst the exhibitors and their assistants, to remedy grievances, and secure advantages.

2. To make exhibitors and their assistants known to each other for recommendation and mutual benefit.

The association is not inimical in any way whatever to the Executive Council, and is regarded with the greatest respect by each and all the members of that Council. We propose in due course to submit our grievances to the Executive, with the certain and assured feeling that our reasonable complaints have only to be known to be remedied. It is possible that an exhibitors' association may be of great assistance to the Council in future exhibitions, and help to ensure their success. On that account, I venture to hope it may receive the good wishes and support of the Council.

I have heard that the objection to giving assistants a pass for the whole of the Exhibition is that during the last Exhibition the passes were used by other than assistants. Suppose they were, the Exhibition was nevertheless a financial success, and surely the exhibitors and their assistants are entitled to some little grace. That the passes were used by others in a past Exhibition is not a good reason for treating the present exhibitors and their assistants with the suspicion and overbearing that is now the case.

As the representative journal of perhaps the greatest exh bit in the Exhibition, the "electrical and electric light," will you be good enough to give the association your valuable support, the use of your offices for meetings, and in other ways as you may think best ?—Yours, &c. HENRY B. JOEL.

Tower-chambers, Moorgate-street, London, E.C.,
14th July, 1885.

[We are quite willing to give the Association all the facilities it requires to place the views of the Exhibitors before the Executive.—ED. *E.*]

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the "Exhibition Record" of 10th inst., p. 17, second column, lines 6, 7, 8, you say: "The two latter machines are running a high-speed Armington and Sims engine."

As the above statement is a little puzzling, seeing that the engine is running the two machines instead of the two machines running the engine, we should be glad if you would kindly correct that part of your notice, and oblige—Yours, &c.,

GREENWOOD AND BATLEY,
Sole makers of the Armington-Sims engine.

Albion Works, Leeds, July 14, 1885.

[The word "running" should have been replaced by the words "run by." The error is so obvious that it scarcely requires mentioning.—ED. *E.*]

ON A METHOD OF LOCALISING A PARTIAL EARTH IN A CABLE WHEN A RETURN WIRE IS NOT OBTAINABLE.

BY J. ANDERSON AND A. E. KENNELLY.

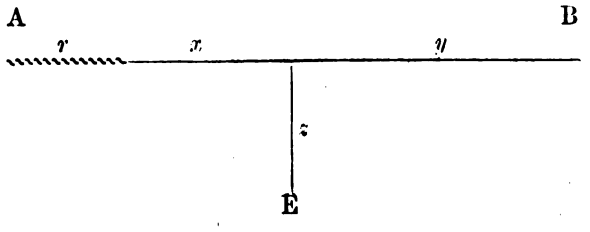
The method of fault-localisation herein described is based on no new principle, merely applying facts that have been known for many years, but which deserve more consideration at the hands of those who, like ourselves, have localisations to effect, and will, we hope, be interesting to electricians generally. In comparing theoretically methods of localisation and in estimating their relative value we have to ascertain the respective accuracies of which they are susceptible, and to what extent this accuracy is reduced by the probable behaviour of the fault during the tests.

The first consideration, that of the accuracy of measurement attainable, we may briefly name the sensitiveness of the method. This sensitiveness depends upon two things—one is the subdivision of units to which the required measurements can be carried, and is a purely physical factor; the other is the relation of the measured quantities to each other, in the formula giving the fault's distance, and is a purely algebraic matter. A good localisation method should possess sensitiveness in both these aspects—that is, it should be capable of considerable accuracy in the required measurements, and the numbers standing for those measurements should be so connected by the formula yielding the localisation that an error of observation in them may least vitiate the result.

The second consideration, above mentioned, the disturbance due to variation in the fault, is principally a physical matter depending upon the fault's position in the circuit, arrangements of the test, and its tendency to vary in electromotive force in consequence of that position. As it is obviously useless to acquire sensitiveness in localisation-methods, if that sensitiveness be annulled by the variations introduced by changes in the fault, it is necessary that a good method should have this source of error reduced to a minimum. This is usually sought by making the time which elapses between the measurements as short as possible, so that the fault may not have sensibly altered in condition between the two, and when the measurements can be taken simultaneously from each end of the cable this is best secured.

For the purposes of this paper there are only two methods which we need consider, and these are the Varley loop test and the Blavier test, with its modifications. We shall examine them in detail, and endeavour to show that the Varley loop test satisfies the requirements for a good method just stated in a high degree, and that the ordinary Blavier test does not possess those qualifications, but that modifications may be made of the Blavier method by which much of the value of the Varley test may be gained after due allowance is made for the loss of general efficiency through the absence of a loop or return wire.

In the Varley loop test the sensitiveness of measurement is high, for it has all the accuracy of which, under the particular circumstances of the test, the Wheatstone bridge, the most sensitive of measuring instruments, is capable. Its algebraic sensitiveness is also large, for any error of observation in the measurement of the resistance producing balance produces only half that error, in the result giving the fault's distance. Added to this, there is but little loss of sensitiveness through disturbance due to fault variation, for the loop test is practically a simultaneous measurement from each end of the line with a fault in the centre of it, so that variations of the fault affect each measurement equally and synchronously. We see, therefore, how fully the Varley loop test satisfies the conditions we have laid down for estimating the relative value of different methods, and the high rank it has always taken in practical value is thus accounted for. In fact it is only when the loop of cable is of great length and its normal insulation comparatively low that there is any uncertainty in the results given by it. We shall now examine the Blavier method with the aid of the accompanying figure.



A and B are two stations between which is a faulty cable of total normal conductor resistance l. x and y are the distances of the fault from each end of the cable, so that $x+y=l$. The resistance of the fault is z, and r is an adjustable resistance added to the end of x at station A.

In the ordinary Blavier test r is removed or is zero, and one or both stations measure the resistance of the line when the distant end is freed and earthed.

Let f be A's measurement when B frees.
„ f' „ B's „ „ A „
„ e „ A's „ „ B earths.
„ e' „ B's „ „ A „

Digitized by Google

Then supposing both stations tested, we obtain four equations by which the fault's position may be found.

$$x = \quad e - \sqrt{\{(f-e)\ (l-e)\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$x = l - e' + \sqrt{\{(f'-e')\ (l-e')\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$x = \frac{f}{2} - \frac{f'}{2} + \frac{l}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$x = e \times \frac{l-e'}{e-e'} \left\{ 1 - \sqrt{\frac{e'\ (l-e)}{e\ (l-e')}} \right\} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

The first two equations are similar, and the same reasoning will apply to both.

Theoretically, in the tests to which these two equations relate the measurement of f is perfectly sensitive, and e not perfectly, but sufficiently sensitive for all practical purposes; also there is no considerable want of sensitiveness in the equation algebraically. There is, however, much liability to disturbance in the measurements, owing to fault variation, and this generally prevents the method from yielding reliable results.

When the same battery power is employed for measuring f and e the fault is necessarily at a higher potential in the circuit for f than it is for e. Consequently, as the resistance of a fault is some function of the current passing through it, there is a tendency for the fault to vary between the measurements. This variation also affects the measurements unequally, for in f any variation of resistance v in the fault produces a corresponding change of v in the measurement of f, but the same variation of the fault in observing e produces a change of

$$\frac{y\ (z+v)}{y+z+v} - \frac{y\ z}{y+z}$$

$$= \frac{vy^2}{(y+z)\ (y+z+v)} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

$$= v\left(\frac{y}{y+z}\right)^2$$

approximately in the measurement of e. This quantity is, of course, always less than v.

The only means of reducing this source of error is to employ a smaller electromotive force in observing f than that for observing e, and we can approximate to the proper ratio between them by a simple calculation. This plan is practically the best to adopt in Blavier tests, but even then the polarisation of the fault alters between the two measurements, for earthing the cable at B makes y a shunt to z, and this source of error cannot be brought under control. It is, therefore, seldom that this formula enables a localisation to be satisfactorily effected.

Turning now to equation 3 we obtain a more promising combination. In the first place f and f' are both limited in sensitiveness only by the range of the measuring instrument, and in the next place, algebraically, there is a gain in sensitiveness for any error in observing f when f' is correct, or in observing f' when f is correct produces only half that error in x, the fault's distance. The liability to error is in such variation as may take place in the fault between the two measurements. This is best reduced by placing the fault at the same potential in each measurement, and in taking the measurements as quickly as possible after each other. Practically it is best to add resistance to the lesser of x and y until it is found that f and f' are equal, also employing at each end the same battery power and the same ratio in the arms of the bridges. The readings are taken to cable-current zero, and as swiftly in succession as may be. When this is done we obtain theoretically a Varley balance in everything but synchronism and exactness. The formula for the Varley balance also applies, for if r in the figure be the resistance that has by successive trials to be added to x in order to make $f = f'$, then

$$x = \frac{l-r}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

When for any reason the "fall of potential" method cannot be employed this test often gives good results. By maintaining the same strength and direction of current through the fault during each measurement the tendency of the fault to vary is reduced to a minimum. It frequently happens, however, that the resistance of the fault is so variable that, notwithstanding all precautions, f and f' cannot be properly measured. It is to meet such cases in a more suitable way that we bring to notice a method not yet published so far as we are aware. This method is a modification of equation 4, which we will now examine.

In this equation we notice that, instead of the gain in algebraic sensitiveness we have mentioned in equation 3, there is a considerable want of sensitiveness; for in the condition best for measurement and for least disturbance from fault variation, namely, when e is nearly equal to e', or when, that is to say, the fault is near the centre of the line, an error in observing e or e' produces a considerable error in the result, for the difference $e - e'$ is then the denominator of an improper fraction. If e and e' be very unequal it is then difficult to arrange the testing batteries at each end so that the strength of current passing through the fault shall be the same in each measurement, and it is impossible to maintain precisely comparable measurements, even though this were done, as the polarisation of the fault will alter in each case, being shunted by different resistances. Probably owing to these reasons this formula is seldom employed. One advantage, however, this case possesses, and that is the steadiness of e and e', compared with f and f' when the fault is very variable, as shown by Equation 5; in fact, the variations of the fault are shunted down.

In the method we bring to notice it is proposed to unite the advantages of equations 3 and 4 by adding resistance in successive trials to the lesser of x and y, until $e = e'$. When this is done another modification of Varley balance is obtained, and if r be the resistance added to x in order to make $e = e'$

then, as before, $$x = \frac{l-r}{2}$$

It is true that in order to obtain measurements less disturbed by fault variation this test, which we may call the balance of e and e', loses a certain amount of the theoretical sensitiveness of measurement possessed by the balance of f and f'; still, in practice when the fault is very variable, there is generally a decided gain on the whole from the absence of disturbance in these measurements.

In obtaining the balance between f and f', supposing the condition of the fault to be constant, r is obtained by one measurement of f and f', for it will be approximately $f' - f$; but in balancing e and e', r has to be found by successive approximations, for if $e' - e = n$ when $r = 0$, and we make $r = n$, then e'' will become

$$e' + n \times \frac{z^2}{(x+z)\ (x+z+n)} \quad . \quad . \quad . \quad . \quad (7)$$

and e will become $e + n$. So that the difference between the new values of e and e' has become reduced from n to $n \times \frac{z^2}{(x+z)\ (x+z+n)}$, and where n is small relatively to x and z this is approximately from

$$n \text{ to } n\left(\frac{z}{x+z}\right)^2$$

If, now, $n\left(\frac{z}{x+z}\right)^2$ be added to r, r will be $n + n\left(\frac{z}{x+x}\right)^2$ and the difference between e and e' will be further reduced to

$$n\left(\frac{z}{x+z}\right)^4$$

approximately; and so increasing r each time by the difference between e' and e, we should, supposing the fault constant, arrive at a difference between e' and e equal to q. Suppose where

$$n\left(\frac{z}{x+z}\right)^{2s} = q,$$

q would be the limit of appreciation for the measuring instrument, and s would be the number of values given to r in suc-

Digitized by Google

cession before balance was obtained. Suppose the original difference between e' and e to have been $50^{\omega} = n$, and $x = z$ also the limit of appreciation in measurement to be $0{\cdot}1^{\omega}$, then

S = between 5 and 6,

or balance would be found after r had been readjusted five times. Practically, however, instead of following this approximation process it would be preferable to ascertain roughly by some other method the value of r to be first tried, and then balance would soon be obtained except in so far as the variation of the fault would disturb the readings.

It is evident that the theoretical sensitiveness of this test is reached when (supposing the fault constant) a change made in r makes a change less than the limit of appreciation in the bridge at B. We can ascertain what degree of sensitiveness we obtain for any given cable and fault. This limit is reached when a change in r of an amount m produces the smallest appreciable difference in the reading at B.

Suppose that B can observe to μ units. When balance is nearly obtained, $x + r = y$ approximately.

Let $y + z = \phi$ and $\frac{yz}{y+z} = p$.

Then $$\left(y + m + \frac{yz}{y+z}\right) - \left\{y + \frac{z(y+m)}{y+z+m}\right\} = \mu$$

$$\therefore m + p - \frac{z(y+m)}{\phi + m} = \mu$$

$$\therefore m^2 + m(y - \mu + p) = \mu\phi$$

$$\therefore m = \frac{\sqrt{\{4\mu\phi + (y - \mu + p)^2\}} - (y - \mu + p)}{2}$$

or approximately $$m = \mu\left(\frac{y+z}{y+p}\right) \quad \ldots\ldots\ldots \quad (8)$$

Thus m is always greater than μ, and m diminishes as z increases relatively to y. That is to say, the greater the resistance of the fault is to the distance y, the less will be the sensitiveness of the measurement.

To take a case, suppose y to be 1000^{ω}, and z to be 5000^{ω}, and that A and B have bridges by which $0{\cdot}1^{\omega}$ can be appreciated, then

$$m = 0{\cdot}1\left(\frac{1000 + 5000}{1000 + 8333}\right)$$

$$= 0{\cdot}33^{\omega}.$$

Or, supposing the fault constant, and that A and B observe correctly, the fault could be localised to one-sixth of an ohm, since the added resistance r could be adjusted to one-third of an ohm. The method of balancing f against f' would in this case have theoretically localised the fault to one-twentieth of an ohm, but would have been much more subject to disturbance from fault variation.

The following are some readings that were obtained with an artificial fault made between two lengths of cable coiled in a tank. The fault was made purposely in such a manner as to give a somewhat high and variable resistance, x was 43^{ω}, y was 367^{ω}.

The resistance of the fault z by bridge from the end B with ten Leclanché's was found to be 400^{ω} at first, rising to 900^{ω}.

e' was then observed, while r was 0 e' was 440^{ω}

e was next taken with the same battery and direction of current

e was found to be 350^{ω}

r was then made 100^{ω}

e' was then 510^{ω} e considerably less

r was increased to 250^{ω}

e' was then 630^{ω} e still lower

r was next increased to 300^{ω}

e' was then 668^{ω} e still a little less

r was again increased to 350^{ω}

e' was then 709^{ω}; e more than e'

r then reduced to 325^{ω}

e' then 700^{ω}; e was a little more than e'

r was therefore reduced to 321^{ω}

e' was then found to be 695^{ω}; e was lower

r increased to 330^{ω}

e' then $694{\cdot}5^{\omega}$ e was then higher

r altered to 325^{ω}

e' was then found to be 693^{ω}
e ,, also ,, ,, 693 } Balance.

The correct resistance for balance would have been 324^{ω}.

The balance of f and f' was then tried with the same battery and direction of current (zinc to line), but nothing reliable could be obtained from the rapid variation of the fault. With copper to line, however, the fault was much steadier, and a good balance was obtained. Still, the balance of e against e' was obtained when it would have been impossible to get the readings of f and f', the above balance being 325^{ω}. The distance of fault $x = \frac{410 - 325}{2} = 42{\cdot}5^{\omega}$, the actual distance 43^{ω}—an error of half an ohm. In this case allowance must be made for the rapidity with which the readings could be made to follow each other, and the general increased chance of accuracy, through one observer and one set of instruments; but even after all deductions are made on these accounts the method shows itself to be a very useful one.

The *rationale* of the method in practice might be as follows:—A and B obtain an ordinary Blavier test to approximately localise the fault. This done they arrange to earth their ends alternately, adding to the lesser of x and y, suppose to x, the resistance r assumed to approach balance. B now observes e' while A earths, then communicates with A on the cable and gives him his measurement. This A inserts in his bridge and adjusts r until he obtains balance while B earths. A then earths and B again observes and so on until balance is obtained in each case with r. In both balancing f against f' and e against e', it is necessary that both observers read to false zero, and in the same general manner, otherwise their readings will not be comparable.

We have now described a method for localising variable faults which, although not so sensitive in point of measurement as the balance of f and f', or other tests, is, we think, more free from the troublesome disturbance of fault variation than any other on a single cable that we are acquainted with, and consequently one which we believe will be found useful. The theoretical limit of accuracy to which it is capable of being employed we have indicated, and an estimate has been furnished for the amount of depreciation in the results through fault variation by equation 5.

The method has already proved its value in one actual case, and that alone has amply returned the time given to its development. We trust that it may be found useful by others, and that it may at least occupy that place, whatever it may be, in the list of localising methods which experience shall prove it deserves.

Since writing the foregoing we have had an opportunity of applying the balance of e and e', which we may call the earth overlap test, to two cases in actual practice, with the following results:—

The first case was a cable over 600 nauts. in length, with an extremely variable fault 10 nauts. from one end; this fault had from $1{,}500^{\omega}$ to over $3{,}000^{\omega}$ resistance, and changed so rapidly that no reliable results could be obtained with any of the ordinary methods. The mean of a series of nine-earth overlap tests, however, localised the fault to within two and a half nauts. of its true position, while the widest variation between any two of these tests was about six nauts., which we consider satisfactory when the very variable nature of the fault is taken into account. In the second case the length of line was over 1,100 nauts. with a fault 150 nauts. from one end. This fault had about 550^{ω} resistance, and was

Digitized by Google

much steadier than in the first case. As there was a second line the result obtained by the earth overlap test, namely, 1,418$^{\omega}$, could be checked by a Varley loop, which gave 1,426$^{\omega}$, a difference of only three-quarters of a naut.

ON THE CALCULATION OF MAINS FOR THE DISTRIBUTION OF ELECTRICITY.*

BY W. H. SNELL, ASSOCIATE.

(Concluded from page 161.)

Now, as long as we have only or mainly to deal with lamps belonging to Group I. ("Regular" division), we can obtain nearly the true values of A and B without much trouble. Afterwards we may, if we please, continue to work out these values by means of formulæ similar to those already discussed in collating the groups; or we may content ourselves with assigning the limiting values of ϕ_x.

These values are, for the maximum,

$$\phi_x = S_x + \phi_y + \phi_z \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (37)$$

and for the minimum,

$$\phi_x = \left(V_x + V_y' + V_z'\right)\sqrt{\frac{T}{t}} \quad . \quad . \quad . \quad . \quad (38)$$

where V is equal to the sum of the values of M for the different groups of the given section; M, as before, being the number of lamps corresponding to the mean lighting current for the several groups. Indicating the different terms of M similarly to those of N previously given, we shall have

$$V = (M_1 + M_1' + M_1'' + M_2 + M_3 + M_3'' + M_4 + M_5) \quad . \quad . \quad (39)$$

The values of V corresponding to the *final* lighting current for the section are distinguished by a dash. Thus

$$V_x' = V_x + V_y' + V_z' \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (40)$$

When working in this way it will usually be desirable to retain the two limiting values of ϕ all through until the calculations are complete. We shall then be better able to decide how many and what different sizes of conductors should be actually laid down. In finally choosing a value between the limits, it must be remembered that we have uniformly assumed that the lamps are placed at the extremity of each section, and that we have thus introduced an error in excess. Other errors contained in the formulæ are (probably) mainly due to the exclusion of the "Irregular" lamps in certain places, and are thus errors of deficiency.

It will be obvious that any value of ϕ may be directly determined by treating the given section as though it was terminal, distributing all lamps supplied through it into their several groups, finding values for N and collating them as before. This process would usually involve much extra trouble, especially if there are many installations belonging to Group II. But for determining the dimensions of "feeders," and similar sections of any considerable length, it would probably be worth while to undertake the work.

Equation of Economy.

Returning now to the "equation of economy," it may conveniently be put into the form—

$$W = C_\theta \sqrt{\rho b} \quad . \quad . \quad . \quad . \quad . \quad . \quad (41)$$

Where C_θ is the final thermal current for the given section, W is the weight of the required conductor in pounds per unit length, ρ is the resistance of a conductor of unit length weighing one pound, and b is a term constant for any given installation within certain limits and depending only upon the financial data.

If we take 100 yards as our unit of length, and assume a working temperature of 25° C. and a conductivity of 95 per cent., we shall find that

$$\rho = 3^{\omega}.$$

(Strictly, $\rho = 3{\cdot}08^{\omega}$; but as neither temperature nor conductivity are known absolutely, we may as well take the whole number.)

*Paper read before the Society of Telegraph-Engineers and Electricians.

It may perhaps be thought that in (41) we should rather use the value $C_\theta \sqrt{\frac{T}{t}}$ as representing more nearly the actual current during the hours of working. We may certainly do this without error, for it will lead to the same value for W. This will be seen on examining the term b.

We have

$$b = \frac{{\cdot}00134\, z}{\beta(p + a)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (42)$$

Here z represents the cost of 1 E.H.P. per annum *developed continuously;* but if we increase C_θ to $C_\theta \sqrt{\frac{T}{t}}$ we shall have to take z for an average of t hours per day, consequently $\sqrt{b}$ becomes $\sqrt{b\frac{t}{T}}$, and in (41) W remains unaltered.

In estimating z we shall of course remember that the engines run q hours only per annum, and therefore we must find the cost of Q hours running at the particular rate per hour found for q hours.

In the above expression for b, β is that fraction of the first cost of the cable which is to be charged annually for interest and maintenance, p is the cost of copper per pound, and a represents an expression for the cost of insulation and protection *per pound of copper in the cable*, so far as this is not a constant sum. a may be of a form which does not admit of the direct determination of W in terms of C_θ, in which case we shall have to prepare tables of the values of C_θ for different values of W, and the value of b will then vary in different parts of the system.

Having found W—the weight of the required conductor per unit length—it is worth while to note that for a cylinder of copper we may put

$$d = 2\sqrt{\frac{W}{l}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (43)$$

where d is the diameter in inches, l the length in inches, and W the weight in pounds. In this case, the length being 100 yards, this reduces to

$$d = \frac{1}{30}\sqrt{W}.$$

In (43) the true log. of the coefficient is 0·300935. The formula is useful for finding the *effective* diameter of stranded cables.

Limiting Distance of Lamps.

Professor Forbes has shown that in any installation the distance of any given lamp from the nearest point of constant potential must not exceed a certain limit. Put this equal to L yards, and let e be the maximum variation of potential permissible, let r be the resistance per unit length of the cable, and let this unit length be l yards, then we must have

$$e = C r \frac{L}{l}$$

$$\therefore L = \frac{l e}{C r} \quad . \quad . \quad . \quad . \quad . \quad . \quad (44)$$

Now in this expresion for L we shall have $l e$ constant throughout the system, so that if L is to be constant we shall only require the condition $C \propto r^{-1}$. But this condition is fulfilled only when C is either equal to the thermal current or bears some constant ratio to it, and only then (as will presently appear) while the value of b is constant in the different parts of the system. Professor Forbes, in his recent Cantor lectures, seemed to imply that it would be sufficient to adjust the extreme variation of potential to the *average* current. But it seems doubtful whether this would be permissible in practice, because when there are any large installations in occasional use the maximum current is likely to be so much larger than the average. It appears to me, therefore, that in (44) C should be taken nearly, if not quite, for the maximum number of lamps which will ever probably be in use at one time. I should propose to obtain this maximum number by taking the total number hung, and deducting from this (1) say, one-half of the "Irregular" lamps, (2) all lamps in Group I$_A$,

Digitized by Google

(3) all lamps in Group I. which are extinguished before any of those in Group II. are lit. In this case the ratio $C\theta : C$ will not be constant throughout the system. Hence the values of L will also differ in different districts.

Let C_1 be the value of this maximum current in the first district, and indicating the particular values of the other terms in (44) by the same subscript, we have

$$r_1 = \frac{\rho}{W_1};$$

so that $L_1 = \frac{l e W_1}{C_1 \rho}$. Substituting for W_1 from (41),

we have $$L_1 = l e \frac{C\theta}{C_1} \sqrt{\frac{b}{\rho}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (45)$$

Now in this expression, whatever be the values of the units chosen, we shall have $(l \rho^{-\frac{1}{2}})$ constant, and (to give L_1 in yards) equal to 57. So that (45) becomes

$$L_1 = 57 \times \left(e b^{\frac{1}{2}} \frac{C\theta}{C_1} \right) \quad . \quad . \quad . \quad . \quad . \quad (46)$$

I may, perhaps, be permitted to mention, in conclusion, that I have elsewhere shown that the limits of L_1 are largely extended by the use of "multiple mains" when the relative dimensions of the external and intermediate mains are properly proportioned.

LARGE SECONDARY BATTERY PLANTS FOR COMMERCIAL DISTRIBUTION.*

We abstract the following from the American *Electrician*, to which Mr. E. P. Roberts, M.E., contributes the annexed description of a large secondary battery plant for general commercial distribution, at the same time quoting a description of "battery plant" previously given :—

"On each block—sometimes on every two blocks—is located a small portable house, in which are placed all the batteries furnishing light for said block. A partition divides it into two parts, one for the batteries and the other for the meters and switch-board. A plug switch is used in order that any combination may be readily effected. Cable connections permit coupling batteries together as desired. An extra battery is kept in each house for use in case extra light is required.

"The batteries are placed on string pieces 2in. by 4in. by 10ft.; each cell rests on four porcelain insulators, and the string pieces rest on Western Union insulators with pins set in cross pieces. Three sizes of batteries are used, 1, 2, and 3, with capacities of 20, 40, and 80-lamp hours respectively.

"Three charging circuits are used, two to private residences, where Nos. 1 and 2 batteries are used, requiring from 7 a.m. to 1 p.m. to charge them with a 10-ampere current, and one circuit to the business part of the city, where batteries are used. As these batteries are much larger, a longer time is required to charge them, and therefore they are charged from 7 a.m. until 3 p.m. by a 65-light dynamo. They are then connected by switch, as desired, for the night, in some cases three batteries being connected for quantity.

"At dark the charging circuit is looped in with the all-night outside arc circuit, and the charge thrown on about 20 meters, and by the connections for quantity controls about 50 batteries; thus they are left until daylight, when the arc circuit shuts down. By this means the batteries obtain considerable charge; they are then disconnected and charged separately during the day."

Directions for Erecting and Maintaining Storage Batteries.

A. Careful Insulation.

1st. Battery as a whole well insulated from the earth.

2nd. Each cell insulated from all others, excepting, of course, through the proper channel for the passage of current.

3rd. The positive and negative in each cell to be insulated from each other, except through the liquid. No connection by moisture on the upper edge of the containing box.

B. Regular Charge and Discharge.

1. Fill the battery every day.
2. Discharge the battery every day.
3. Never over charge.
4. Do not exhaust completely.

C. Do not expect batteries to take care of themselves.

1. Test electromotive force of each once a week with a voltmeter.
2. Test each cell with an acidometer once a month.
3. Each day see that each cell in each battery fills in the same time.
4. Keep plates covered with liquid.
5. Examine all connections frequently.

D. Keep extra cells complete and charged, with which to replace defective ones. Do not put uncharged plate or cell in battery in regular use.

E. Do not "box in" batteries. Give free circulation of air.

F. Keep all connections, switches, &c., as far as possible away from batteries.

G. Study the cause producing a new effect, and attend to details.

Remarks.

After considerable experience with storage batteries, my conclusion is that they have been both praised and belittled too much. That the service can be good is certain; but that for a closely settled district they are preferable to dynamos is not, according to my experience, correct.

Experience teaches the manufacturers many points in design and formation which greatly increase the reliability of secondary batteries. Experience in handling them teaches men many little matters which greatly assist in keeping the batteries in good condition.

My plan for our new station about to be erected will show, more forcibly than a lengthy disquisition, my ideas respecting secondary batteries in connection with stations for the distribution of electrical energy.

A building is to be erected near the business portion of the city, from which our arc lights will be supplied, and in which also will be placed dynamos for running the incandescent lights in the business district. Batteries will be used in portions distant from the station. These will be charged from 3 a.m. until 7 a.m. with a 15-ampere current. At the station will be several large batteries, which will be used for day lighting or in case of a breakdown.

AUTOMATIC BICHROMATE BATTERY.

This new arrangement of bichromate battery being of small dimensions, *i.e.*, 7½in. by 1¾in. by 8½in., and weight 6lb., may be said to be especially adapted for use in mines, &c., on account of its portability. One charge will, we are informed, light a 5 candle-power lamp for about two hours. The accompanying illustration will readily explain the special features of the battery. The electrodes are attached to an ebonite plate supported in position over the liquid by the upper edge of the containing case, within which is placed a more shallow case, constituting the liquid reservoir. The reservoir itself is free to move up and down without any possibility of disarrangement, and rests upon a small roller connected with a lever at the bottom of the case. By moving this latter the liquid reservoir is raised, and its contents "immerse" the electrodes. A ratchet arrangement prevents disconnection being made until the battery is out of use. By this arrangement, requiring the use of one hand only, an accurate regulation of the electrodes can be obtained; further, it is easy by raising or lowering the liquid reservoir from time to time, while the battery is in use, to displace the gas which gathers upon the surface of the electrodes, in consequence of their polarisation. The battery is easily recharged, the lid being opened; the ebonite plate referred to above as bearing the carbons and zincs can be lifted up, and the cells then be emptied and filled with bichromate solution. This battery, with surgical and other accessories, is manufactured by

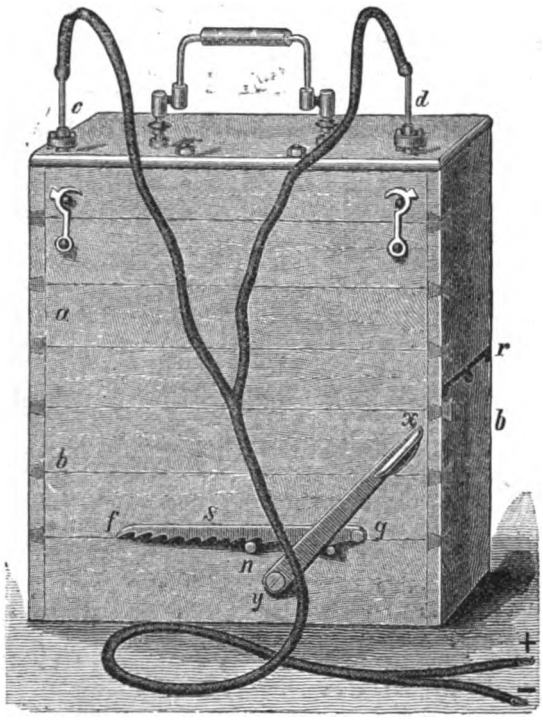
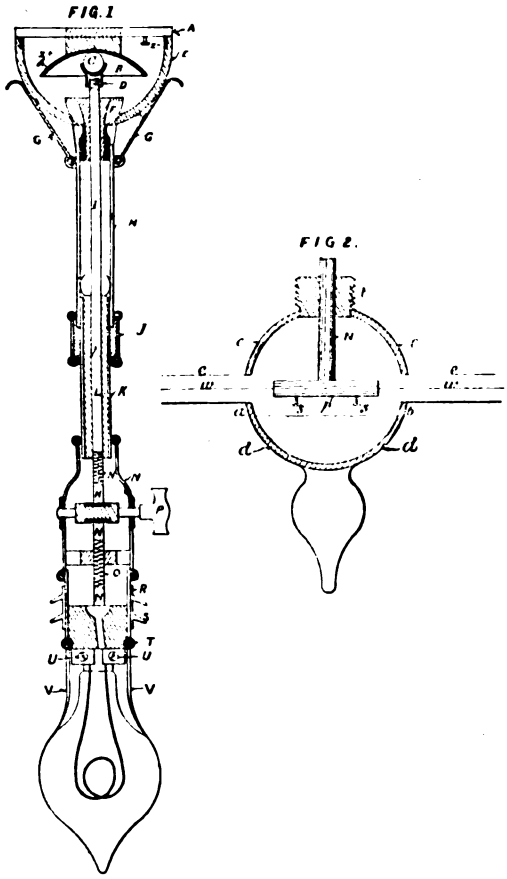
Messrs. Woodhouse and Rawson, 11, Queen Victoria-street, London, E.C.



The same firm also forward us a list of their primary batteries, which includes many of the late types of well-known elements.

GRUNDY AND READY'S TELESCOPIC PENDANT ELECTROLIER.

The electrolier is composed of two tubes, H and K, as in Fig. 1, sliding one within the other through a shifting box, J,



similar to a cork slide gas pendant. These tubes in connection with the ceiling plate A form one electrode, the other one being formed by the inverted cup B, which is insulated from A, the ball C and the rod I which slides in an inner tube L. The pendant swings and rotates in a sort of cup and ball joint at F, the contact between the outer tube and the cup E being assisted by the springs G G, and that between the inner rod I and the plate B by the spiral spring D under the cup and ball C. The switch P dispenses with the cost of wire labour, &c., in running a switch to a convenient place on the wall or other part of the room.

Any number of ceiling plates can be fixed in different rooms, and the wires being attached to them and not to the pendant itself it can be moved from room to room at will. If wanted for more than one light the attachment (Fig. 2) takes the place of the lamp holder, and any number of arms can be added or attached by any person in a few seconds. The stock size is capable of carrying six lamps at one ampere each, and yet is not too heavy looking for a single-light pendant. In this pendant there are no cords or pulleys to get out of order; the whole thing can be thoroughly relied upon, and a short circuit is impossible. It is fitted with a holder for plain lamps, but almost any centre contact fitting can be employed. The drawing is only intended to show the construction of the parts, but the desired ornamentation can be added at will.

LEGAL:

United Telephone Company (Limited) v. Bassano and another.

In the High Court of Justice (Chancery Division), before Mr. Justice North, this case came on for hearing this week. It was an action for an injunction and consequential relief in respect of the now well-known Edison patent for a telephonic transmitter, being part of the invention comprised in letters patent of July 30, 1877, granted to Mr. Thomas Alva Edison for "Improvements in instruments for controlling by sound the transmission of electric currents, and the reproduction of corresponding sounds at a distance." The patent, in respect of which three several disclaimers have been filed, is now the property of the plaintiffs, and has become a familiar subject of litigation in the courts. The present proceedings were restricted to the transmitting instrument as distinguished from the "receiver," and the alleged infringement consisted in the sale by Messrs. Bassano and Slater, the defendants, of telephones manufactured according to letters patent granted in 1883 to Messrs. Bassano Slater, and Hollins. The case was opened by the Attorney-General, who, with Mr. Aston, Q.C., Mr. Cozens Hardy, Q.C., Mr. Moulton, Q.C., and Mr. Micklem, appeared for the plaintiffs. Mr. Bigham, Q.C., Mr. Macrory, and Mr. Plumptre were for the defendants.

Sir Frederick Bramwell gave evidence for the plaintiffs. He had examined the various specifications and descriptions which were set up as anticipations of Edison's patent, and had come to the conclusion that it was a new thing at the date of Edison's patent to use anything that was caused to vibrate by sound valves, combined with a tension regulator in a closed circuit, so as to operate as a telephonic transmitter, except that there was a water telephone referred to in Morgan Brown's specification, and which formed the subject of Edison's sixth claim, now disclaimed. The water telephone could not present intimacy of surface-contact, which was of the essence of Edison's principle.

Cross-examined by Mr. BIGHAM, Q.C.: Edison's claims were originally 30 in number, but were now reduced to one. The meaning of that claim could only be ascertained by reading the general disclaiming words, and it was a combination claim, but he submitted that any question of opinion was for the Court. In Edison's patent transmitter the diaphragm was not within the resonant tube; it was at the end of it. The diaphragm of the defendants in the case against Harrison, Cox-Walker, and Co. was a sheet of platina foil acted on by the sound wave on the one side and itself acted on a large surface of pounded coke on the other side, and was by common consent itself the conductor of the current. That diaphragm (Hunnings) came in contact with the tension regulator, in effect performing the same functions as Edison's diaphragm. It intervened between the lips of the speaker and the regulator. In Edison's patent the diaphragm always comes between two parts of the same instrument. The board to which the instrument is attached at the back, supplemented by the enlargement at the termination of the resonant tube, is what corresponds in defendants' instruments to Edison's diaphragm, by receiving the sound waves and transmitting them to the tension regulator. The tension regulator in defendants' instrument is fastened to and is within the enlarged portion. The voice sets that portion into vibration, and those vibrations exert pressure on the tension regulator. The instrument will speak when used without the board at the back. The tension regulator unaccompanied by the diaphragm would be a commercial failure, because the sound waves act on the diaphragm, which in turn acts on the tension regulator; the combination is consequently essential. The addition of the board adds to the effect of the transmitter. Witness was not sure whether the tube was part of the diaphragm, or performed part of its functions. It must not be supposed that everything which performed the functions of a diaphragm was a diaphragm in the telephonic sense. To correctly designate a thing a diaphragm it was necessary to consider the context; a sheet of paper by

Digitized by Google

itself would not be described as a diaphragm, but when stretched over a pickle pot it was so; "it was a diaphragm when applied for diaphragmatic purposes." Witness did not profess to know how Edison's tension regulator works; the inventor probably does not know himself, but he had made it clear how to produce the desired result. The wooden portions of defendants' instrument constitute a diaphragm in the telephonic sense. It was not to be said that the principle was the same in Edison's transmitter and the defendants', but they were the same thing, although how the result was produced was actually unknown. The carbon pencils and the blocks in defendants' instrument were known as Hughes's microphone. It was not known whether the change in current depended on the change of the facets. In answer to the suggestion that compressibility was essential to all Edison's tension regulators, witness said that he had in former times reported to the owners of Bell's patent (the telephone receiver) to the contrary effect, and those persons had in consequence combined with the plaintiff company. He then explained the essential requirements of a tension regulator to be those of a semi-conductor made of such material as will enable it on the withdrawal of the pressure to return to its previous condition, and thus check the current which had been increased by the pressure.

Re-examined by Mr. MOULTON, Q.C.: The necessary requirements of the diaphragm were clearly described in Edison's specification. The variation of pressure on the carbon blocks in the defendants' patent must necessarily produce variation of pressure contact on the diaphragm.

Dr. Hopkinson was then examined by Mr. MOULTON: He had been well acquainted with Edison's patent for many years. The specification as amended fairly described the invention, and showed a variety of ways of carrying it out. The function of the diaphragm was to gather up the vibrations existing in the air when sound is transmitted, and then to transmit them through the tension regulator so as to cause variation in the resistance of the electrical circuit. That appeared clearly in the specification. He found a diaphragm and a tension regulator in defendants' instrument. The back board was a diaphragm, and so were the whole tube and the base. Edison contemplated in his patent the use of more than one diaphragm. He then described some experiments which he had made with the defendants' instrument, which proved that speaking into the base portion of the transmitter put it into vibration so that it would act on a tension regulator, and so again with the tube without the base, and the wooden board at the back. There were some seven or eight experiments in all which showed, in witness's opinion, that the wooden portion of defendants' transmitter operated as a diaphragm in the same sense as the diaphragm in Edison's invention.

Cross-examined by Mr. BIGHAM, Q.C.: Witness knew Reis's transmitter, which was prior to Edison's patent; the box and tube in that do not produce the effect of a diaphragm in the telephonic sense, although the voice would produce vibration throughout the instrument. It was very doubtful, however, if that vibration would produce any effect on the current of electricity. If an Edison tension-regulator were attached to the mouthpiece, the effect of a diaphragm would be produced. With regard to the experiments, his conclusion was that the wooden board at the back of defendants' transmitter contributed to the diaphragmatic action. In answer to a question as to the cause to which he should attribute the transmission of sound by transmitters of lead, thick wood, and putty, he said he should attribute that transmission of sound, if there was any, to the action of the sound waves upon the carbon pencils. If the defendants' carbon pencils were spoken upon without any wooden surrounding or back, a faint sound might be produced.

Re-examined by Mr. MOULTON, Q.C.: It was well known that sheet lead or even such a mixture as putty would take up acoustic vibrations, but imperfectly.

Sir William Thomson, examined by Mr. ASTON, Q.C.: He had read Edison's specification. His tension regulators as described were novel at the date of the patent. The term "diaphragm" was correctly used by him. It meant a "divider" or "separating thing." A separation was necessary to give rise to differences of the air pressure on the two sides of the divided medium. But for the separation the vibration of the air medium would be blocked. He should not consider that Edison exhausted the substances which could be used for diaphragms; light solid substances were best, such as wood, paper, parchment, aluminium, mica, brass, iron, but things very ill-suited for factors might do for diaphragms. Lead certainly would do, but not as well as wood. Water, mercury, and putty would also do. The question of adaptability of material to the vibrations of the sound waves was entirely one of degree. The essential requirements of a telephonic diaphragm were that it should act rapidly and be as clear and true as possible. The best materials were wood-membranes and elastic metals. He then described some experiments which he had made with the defendants' instrument. He had formed as the result an opinion that the board at the back of defendants' transmitting tube ought to be described as a diaphragm; it did in fact act as a diaphragm.

The case for the plaintiffs was concluded on Wednesday with the evidence of Mr. Imray. He stated that the invention in Edison's transmitter consisted of the combination of a diaphragm or tympan with an electric tension-regulator, that was to say, an imperfectly conducting body, which, when acted on by the diaphragm or tympan, occasions variations of resistance to the electricity passing through, the whole being included in a closed circuit, or complete line of conductor from one pole of a source of electricity, such as a battery, to the other. By a "diaphragm" or "tympan" the witness understood anything that would vibrate in accordance with sound pulses; it must necessarily obstruct those pulses, and therefore separate what was on one side of it from that which was on the other side. A piece of straight-grained wood formed the best diaphragm. It made no difference whether the diaphragm was between the wire and the tension-regulator or *vice versâ*. The witness explained in detail the functions of the diaphragm, and demonstrated the manner in which, in his opinion, the defendants' transmitter infringed the plaintiffs' patent, the diaphragm in their case being found in the sides of the speaking trumpet and its base, as well as in the back board to which it was fastened. Some practical experiments were then carried out, an operator speaking to his lordship through the defendants' transmitter, the voice being directed first directly in front of the instrument, then at the back, and at the side of the tube; then into the trumpet alone detached from the wooden back; then further with the carbon pencils alone fixed on the back board, and without the trumpet; with the carbon pencils suspended in the air by two silk fibres, and connected by two pieces of brass wire; and, lastly, with the board brought up to and again removed from the back of the trumpet during the speaking.

Mr. BIGHAM, Q.C., then opened the case for the defendants by stating that there were three questions to be tried, namely, whether the defendants had infringed the plaintiffs' patent by using a diaphragm within the specification; whether they had used a diaphragm in combination with tension-regulators within the specification; and, thirdly, whether the tension-regulators, as combined with the diaphragm were commercially useful so as to render the patent valid. He then proceeded to contend that the defendants did not use a diaphragm as described or contemplated by Edison, and undertook to demonstrate by experiments that the back board to defendants' instrument did not perform the functions of Edison's diaphragm, and the instrument would work as well without it as with it. Then as to the tension regulators, they were no infringements of Edison's invention.

The hearing of this case was continued on Thursday, and the judgment will be given in our next issue.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The twenty-sixth half yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, the 16th inst., at the City Terminus Hotel, Cannon-street, John Pender, Esq., M.P., presiding.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN stated that the revenue for the six months ended March, 1885, had been £371,682, being an increase of £26,526 as compared with the corresponding period of 1884. This increase had no doubt been owing to the large number of Press and Government telegrams sent in consequence of the military operations in Egypt and India, and of the war between France and China. The total working expenses had been £91,599, or an increase of £1,117 as compared with the corresponding period of 1884. The general expenses in London had been £1,085 less, but the working expenses at the stations had been £2,959 more. They had opened out four new stations in the half year, namely, at Perim, Piræus, Patras, and Katacolo. There was also a full six months' charge for working the Suakim station against only four months in the same period of 1884. The patent rights of certain inventions of Sir William Thomson—who for the last fourteen years had been receiving a very handsome income from them—were about to expire, if they had not already expired, and that would cause a reduction of £3,000 per annum. In making that statement, however, he ought to say what a great debt they were under—indeed, the whole world was—to Sir William Thomson for these inventions, which had enabled submarine telegraphy to be carried to a point which he believed would not otherwise have been possible. The repairs and renewals of cables had cost £44,815, against £37,113, being an increase of £7,702. The question of repairs had always been an important one, and as their cables were naturally growing older, it must become still more serious, but they had tried in the conduct of their business to maintain their system in as efficient a condition as possible. They had duplicated a very large extent of their system, and they had done a good deal of that duplication and all the repairs out of revenue. They therefore had a very efficient system, but one which required constant care and attention, and it was necessary to have their ships placed at the proper stations, so that they might use them immediately if necessary to effect any repairs. The work done by their ships in the half year had been very considerable. After charging all expenses, including income tax, providing for interest on debentures, debenture stock, and preference shares they were enabled to pay a dividend and bonus of 6 per cent. per annum, and to carry £100,000 to the reserve fund, against £65,000 in the corresponding period of 1884. On the other hand they had written off that fund the discount on the issue of 4 per cent. mortgage debenture stock. Their general reserve fund now amounted to £397,272, and the total reserve funds, including the Sardinian cable and other special reserves, was £431,705. He might state that in 1877 they took £100,000 from the reserve fund in reduction of the cost of new cables; in 1878 they took £13,997 in reduction of the cost of renewals; in 1884 they took £300,000 towards the cost of new cables; and in 1885 they took £28,105 discount on the issue of 4 per cent. debenture stock, or a total of £442,102. Therefore, had the money been kept in the reserve fund, that fund would now amount to nearly £900,000 instead of £431,705. They thought, however, that they had done wisely in the course they had pursued, as it had enabled them rather to increase their traffic, and therefore maintain their dividends. During active times it was absolutely necessary that they should maintain their system in a thoroughly efficient manner. Two or three months ago there was an important scare, which was supposed to have subsided; but on the previous day there was another scare, which had a very serious effect on stocks in the London market. They must have their system in such a condition as to enable them to be

Digitized by Google

prepared for scares, come when they might, so as to meet the requirements of the Government, and the telegraphing public. Gibraltar and Malta were two very important strongholds in the Mediterranean, and they thought they ought to have that system especially thoroughly efficient. A considerable amount of the £100,000 now put to the reserve fund had perhaps come out of scares which had occurred rather than from out of legitimate traffic. What they intended now to do was to triplicate the line from the Land's End to Malta, and having done that they would consider the shareholders in a most sound and safe position. He believed this would cost some £300,000; but he believed they would be able to meet that charge partly out of reserves and partly out of other sources in a way which would make their present position more stable. This work they would see was all the more important when he mentioned the breakages which now existed. The following were the cables interrupted:—The Direct Porthcurnow-Lisbon, the Gibraltar-Lisbon, the Suez-Suakim, the Suakim-Perim, and the Bombay-Aden No. 1. They had the thing thoroughly in hand, however, and probably in a week hence they would be in working order again. Meantime, by the arrangements they had made they would be able to earn their income pretty much as if these breakages had not happened. They had occurred since the issue of the report. They had just made an arrangement with the Greek Government, who were very much advanced in their desires for the establishment of submarine telegraphy. The arrangement was for thirty-four years, during which they would receive a subsidy of £6,500 per annum, upon an expenditure of 447 miles of cable.

A SHAREHOLDER: How much money would that be?

The CHAIRMAN: About £60,000 or £70,000. Continuing, he stated that they were now dealing with Turkey, and probably by the time he next addressed them they would be able to say that they had made arrangements for extensions to the Arabian ports of the Red Sea. One would suppose, from the recent craze on the part of Germany and France to possess colonies, that the West Coast of Africa was a sort of Paradise; and it was notorious that the Portuguese Government had invited tenders for a cable to the West Coast of Africa. England had perhaps more important interests there than any other country, and had therefore been obliged to follow suit. He hoped they would be able to report shortly that they had made an arrangement with the British Government in regard to cables in this direction. It was a curious fact that ever since the cable between Zanzibar and Mozambique had been established it had been interrupted every year at much about the same time and place. It appeared that there were two great rivers that ran into the sea at that particular point, and they had now discovered that the cause of the interruption was the great rush of water undermining the land where the cable lay at the bottom of the sea. This cable was, therefore, now being duplicated, and it would cost the South African Company—in which this Company were large shareholders — about £120,000, which would come out of that Company's reserve fund. Next month the telegraph conference would be held in Berlin, and the question of submarine and land telegraphs would then be discussed by the delegates of all the important nations of the world, by whom they had been treated, on the whole, in a fair and reasonable manner, though they were not yet admitted to their councils. There was, however, a feeling abroad now—particularly in Germany, headed by the Telegraph Minister there—that submarine telegraphs should be more or less subordinated to the views and actions and policy of the land lines, and the wish of that gentleman was that there should be a system and a tariff throughout Europe, which would certainly not suit the Company. The cost of a land line and of a submarine line had, however, to be considered, and they maintained that, grand as the land line system was, it did not connect with the world at large, which the submarine cables did. The owners of the latter were therefore, entitled to the highest consideration, and he hoped they would be able to succeed in impressing their views on the delegates at the conference. The system of submarine telegraphy had done a great deal in revolutionising the world, and he hoped they would still further revolutionise the world for good. He concluded by moving the following resolution:—

"That the printed report and accounts of the Directors to 31st March, "1885, submitted to this meeting, be and they are hereby received and "adopted; that a dividend on the Preference shares of the Company to "the 30th June, 1885, at the rate of 6 per cent. per annum be paid, less "income tax; and that, in accordance with the Directors' recommenda- "tion, a dividend be and is now declared of 2s. 6d. per share with a bonus "of 1s. per share, both free of income tax, on the Ordinary shares of the "Company, making, with previous payments by way of dividend on "account, a total payment of 6 per cent. on these shares for the year "ended 31st March, 1885."

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion, which was carried unanimously, without discussion, and a vote of thanks to the Chairman and Directors brought the proceedings to a close.

[A full report of this meeting will appear in our next issue.]

The Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 30th June last, to be presented to the proprietors at the sixteenth ordinary general meeting, to be held at the Cannon-street Hotel, on Friday, the 24th inst., at 2 p.m.

With this report the Directors submit the usual statements of account for the half year ending 30th June, 1885, which, with the half year's accounts to 31st December last, presented at the ordinary general meeting on the 5th February last, show the financial result of the eighth year's working of the Company. The revenue for the half year, after deducting out-payments, amounted to £36,106. 1s. 1d. against £68,573. 8s. 11d. (after similar deductions) for the corresponding period of 1884, being a difference of £32,467. 7s. 10d. against the half year under review, owing to the operation of the reduced tariff mentioned in the last report. The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cable, amounted to £17,206. 15s. 11d., leaving a balance of £18,899. 5s. 2d. as the net profit of the half year, making, with £17,251. 2s. 11d. brought forward from the previous half year, a total of £36,150. 8s. 1d. Two quarterly interim dividends of 1½ per cent each, and one quarterly dividend of ¾ per cent., together amounting to £39,461. 10s., have been declared and paid at the usual times during the financial year, and a final dividend of 3s. per share is now proposed, making, with the three interim dividends, 4 per cent. for the year, being a total distribution of £48,568. The appropriation of the above balance of £36,150. 8s. 1d. on the revenue account is thus shown:—

Interim dividend for quarter ending 31st March, 1885	£9,106 10 0
Final dividend now proposed	9,106 10 0
Carried to reserve fund (thereby increasing it to £310,000)..	7,203 13 6
Carried forward to next account.....	10,733 14 7
	£36,150 8 1

A break occurred in our main section of cable on the 27th January last, and was promptly repaired on the 17th February; the cost of the repair, £2,857. 18s. 9d., has been charged against the reserve fund. Our short section of cable is at present interrupted, but the interruption does not affect the working of the traffic, which passes by the alternative land line between Torbay and New York. The repair will be made as soon as possible. Pursuant to the provisions of the Articles of Association two of the Directors, viz.:—The Lord Hawke and Sir Henry Keppel, retire by rotation, and being eligible, offer themselves for re-election. Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

NOTES.

NOTICE OF REPAIR.—The cables of the Western Union Telegraph Company are now repaired.

NOTICE OF INTERRUPTION.—The cables between Suez and Suakim and between Perim and Suakim are interrupted.

BARCELONA.—The Barcelona Exhibition will be inaugurated in the month of September, 1887, and will remain open until April, 1888.

THE MILDE TELEPHONE.—In a recent issue of our contemporary *L'Electricien* an interesting article is given upon the Mildé Telephone.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 17th inst. were £2,997.

THE TELEGRAPHS BILL.—The House will probably sit to-morrow (Saturday), in order to forward the Telegraphs Bill and other measures.

AN AERIAL ELECTRIC RAILWAY.—It is proposed to construct a small aerial railroad in Paris, on the American model, the motive power being supplied by electricity.

A NEW CONTEMPORARY.—We have received the first issue of the *Revue Internationale de L'Electricite et de les Applications*. We wish our young contemporary every success.

APPOINTMENT.—We understand that Mr. Melhuish, late of Siemens Brothers, has been appointed resident engineer to the Imperial and Continental Gas Association of Vienna.

THE ELECTRIC LIGHT IN QUEENSLAND, AUSTRALIA.—A preliminary trial of the electric light, which has recently been made in the Parliament Buildings, gave great satisfaction.

SAW-DUST FUEL.—One of the electric lighting companies in America now uses saw-dust for fuel. It finds this fuel, we are informed, more economical than screenings for making steam.

VOLK'S ELECTRIC RAILWAY.—The Town Council of Brighton, at a recent sitting, decided to allow the electric railway to remain on the beach on terms more favourable to the Corporation.

GETTING ROUND THE CLIMATE.—In Algiers they are making use of the electric light for harvest operations at night. The climate is such that no European can work during the day time.

THE PERSIAN TELEGRAPHS.—A telegram from Teheran says that telegraphic communication between Teheran and Meshed is very unsatisfactory. The line is working badly, and frequently breaks.

BOOKS RECEIVED.—"Electric Lighting," "The Catalogue of the Kinetic Engineering Company," "The National Telephone Company (Limited) List of Subscribers in the Edinburgh District for July."

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th July are £2,529, as compared with £3,141 in the corresponding period of 1884.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending the 17th inst. were £2,287, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

A NEW LIGHTNING CONDUCTOR.—Mr. Hubbell, of Washington, has conducted some successful experiments with a new lightning conductor, which has been designed with a view to the efficient protection of the immense reservoirs of oil which are exposed to the atmosphere in the vicinity of that city.

THE ELECTRIC LIGHT IN PAISLEY.—The Edison and Swan Company are now working on another installation of about 800 lamps for Messrs. J. and P. Coats, Paisley. This is the third installation for the same firm secured by the Scottish branch of that company before it was broken up in May last.

A LARGE GALVANOMETER.—There has just been completed at Cornell University the largest galvanometer in the world. It has been built under the direction of Prof. William A. Anthony, of the department of physics, and over a year was spent in its construction. It has four circles, each two metres in diameter.

LOWESTOFT.—At a recent meeting of the commissioners of this town a communication was received from Messrs. Laing, Wharton, and Down, electrical engineers, London, offering to treat with the commissioners for introducing into the town their system of arc lighting, which had been received with so much favour in the United States and at the Inventions Exhibition.

THE ELECTRIC LIGHT IN MILAN. — The work of installing the electric light in the offices of the President of the Giunta and the various other offices of the municipality of Milan is being proceeded with. The contract, which is for five years, and which comes into operation on the 1st of next September, has been obtained by the Società Generale di Elettricità.

LITERARY ANNOUNCEMENT.—We understand that Mr. Alexander Watt has been for many months engaged in writing a comprehensive practical treatise on the electro deposition of metals, including the electrolytic refining of copper and other metals and treatment of ores. The work, being now complete, will shortly be in the hands of the public. The publishers will be Messrs. Crosby Lockwood and Co.

FIRE IN AN ELECTRIC SHOP.—At a quarter to 1 o'clock on Wednesday morning a fire broke out in one of the lockers in the electric shop in the Portsmouth Government dockyard, supposed to have been caused by the spontaneous ignition of some waste which had been stored there. The building is constructed of corrugated iron, and the fire being confined to the lockers little damage was done.

THE ELECTRIC LIGHT IN VIENNA.—The Imperial Gas Association in Vienna have, we are informed, decided upon the establishment of a central electric lighting station at which sufficient current will be generated to aliment 12,000 sixteen candle-power incandescent lamps. The installation at the central station will consist of four steam engines of 200 horse-power, four dynamos and 9,600 accumulators.

NEW ELECTRIC LAUNCH.—The Electrical Power Storage Company are building an electric launch for the Duke of Bedford, to be used in connection with his steam yacht, the "Northumbria." The launch will be 28ft. long, and will be suspended from the davits, the accumulators being used in connection with the existing electric lighting of the yacht when they are not required for the propelling of the launch.

HOLIDAY MAKING. — On Saturday last the officials and *employés* in connection with the establishment of Messrs. Walter T. Glover and Co., of Salford, to the number of 121, paid a visit to Blackpool, where they were indulged in a round of gaieties. Free tickets of admission to the Winter Gardens

Digitized by Google

and the Aquarium, as well as an excellent breakfast and dinner, were provided by the firm, who also defrayed the railway and other charges incidental upon the journey.

THE ALBERT PALACE, BATTERSEA.—The installation at the Albert Palace, Battersea, comprises nineteen 2,000 candle-power Brush arc lamps distributed in the gardens and nineteen Victoria incandescents. The current is supplied by two Brush dynamos of the old type driven by a 12 horse-power semi-fixed Robey engine. We are informed that it is the intention of the management to add to this installation at an early date a further number of 650 incandescent lamps.

A SERIOUS FIRE.—A fire which broke out on the night of the 16th inst. at Washington destroyed the building occupied by the offices of the *Washington Post*, the *Washington National Republican*, the *Washington Critic*, and the *Sunday Gazette*, and by those of an electric light company, besides destroying property valued at 150,000 dols. Every lamp connected with the electric light company's office was extinguished, leaving some portions of the city in comparative darkness.

FATAL ACCIDENT.—On the afternoon of 30th June, in West Indianapolis, a foolish person, for a trifling wager, climbed to the top of an electric light tower, 120ft. high. He attempted to descend by means of a guy rope, but his grip on the rope was lax and he descended at such speed that the friction caused him to relax his grasp, when he fell to the ground, 70ft. In falling his body struck some telephone wires, turning him head downward, and he fell on his head and shoulders, fatally injuring himself.

DOMESTIC LIGHTING IN BELGIUM.—*La Chronique des Travaux Publics*, in a recent issue, gives an account of an installation which has been put down in the Château du Rond-chêne, the residence of M. Montefiore-Levi, who is said to be an ardent promoter of electrical science. This comprises an 18 horse-power engine, driving a Victoria and a Gramme dynamo. These supply current to 300 20 candle-power incandescent lamps, which light the whole of the rooms, staircases, corridors, and offices of the château.

TELEGRAPHIC COMMUNICATION WITH BARRA.—Telegraphic communication was opened to Barra about the beginning of last September, but it seems that during the herring fishing one wire along the whole system is wholly inadequate for the business of the place. The result is that a special wire for Barra is now being erected from Lochbeisdale to Lochmaddy, and possibly to Stornoway; so that in future messages can be sent direct to these places without interfering with the business of the intermediate telegraph stations.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of this company, held on the 21st inst., it was resolved, "After placing the sum of £12,500 to the Renewal Fund, making £50,000 for the half year, to declare an interim dividend for the quarter ending 30th June, 1885, of 6s. per cent. on the Ordinary stock, and 12s. per cent. on the Preferred stock, less income tax, payable on the 1st August to the shareholders registered on the books of the company on the 17th July, 1885."

AN ANTI-HOAX FIRE ALARM.—An ingenious individual, Mr. E. Jungerman, of Gettyburg, Pa., has invented a new system of fire alarm apparatus, which, if adopted, will put a stop to the little games of certain misguided people who think it a good joke to raise fury in the breasts of too patient firemen. This device compels the sender to the alarm to remain in a box until the arrival of the person or persons summoned. A very good idea we think, for no charitable person would surely object to be boxed up, in so good a cause, for a few seconds.

ELECTRIC LIGHTING OF TRAINS.—On the occasion of the visit of H.R.H. the Prince of Wales to Preston, Lancashire, the Royal train was lighted by electricity. Two head-lights were used, each of 50 candle-power, and forty 20 candle-power lamps were distributed in the saloons, &c. These were the Woodhouse and Rawson 40-volt pattern, and were supplied from E.P.S. accumulators. The fittings and electroliers, we are informed, were of the most elaborate description. H.R.H. the Prince, the Duke of Sutherland, and others expressed great satisfaction with the light.

LONG DISTANCE TELEPHONY IN AUSTRALIA.—In connection with telephonic communication, a very interesting series of experiments has been carried out lately by Mr. Parsons, the Telegraph Station Master at Albury, with Melbourne and Sydney. An extra thick wire, which had been laid down along the distance between the two capital cities, was used, and between Melbourne and Albury the result was most satisfactory. Voice-speaking at Melbourne, 187 miles away, was clearly and distinctly heard at Albury, the identity of the speaker being easily recognisable.

ASSOCIATION FRANCAIS POUR L'AVANCEMENT DES SCIENCES.—The next session of this association *(Congrès de Grenoble)* will endure from the 12th until the 20th of August, 1885, inclusive. Amongst the questions which will be treated in the physical and chemical sciences group we notice the following:—A new method for the determination of magnetic movements, by M. J. B. Baille; the application of condensers to electro-physiology and electro-therapia, by Dr. Baudel; a new induction coil, by Dr. Dagrève; measurement of electric resistances, by Prof. Hurion; India rubber, by M. Roussel, &c.

ICEBERGS IN FOG.—Some recent experiments show that echoes may be plainly heard at sea, even when the object sending back the sound is a mile away from the source of the sound. It is suggested, therefore, that icebergs might be detected at sea and avoided if shots were fired periodically from the bow of a steamer or other vessel. Mr. Della Torre, who originated this method, claims that a steam whistle or siren, combined with a projecting apparatus like a speaking-tube, will serve as efficiently as a gun. Prof. A. G. Bell has taken great interest in the method, and has conducted the experiments establishing its feasibility.

THE ELECTRIC LIGHT AND PHOTOGRAPHY.—Some experiments took place at Woolwich Arsenal on Saturday with a view of testing the practicability of photographing the interior of guns by means of the electric light, so as to detect flaws during their manufacture or cracks after firing. Two 8in. muzzle-loading guns formed the subject of the test. The light was introduced a short distance within the muzzle, and reflected down the bore by means of a mirror, the photograph being taken from the breech end. The light produced by a dynamo was not quite so steady as that from a primary battery or accumulators, but both gave good results.

ELECTRICITY AND WARFARE.—Some interesting experiments were carried out during the course of last month at Schœneberg, near Berlin, with a view to the application of the electric light, in conjunction with captive balloons, to the purposes of military reconnaissances. A balloon, provided with an arc lamp, was elevated to a height of about 200 feet, and upon the light being projected by means of a powerful reflector sufficiently satisfactory observations of the country in the immediate vicinity were made. The lamp was supplied with current by a Siemens dynamo; and telephonic communi-

Digitized by Google

cation was maintained between the car of the balloon and the earth.

ELECTRIC SIGNALLING BALLOON.—On Monday evening last a number of gentlemen assembled in the gardens of the Albert Palace at Battersea to witness a trial of a new system of electric signalling from balloons, devised by Mr. Eric S. Bruce. The novel feature of this invention is the introduction of incandescent lamps in the body of the balloon. On the occasion referred to, six 16 candle-power Swan-Edison lamps, fed by twenty-four E.P.S. accumulators, were placed inside a captive balloon of translucent material, and after it had attained to a height of about 200 feet from the ground, signals by means of the Morse code were conveyed at a speed of four or five words per minute to a supposed friendly force at a distance of some ten or fifteen miles from the scene of operations. The invention promises to be a valuable one.

TELEPHONIC COMMUNICATION AT THE MARRIAGE OF PRINCESS BEATRICE.—In order that direct telegraphic communication may be had with Her Majesty's royal yachts in Cowes Bay, to enable them to immediately carry out sudden orders from Osborne House a telephone wire has been recently laid down from the billiard room in the royal residence to the royal landing stage, East Cowes, off which lie at anchor the "Alberta," "Victoria and Albert," and other royal yachts. The telephone was first used on Wednesday morning last, when Her Majesty inspected the Camel Corps, and has been found to work admirably, and to be of the greatest possible use. The telephonic appliances consist of Johnson's patent transmitter and Bell's patent telephone, and have been supplied by Messrs. Tasker, Sons, and Co., of Sheffield.

ELECTRIC LIGHTING IN DYE HOUSES.—Owing to the prevalence of steam in dye houses, some difficulty has been experienced in adapting the electric light to the peculiar conditions which are required. This difficulty, however, seems to have been overcome, and, considering how necessary it is that the dyer should be able readily to distinguish the various colours he has in hand, it is not an unimportant achievement. Messrs. J. Bannister and Sons, dyers, of Leeds, have recently introduced the electric light into their works, and have obtained a satisfactory result. The lamps used are the Pilsen arc of 1,000 candle-power each, and they are run from a Phœnix dynamo, made by Messrs. Paterson and Cooper, at their steam factory, Pownall-road, Dalston. The installation was carried out by their representative, Mr. Wilson Woodhead, Royal Exchange, Leeds.

THE "CASSEL" PROCESS.—On Friday last experiments on a large scale were made at the works of the Cassel Company in Verulam-street, London, to demonstrate the efficacy of their process for the treatment of refractory gold and other ores. Amongst those present were Mr. J. E. Spagnoletti, President of the Society of Telegraph-Engineers and Electricians; Professor George Forbes; Dr. Hugo Miller, F.R.S.; Mr. Warren De La Rue, F.R.S.; Sir Hussey Vivian; Mr. J. Arthur Phillips, F.R.S.; Sir Hugh Low; Sir Charles Tennant, Bart., Chairman of the Cassel Company; Col. Sir Francis Bolton, and others. The point of interest in this process is the introduction of lime to effect the precipitation of the iron in solution. The experiments, which were conducted by Mr. Henry R. Cassel, the inventor, Dr. Henry Liepmann, F.C.S., and Dr. Rowland J. Atcherley, F.C.S., gave great satisfaction.

THE MECHANICAL TELEPHONE.—Under the designation of "The Mechanical Telephone," says a non-technical contemporary, a new instrument has just been brought to this country from America, and was tested in London last week. This telephone does not require electricity, but, as its name implies, is purely mechanical. Its construction is simple, and consists of a diaphragm or sounding board made of strips of willow wood closely interwoven together and varnished. This wood is found to possess a high degree of sensibility to sound vibrations. In the centre of the diaphragm is fixed a disc of metal from which the communicating wire passes to any point desired up to two miles. The instrument, being enclosed in a small wooden case, can be easily fixed, and remains ready for use, requiring no attention of any sort. Various methods were adopted to try the utility of the instrument, and in all cases it fully met the demands made upon it.

THE EARTHQUAKES.—A Reuter's telegram, dated Bombay, July 18, says that a severe shock of earthquake occurred on the day previous at Murree, but without causing any serious damage. No one was injured. Shocks of earthquake are also reported from other parts of the Punjaub. Another telegram from Simla, dated July 17, announces that during the last few days there has been a recurrence of earthquake shocks in Cashmere. The total loss of life by the recent earthquakes in Cashmere is officially estimated at 3,081. Upwards of 25,000 sheep and goats and 8,000 cattle were killed, and 70,000 houses were laid in ruins. Subsequent to the above twelve shocks of earthquake, one of which was very severe, were felt in Cashmere. This was on the 16th inst. A telegram from Teneriffe announces that a shock of earthquake was felt there on the morning of the 22nd instant. No details had been received up to the hour of our going to press.

THE PROPOSED ALTERNATIVE CABLE TO THE CAPE.—On June 18, at Cape Town, Mr. Sprigg (on behalf of Mr. Upington) moved that the House go into committee to consider the following resolution:—"That the Government be authorised to enter into negotiations with the India Rubber and Gutta Percha Company, of Silvertown, or other suitable company, for the purpose of securing an alternative line of cable communication between the colony and England, *viâ* the West Coast of Africa, provided the amount of subsidy payable annually does not exceed the sum of £——." Mr. Sprigg said that the honourable Attorney-General would be able to explain to the committee, when he was in the House, what prospect there was of obtaining an alternative cable. He moved that the House go into committee on June 22, which was agreed to. It would seem, however, that this had not been done, owing, perhaps, to the long debates which had taken place upon the estimates.

A REMARKABLE PLANT.—A recent German publication contains a description of a new electric plant that has been christened Phytolacca electrica, which possesses strongly marked electro-magnetic properties. In breaking a twig the hand receives a shock that resembles the sensation produced by an induction coil. Experiments made on this plant showed that a small compass was affected by it at a distance of about 20ft. On a near approach the needle vibrated, and finally began to revolve quite rapidly. The phenomena was repeated in reverse order on receding from the plant. The energy of the influence varied with the time of day, being strongest at about two o'clock p.m., and becoming almost nothing during the night. It was also greatly increased in stormy weather; and when it rains the plant seems to wither. It is said that no birds or insects are ever seen on or about this plant. The soil where it grew contained no magnetic metal like iron, cobalt, or nickel, and it is evident the plant itself possesssed this electrical property.

THE ELECTRIC LIGHT IN TURIN.—The installations which are to be put down in Turin by the National Company for the

Digitized by Google

distribution of electricity by secondary generators and by the Società Italiana del Gaz will, as far as the lamps are concerned, be located as follows: Piazza Vittorio: exterior, 12 arc lamps of 1,000 candle-power, and 50 incandescent lamps of 50 candle-power each in the doorways; Via Po: 10 arc lamps of 800 candle-power, and 50 incandescents of 50 candle-power in the doorways; Piazza Castello: 4 arc lamps at the corners of the Palazzo Madama, of 5,000 candle-power each, and 30 incandescent lamps of 50 candle-power in the doorways; Galleria Subalpina: 2 arcs of 800 candle-power each; Via Roma: 40 incandescent lamps of 50 candle-power; Piazza San Carlo: exterior, six 800 candle-power arcs, and 10 incandescent lamps of 50 candle-power in the doorways; Via Garibaldi: 12 arc lamps of 800 candle-power at the corners of the streets; Piazza dello Statuto: 8 arcs of 800 candle-power, and 30 incandescents as before; Piazza del Palazzo di Citta: 2 arc lamps of the same kind as the preceding, and 5 incandescents in the doorways.

New Telegraphic Cable to Shetland.—On Tuesday last week, as notified in our last issue, operations in connection with the new telegraphic cable from Aberdeen to Shetland were successfully completed, and communication between these places may now be said to be satisfactorily established. Meanwhile, the work is being conducted by the single process, but it is expected that the duplex principle will shortly be introduced. The line was decided on by the Department after careful investigation during the winter, and its object, as mentioned in our last issue, is to facilitate the business of the herring trade, which is now commencing for the season all along the north-east coast. The cable ship "Monarch" has been employed in the work for the past three weeks. The total length of the line is about 300 miles. The advantage of the new arrangement is that direct communication can now be had between Shetland and London with only one retransmission, namely, at Aberdeen. There were formly three transmissions—Edinburgh, Inverness, and Wick—and the great benefit of the telegraphic facilities now afforded is obvious.

The Electric Light in Brooklyn, U.S.A.—The Municipal Electric Light Company, of Brooklyn, opened a new station recently at 306, Penn-street, and also lighted a large portion of the Eastern District for the first time under the provisional contract with the city. The lighting was, we are informed, admirable. The new station is of brick and substantially built. The dimensions of the building are 60ft. by 100ft. In the basement in front on one side are three furnaces and boilers. These are each 8ft. by 16ft., and each boiler contains eighty-four 3½ inch tubes. On the same side of the building on the ground floor are five Buckeye engines. Four of these are 6in. by 14in. and have a capacity of 60 horse-power, and the other is 11 × 16in., and has a capacity of 150 horse-power. Connected with these by belts are 10 dynamos. The total capacity of the present machinery is about 400 lamps of 1,200 candle-power each. The engines are set upon solid masonry, and there is no vibration when all the machinery is in motion. Only one side of the building is now occupied, making it possible to double the capacity of the works.

Lamp Shades.—The subject of the degree in which lamp shades serve to abstract light, or to increase illumination at certain points, has been taken up by Prof. H. L. Cohn, in Germany, who recently described a long series of determinations of the relative values of various forms of lamp shades. The method pursued was to measure the brightness of white paper lying on a table over which the source of artificial light was suspended at a given distance, by means of a Weber photometer. As one would anticipate, the general effect of a shade is to increase very greatly the illumination immediately under the light, and not to modify it notably at an angular distance greater than forty-five degrees from this region. Taking as a measure of the value of the illumination the number of lines which can be read from a newspaper in a minute, and as the unit of illumination that of a normal candle at a perpendicular distance of a metre from the paper, he finds that the best illumination is not less than fifty such units. Since even a fifth of this illumination is very rarely secured, except immediately under a lamp provided with a good shade, he emphasizes the conclusion that few persons work in a satisfactory light.

The Post Office Telegraphs.—According to the Postmaster-General's annual report, the telegraph business of the country shows but little development, and an increase of only 435,000 messages in the year cannot be regarded as satisfactory. The yearly increase has, owing, no doubt, to the stagnation of trade, the competition of the telephones, and the rapidity of the letter post, been steadily diminishing during the last five years. The expenditure has, however, largely increased, and it will be noticed that last year it exceeded the revenue by about £36,000, and that for two years no contribution has been made towards the payment of the interest, amounting to £326,417 a year on the capital invested. The department has at present twenty-seven telephone exchanges open in various country towns, with a list of 1,141 subscribers paying a total of £22,600 a year, but by far the greater part of the telephone exchange business of the country continues to be conducted by private companies, who now obtain licenses from the department on the very liberal terms laid down in August, 1884. The royalties paid by companies amounted to only £19,370 in the year. The full effect of the telephonic competition with the telegraphs remains to be seen, but the Postmaster-General cannot doubt that the telegraph revenue has been and will be adversely affected.

Electric Light at the Mansion House.—Mr. G. Offor has written to the *City Press* as follows:—"'Another failure of the electric light at the Mansion House' is calculated to prejudice the public unless it is explained that such failures can be absolutely prevented by the use of storage batteries, without which no system of incandescent lighting is perfect. All installations of importance are now being made with the aid of storage batteries. Among those successfully working in the City, I need only refer to the Bank of England, Peninsular and Oriental Steam Navigation Company, Messrs. F. Huth and Co., Messrs. A. Gibbs and Sons, Messrs. Spink and Son, Messrs. Foster and Braithwaite, Messrs. Johnson, Matthey, and Co., the Falstaff Restaurant, the Consolidated Electric Company's offices and factory. This company tendered to light the Mansion House with 520 lamps of 20 candle-power, entirely from storage batteries, but I presume that the General Purposes Committee, in giving the contract to the Hammond Company for their system of direct running, were actuated solely by an apparent economy, sacrificing the most important element of thorough efficiency. In so important a public building as the Mansion House, the first consideration should be to obtain a light that can be depended upon for not going out just when most needed, and an artistic arrangement of the lamps is also very essential. When the Mansion House was first lighted it was with wretched arc lamps, in the style of a railway station or iron foundry, and the present display is far from suitable to the civic palace."

Digitized by Google

THE ELECTRIC LIGHTING ACT.—The Board of Trade have just presented to Parliament a report on the subject of the applications made to them under the provisions of the Electric Lighting Act of 1882, during the past year, and their proceedings thereon. From it we learn that only one application for a Provisional Order was received up to the 21st of December last; and this was from the Chelsea Electricity Company (Limited), who asked for power to light a portion of the parish of Chelsea. The report states that this order has not been proceeded with. Since the date of the last report, the Board have revoked the whole of the Provisional Orders (fifty-five in number) granted to companies in the session of 1883, with the exception of the Birmingham order, the provisions of the orders as to the appropriation and deposit of capital not having in any case been complied with. With regard to the orders granted in the session of 1884, the Board have received applications for their approval of an extension of the time within which the deposit of capital should be made in respect of the Fulham District Electric Lighting Order, 1884, granted to the West Middlesex Electric Lighting Company; and of the St. James, St. Martin, and St. George, Hanover-square (West London) Electric Lighting Order, 1884, granted to the West London Electric Lighting Company. In each of these cases the Board (after consulting the local authorities) approved of an extension of the time until July 3, 1885. In the case of the first-mentioned order, an application for approval of a further extension of time has been received, and is now under consideration. Since their last report the Board have received applications for two licenses; and they are now under consideration. One was made by a local authority (the Dalton-in-Furness Local Board), and the other by Mr. J. E. Veale, of St. Austell.

ELECTRIC LIGHTING OF PUBLIC BUILDINGS.—The Exeter Town Council are erecting a new lunatic asylum, under the supervision of Mr. Wilkinson, architect, of that city, and for a considerable time the question of the lighting of the buildings has been under consideration. Some months ago the Council declared in favour of the adoption of the electric light, and at their last meeting, held a fortnight ago, this decision was reaffirmed. Several tenders to install the electric light have been sent in, and the architect has presented a report on the tenders, based on the calculation that a light of 8,000 candle-power would be sufficient. The tenders received from companies not using storage batteries were as follow:—J. D. Andrews and Co., Glasgow, capital to be sunk £2,490, total annual cost £768; F. Geere Howard, London, capital £3,210, annual cost £347. 16s.; Walker and Olliver, Cardiff, capital £2,310, annual cost £722. 4s.; Simplex Company, Manchester, capital £3,086, annual cost £467. Companies using storage batteries:—Anglo-American Brush Company, capital £2,410, annual cost £541. 4s.; the Consolidated Electric Company, capital £1,735, annual cost £339. 17s.; Gulcher Company, capital £2,960, annual cost £578. 4s.; Woodhouse and Rawson, capital £2,426, annual cost £527. The latter tender was for 6,000 candle-power. It will be observed that the estimate and absolute annual tender for maintenance of the Consolidated Electric Company is the lowest. This company proposed to do the greatest amount of work with a large storage battery, which it is claimed would give a more even-current and steadier light than if the electromotive force was supplied direct from the dynamos. A week or two ago a deputation, consisting of several members of the committee having charge of the asylum arrangements, went to London to inspect the various installations there. They gave details at the last council meeting of inspections they had made of the electric lighting at First Avenue Hotel, Holborn, the Criterion Theatre, Gatti's Restaurant, the offices and factory of the Consolidated Electric Company, Cow Cross-street, E.C., the premises of Spink and Son, Gracechurch-street, the Inventions Exhibition, the Bank of England, the offices of the Peninsular and Oriental Steamship Company, Messrs. Swan and Edison's works, Holborn Viaduct, Messrs. Andrew and Co., High Holborn, the Holborn Restaurant, the Savoy Theatre, the Law Courts, the Stock Exchange, the Crystal Palace, and other places, and the committee considered "the electric light, from a proper installation, is brilliant, reliable, perfectly safe, and under complete control." At the next meeting of the council the committee will recommend one of the tenders above mentioned for acceptance.

SUGAR REFINING BY ELECTRICITY.—In reply to many of our readers who are anxious for further information upon this subject we publish the following statement, which has been forwarded to us by Mr. J. U. Robertson, 5, Baltic-buildings, Redcross-street, Liverpool, on behalf of the Electric Sugar Refining Company, of New York. This gentleman says:—"Cable advices to myself and others in Liverpool have just been received from several gentlemen who were present at the demonstration of this company's process of refining sugar, which was given on the 15th inst., in New York, on a scale much larger than has heretofore been attempted. The result was most satisfactory, for in the short space of seven hours some 40 barrels of refined sugar were produced from a common grade or ordinary West Indian refining sugar, without making any syrup or soft sugars, the whole product being the highest grade of refined sugars, the analysis of which exceeds 99·50 per cent. cane sugar. The conditions upon which this demonstration was to be given (as per my letter advices received previously) were to be as follows:—(1) Five to six tons raw sugar were to be refined at one time; the same to be carefully weighed and analysed; the analysis to be by Professor Chandler, of Columbia College, New York, who is a well-known public analyst. (2) The premises in which the machine stood to be thoroughly examined by the gentlemen present, to see that no sugar was there except the raw which had been brought to be refined. Every precaution to be taken to see that no communication from without was possible. (3) This done, they should certify the same in writing, and then the work of refining would commence and continue, they being in and around the premises during the time occupied. (4) The inventor undertakes, as a condition of the demonstration, to return them refined sugar of such sizes as they may designate before the demonstration, and to give them in weight of refined sugar within one per cent of the weight of the entire saccharine matter in the raw sugar, including glucose or invert, as shown per the analysis of Prof. Chandler, and he also undertakes that the said refined sugar will analyse not less than 99·50 per cent. cane sugar. (5) These things being performed, the demonstration was to be considered conclusive and satisfactory in every particular. The reason for giving this demonstration, which is one of many, is to secure from the sale of shares the balance of the capital required to complete the machinery and put it into operation, and I am advised that sufficient have been contracted for, pending this demonstration, to furnish that, including a small number of shares which have been placed in my hands for that purpose. I am also advised that the machinery to refine 500 tons of sugar per day of twenty-four hours is far advanced in its construction, and will now be pushed forward to completion. Mr. Robertson adds that he will be happy to supplement this information if desired, and also to show samples of the sugar produced by the company's process.

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(Continued from page 25.)

The starting point for determining the number of lines created by a certain exciting power, P, is Ampère's theory of electro-magnetic action, according to which a closed plane circuit traversed by a current is equivalent to a magnet, the axis of which is at right angles to the plane of the current, and the magnetic moment of which is numerically equal to the product of current into area enclosed by the conductor. The moment of a magnet is the product of strength of pole and length. If we assume the magnet to be a very short cylinder, having for base the contour of the current, it becomes a magnetic shell, and we can also say that the magnetic action of a closed current is equal to that of a magnetic shell of the same contour. It is not necessary that the shell be in a plane; it may form part of a curved surface, but its contour must coincide with the current. It is also not required that its two end faces be parallel, though this is the simplest case applicable to straight bar magnets; but it is necessary that the density of magnetic matter distributed over the end faces should in every point be inversely proportional to the distance between the end faces at that point. A magnetic shell may therefore be wedge shaped, and by assuming a number of such shells put together we can obtain a curved magnet. If the shells are all magnetised the same way—that is to say, if the contiguous end faces of neighbouring shells contain equal amounts of magnetic matter of opposite sign—they will all neutralise one another, and the magnetism on the free end faces of the first and last shell only remains.

Imagine we have n such shells put together so as to form a horse-shoe magnet, with parallel pole faces a distance d apart. The number n can be chosen without any other limitation but this, that it shall be sufficiently large to make the thickness of each shell very small. We can therefore choose n to be equal to the number of turns of wire wound on our horse-shoe magnet, and if C be the current in this wire (given in absolute measure, viz., amperes $\times 10^{-1}$) the magnetic moment of each shell will be C S, where S is the area enclosed by the current. We have hitherto tacitly assumed that all the shells are equal in outline and thickness, or in other words that the cross section of our horse-shoe magnet is the same in all places. This is not necessarily the case; if the cross section of the magnet varies gradually, the density, σ, of magnetic matter spread over each face of a shell will also vary gradually, so that the total amount of magnetic matter σ S remains constant and the magnetism of contiguous shells will still be eliminated, leaving only the first and last face covered with magnetic matter. But if the cross-section should vary in an abrupt manner, which would be the case if the magnet were composed of straight slabs put together at right angles with projecting corners, this continuity would of course be interrupted and a certain amount of free magnetism would be noticeable at the corners and at other intermediate points. We might express this by saying that whilst in the perfect magnet the lines of force leave and enter the system of shells only at the end faces, in the imperfect magnet a certain number of lines pass out or in at intermediate points. It need hardly be pointed out that a perfect magnet, such as we have described, is only a mathematical conception and connot be found in nature. To make it possible it would be necessary that the iron offer absolutely no resistance to the lines of force, and that it have no saturation point—in other words, that there should be no limit to the number of lines which one square inch of iron can accommodate. But although no such magnet is possible, it is convenient to regard it as an ideal standard of perfection with which the magnets practically possible might be compared.

The total magnetic moment of the n shells is evidently n C S, and this by the definition above given must be equal to the product of strength of poles by their distance. In the case under consideration the poles are not two mathematical points, but two surfaces charged with free magnetic matter to the total amount $\pm \sigma$ S. For the sake of simplicity we assume the surface density of distribution to be constant, and the two surfaces to be parallel to each other, and separated by an air space, d (Fig. 16.) The magnetic moment is therefore σ S $d = n$ C S.

To find the intensity of field within the air space we must first determine the total number of lines passing across, and then divide that number by S. We have defined unit field that where there is one line of force to every square centimetre (*see* p. 512, Vol. XIV). If we have a free magnet pole equal to unity it will be urged along in the direction of the lines in a unit field with the force of one dyne. Now assume we have a fixed unit pole, and we describe around it as centre a sphere with a

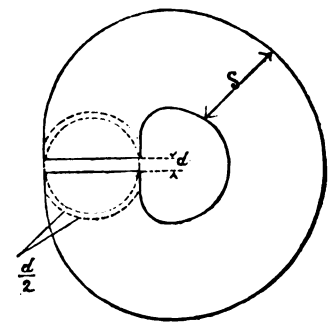

Fig. 16.

radius of one centimetre; then, if we bring another unit pole of opposite sign on to the surface of this sphere, it will be attracted towards the centre with the force of one dyne. We may shift the position of the second pole on the surface without doing any work and without increasing or decreasing the attraction. In this respect the case is similar to that of a unit pole moved in a plane which is at right angles to the lines of a uniform field. If the force which tends to lift the unit pole out of this plane is one dyne, we express the strength of the field by saying that to every square centimetre of surface there is one line of force. Similarly there must be one line of force to every square centimetre of surface on the sphere described around our fixed unit pole, and since the surface of a sphere of radius 1 is 4π, we find that the total number of lines radiating from a unit pole is 4π. If the amount of free magnetism at the pole instead of being unity were σ S, the total number of lines would evidently be

$$Z = 4\pi\sigma S.$$

In this equation σ S can be replaced by its value resulting from the former equation, and we find

$$Z = 4\pi \frac{n C S}{d}.$$

The density of lines per square centimetre, or the intensity of field, is the ratio between Z and S.

$$I = \frac{4\pi n C}{d}.$$

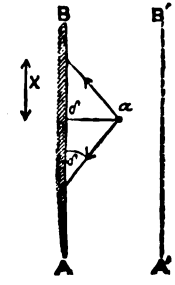

Fig. 17.

An objection might be raised regarding the validity of this formula on the ground that $4\pi\sigma$ S is the total number of lines radiating from a point in which σ S units of magnetic matter are concentrated, whereas in our case this quantity is spread over the surface S; and what holds good for a point need not

Digitized by Google

necessarily hold good for a surface. A somewhat more rigorous proof is therefore desirable. Let in Fig. 17 a be a unit pole, placed at a distance δ from the polar face A B, over which magnetic matter is supposed to be equally distributed with a surface density σ. An elementary ring $2\pi x\,dx$ attracts the pole in the direction of the arrows with a force $\frac{2\pi x dx.\sigma}{\delta^2+x^2}$, this force being distributed over a cone which intersects the plane A B at the angle α. The vertical resultant of the attraction is therefore $2\pi\sigma\sin\alpha\,\frac{x\,dx}{\delta^2+x^2}$.

Substituting for x $\delta\,\frac{\cos\alpha}{\sin\alpha}$ and for dx $\delta\,\frac{d\alpha}{\sin^2\alpha}$ we obtain the vertical attraction due to the elementary ring

$$2\pi\sigma\cos\alpha\,d\alpha.$$

This integrated over the limits $1\ \alpha=0$ and $\alpha=\frac{\pi}{2}$ gives the total attractive force due to the surface A B . . . $2\pi\sigma$.

In fixing $\alpha=0$ as one of the limits of the integral, we make the assumption that δ is very small in comparison with the extent of the polar surface. If another such surface were placed opposite the first, as indicated by the dotted line A′ B′, so that the point a lies between the two poles, and if A′ B′ were charged with an equal amount of magnetic matter of opposite sign to that distributed over A B, it would repel the unit pole with a force $2\pi\sigma$, which, added to the force of attraction, gives

$$4\pi\sigma$$

as the total force with which a unit pole would be urged across the air space. There must therefore be $4\pi\sigma$ lines of force to every square centimetre of the field. If the distance d between the two poles is very small, this is approximately the density of lines over the whole surface, and we find the total number of lines between the poles $Z=4\sigma\pi S$, the same expression as that found above.

If, instead of having only one air space d, we had two, each $\frac{d}{2}$ centimetres wide, nothing would require to be altered in our formulæ. Referring again to Fig. 16, imagine the polar faces to be cylindrical cavities as indicated by dotted lines and a cylindrical armature to be placed between, having a clearance of $\frac{d}{2}$, the intensity of the field will be

$$I=\frac{4\pi nC}{2\,\frac{d}{2}},$$

or, if we write $\delta=\frac{d}{2}$ for the air space and P for ampere turns of exciting power we have

$$I=\frac{4\pi P\,10^{-1}}{2\delta}.$$

This is the average intensity of field taken along the neutral diameter of the armature, not around its circumference. As a matter of fact, the first and last face of our system of magnetic shells are no longer parallel planes, but cylindrical surfaces. It has, however, been pointed out in the beginning of this article that it is only the contour of the shell and not the nature of its end face which need be considered, and hence our formulæ are equally applicable to the case of shells with cylindrical faces. Let b and d be the length and diameter of armature in an ideal dynamo with perfect field magnets, then the total number of lines of force passing across the armature would evidently be $I\,b\,d=Z$.

$$Z=\frac{4\pi P\,10^{-1}}{2\delta}.\,b\,d,$$

which might also be written in the form

$$Z=\frac{4\pi P\,10^{-1}}{\left(\frac{2\delta}{b\,d}\right)}$$

If we consider the fraction $\frac{2\delta}{b\,d}$ to represent a resistance, we have here Ohm's law translated into the magnetic circuit. According to this we have the following relation for a perfect electro magnet. *The total number of lines in a magnetic circuit is proportional to the ratio of exciting power and magnetic resistance.* In reality our magnets are not perfect, and hence the law is only approximately true; but for practical purposes the approximation is sufficiently near to enable us to use the above equation with some modifications for the designing of dynamos. If we have to do with a perfect magnet $\frac{2\delta}{b\,d}$ is the only resistance in the circuit. It is of the character, length divided by area, the same as the electical resistance of a conductor.

Since the field magnets and the armature offer also a certain resistance to the lines of force, we have to take it into account as well as the resistance of the air space. The equation for the number of lines crossing the armature must therefore be modified to

$$Z=\frac{P}{R_F+R_A+R\alpha},$$

where R_F represents magnetic resistance of field magnets.
R_A „ „ „ „ „ armature
$R\alpha$ „ „ „ „ „ air space

P being, as before, the exciting power in ampere turns. Suitable coefficients must here be introduced in the expressions for the three resistances to obtain the number of lines in such a measure that the product $Z\,N\,t\,n$ gives the electromotive force in the armature in volts.

(To be continued.)

BRAUER'S DYNAMO-METRIC BRAKE.*

BY H. WALTHER-MEUNIER.

Two striking charisteristics distinguish this brake, the invention of Mr. Brauer, from others of the same class. Firstly, it does not require when in action that its frictional surfaces should be constantly wetted; with ordinary wooden brakes this is absolutely necessary. Secondly, once the clutching action is established the brake regulates itself automatically, and further, there is not required, as with the ordinary brake, a long and cumbersome lever. An analogous arrangement to that of Mr. Brauer has been suggested by Mr. Kratz in his essay upon the dynamometric brake.† In the Brauer apparatus, instead of wooden jaws hugging the rims of the pulley, an iron band is used for flat-rim pulleys, and wire-ropes for grooved pulleys. The apparatus is composed of the following assemblage of parts:—

1st. The iron band or wire rope. 2nd. The clutch producing arrangement and the regulation of the tension of the clutch-producing bands or ropes.

The clutch or pressure of the bands or ropes upon the surface of the rim of the pulleys produces a friction corresponding to the effective work of the motor. The moment of this friction multiplied by 2π gives the work produced per revolution. To calculate this it only needs to determine an equal moment given by the additional charge or weight p, augmented by the weight of the regulating organs, the two weights affixed to the axis of the pulley, and p the moment required to maintain the system in equilibrium. The iron band applied to an ordinary flat-rim pulley is provided with four double guides k (Fig. 1), to retain the band in position, which is fixed up from the underside by means of a stirrup bolt and link and a safety cord l^1 l^2, in such a way as to allow the band to have a play of 100 milimetres. These safety measures can be modified according to local circumstances, and when the under part of the pulley or drum is inaccessible.

The clutching or frictional parts are actuated in the following manner:—The wire band is attached at its two ends in one instance to the point of the application of resistance a, and

Digitized by Google

in the other to the point of rotation b by a lever $a\ b\ c$. The point c of this lever is attached at d by means of a winding tackle $e\ e_2$, and a spring f, to the upper end of the wire band. The cord of the winding tackle after leaving e is passed round the friction-roller g. The operator by slightly pulling the cord will be able to produce the tightening or clutching action in such a way that the weight p is lifted up and equilibrium established. In order that this condition may not be influenced by the tension of the part of the cord from e_2 to g, it is only necessary to fix the friction-roller in such a way as to be in line with the axis of the pulley or drum. The moment of this tension will then be *nil*. The friction-roller is not absolutely indispensable, but its application permits the operator to control and watch the action of the dynamometric brake at some distance from it. The automatic regulation is effected, according to the variations of the friction, by the combined action of the coil-spring f and the cord h. It will be seen that if, owing to the band producing excessive friction, the weight p is lifted above its mean position, the cord h will be stretched, augmenting the tension, and consequently elongating the coil-spring f. The result is a diminution of the clutching action of the band, and the weight p will be lowered. The weight l, which replaces the necessity of attaching the cord h to the floor-boards, should be sufficiently heavy to equal the strain liable to be brought upon the cord h. The lifting tackle should always be suspended in such a way as to reduce the traction upon the cord h to a minimum, and so that the influence of this factor upon the condition of equilibrium in general need not be taken into consideration.

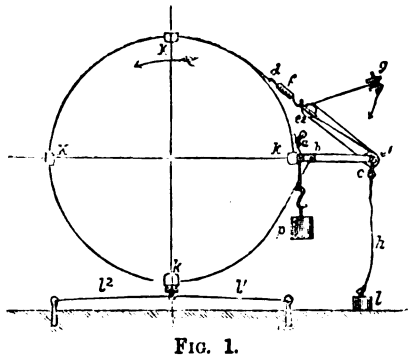

Fig. 1.

The effective work performed can be ascertained by the following formulas :—

$$T = \frac{(P+p)\,L\,\pi}{716{\cdot}2} \text{ horse-power (French).}$$

In which T = the effective work in horse-power;
P = the load-weight in kilos.;
p = the weight in kilos. of the regulating organs suspended to the point of attachment P;
L = the distance from the centre of the pulley to the point of attachment of the weight in metres;
π = the number of revolutions per minute.

Lubrication is effected by means of oil lubricators placed at the position marked a (Fig. 1). It is useless to try to cool the frictional surfaces by the use of water. If the pulley-rim presents to the surrounding air a surface equal to 10 square decimetres per horse-power, then the rim may be allowed to attain a temperature of as much as 100° Centigrade (212° Fahrenheit) without inconvenience. These conditions are generally realised by the flat rim or band pulleys, and by grooved pulleys, in each groove of which there is provided a wire rope of from 7 to 8 millimetres in diameter. For brakes of small dimensions the tackle arrangement can be advantageously replaced by means of a tightening screw. In the case of a vertical shaft the weight may be attached to a bent lever, or to a chain passing over a friction-roller. The use of the tackling arrangement is only very rarely required, seeing that the condition of equilibrium is maintained with great uniformity. Care must, however, be taken to attach the cord very firmly so that in case of need the tightening or clutching action can be instantly diminished or increased.

The following is a description of the dynamometric brake employed by Mr. Walther-Meunier to test the Brauer principle :—The application was made to a four-grooved pulley 2·15 metres (7ft.) in diameter, measured from the base of the grooves. The intention of the application was to measure the effective work performed by a 25 horse-power engine. The under portion of the pulley for a quarter of the π ran in a cemented race; it was therefore necessary to have recourse to a precautionary measure different from those already described. Figs. 2 to 8 show the arrangement devised by Mr. Brauer especially for this purpose. Each of the grooves was provided with a wire rope, A A, in two portions, one passing over the pulley, the other under. One of the ends of the upper portion was attached to the skate B (Fig. 3),

Fig. 2.

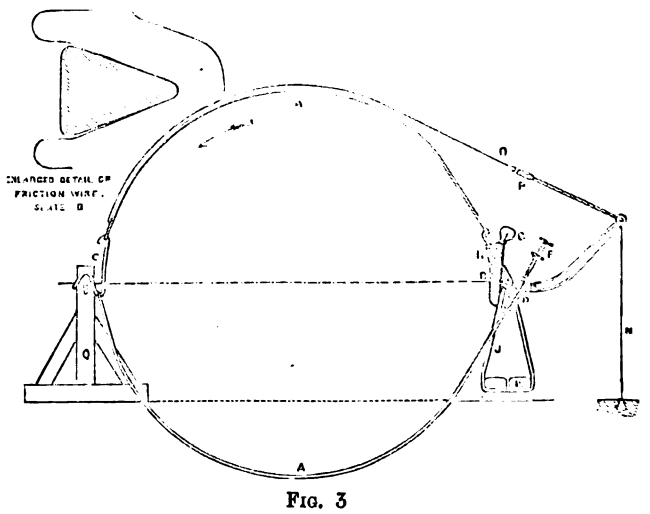

Fig. 3

a sketch of which, and enlarged, is shown (Fig. 2). The other end is attached to the double hook C (Fig. 3). The under wire rope is twisted round the hook C, and is attached at its other extremity to the rim of a stirrup D (Figs. 3 and 7), furnished with a boss, E, through which there works a tightening screw, F, provided with an actuating handle or wheel. The iron skate B (Fig. 3) is perforated obliquely to receive the lubricating medium from a needle lubricator, G. One end of the bent bar H is firmly let into the skate B; the apex of this bent bar H is twisted so as to carry the suspension bar I, firmly held in position by two nuts at its two ends.

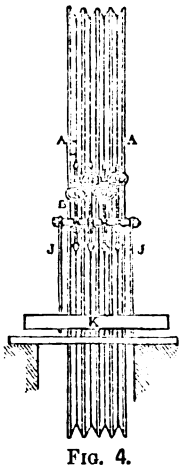

Fig. 4.

This suspension bar carries the stirrups J (Fig. 8), upon which rest the plates K for receiving the weights. The suspension bar also carries the bent lever L. This lever is provided with a bolt, M, upon which the pressure of the tightening screw F (Fig. 3) is exerted. The other end of the bent lever L is attached by a wire cord, N, to the floor, and also to the regulating apparatus, by means of a thin steel band, O, attached to the hook C, which through the coil-spring P is in direct communication with L. The complete arrangement of the brake is composed of four systems, similar to that already described, one for each groove of the pulley.

The brake being in perfect equilibrium, the centre of the highest end of the lever L was about 1 metre (3ft. 3in.) above

Digitized by Google

the ground, and the cords N were arranged so as to be neither too slack nor too tight, but all about the same tension. In order to indicate the perfection of equilibrium, Mr. Brauer alternately relaxes and extends these cords. In this way the slightest variable resistances impossible of avoidance are compensated for in a sufficient manner. In the event of the breakage of one of the parts, the hook C is caught on the cross-piece of the framework support Q. The coil-springs P, owing to their attachment to the long bar of the lever L are never subjected to a greater strain than 10 kilograms (22lb.). In order to put the brake in action the suspension-bar should be placed exactly at the height of the centre of the axis of the pulley, and in the instance of the application above described the centre of the eye of the highest end of the lever L is about one metre above the ground. The cords N

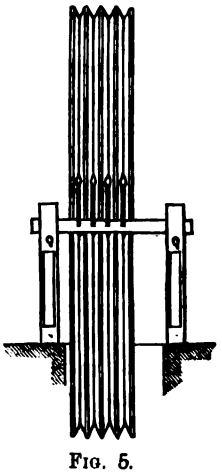

Fig. 5.

and the highest screw-attachments P should then be fixed. Before applying the brake it should be ascertained whether the pulley turns in the direction shown by the arrow (Fig. 3) without dragging the brake. The lubricators should now be examined, and a little oil should be poured into the grooves of the pulley. After weights are placed on the weight-suspender the tightening screw should be very gently turned until it lifts the weights from the platform, and leaves them in gentle oscillation near the condition of equilibrium. If the tightening screw is applied too violently, the cords will be extended without lifting the weight.

The following is a summary of the observations made by Mr. Burghardt, who has carefully tested Brauer's dynamometric brakes. Needle lubricators do not sufficiently lubricate the apparatus ; tallow is preferable as the lubricating medium. The brake worked well during the time the temperature of the pulley rim did not exceed 35° to 40° centigrade, and even up to 80° centigrade the action was still satisfactory, but the

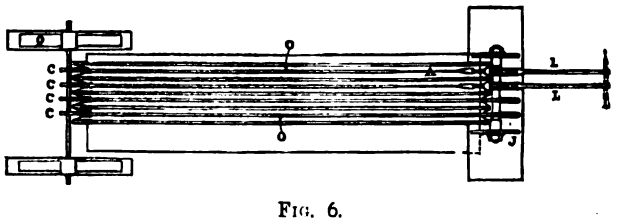

Fig. 6.

lubricating medium became too fluid, and was thrown off the grooves by the centrifugal force due to the speed of the pulley. The Brauer brake worked well for two hours with a load corresponding to 25 horse-power :—

1. The necessity of continually cooling the pulley rim by subjecting it to a stream of water, which is a great drawback to the use of ordinary brakes, is in the Brauer brake avoided.

2. The brake is not so cumbersome, and can be applied to motors *in situ* and in confined spaces.

3. The oscillations are very limited, and consequently the observations are more exact than with the ordinary brake, and the diagrams obtained by the indicator are clean and clear, and easy to calculate.

On the other hand, the Brauer brake is relatively rather more costly than those of the ordinary class, and it requires in its application a little more care than those of the ordinary and unscientific class. The excellence of the Brauer brake is such that Messrs. Walther-Meunier and Burghardt decided to utilise it in their investigations of the following important questions :—1st. Whether it is advisable to work a steam engine with or without condensation. 2nd. Whether it is advisable to work with low pressure and low expansion, or with high pressure and high expansion. 3rd. What is the variation of the effective work under different loads.

The motor used in order to investigate these questions was on the Collman system, having four distributing valves, two for inlets and two for exhaust, the former having variable expansion gear. The engine was also provided with a condenser. The mechanical parts of the engine were perfectly

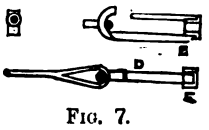

Fig. 7.

balanced. The engine had a piston stroke of 600 millimetres (about 24 inches.) Its piston was 301 millimetres (12 inches) in diameter. The engine was worked at 70 revolutions per minute. The net weight of the brake was established as suggested by Mr. Brauer, neglecting the weight of the iron bands or wire ropes, coiled springs, &c. The following details enter into this account :—

Distance from the centre of the pulley axis to the point of attachment of the weights	1·185	metre.
Weight of the four cast iron skates ...	31·50	kilos.
„ „ lubricators.....	0·90	„
„ load carriers or suspenders	10·20	„
„ attachment levers	39·25	„
Total	81·85	„ (180lbs.)
Deduct the weight of the four safety hooks	6·50	„
Net weight of the brake =	75·35	„ (166lbs.)

Corresponding at 70 revolutions to the work, equivalent to 8·727 horse-power, or

$$T = \frac{1}{716{\cdot}2} \times 75{\cdot}35 \times 70 \times 1{\cdot}185 = 8{\cdot}727 \text{ h.p.}$$

The number of revolutions per minute was registered by a counter connected to the main shaft. Twenty diagrams were taken at each end of the cylinder, all those indicating any irregularity in the working of the brakes being eliminated.

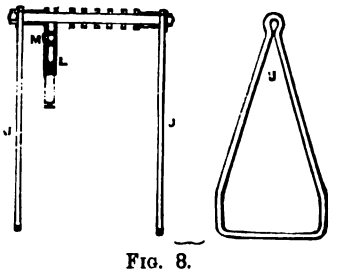

Fig. 8.

The following is a summary of the conclusions arrived at by Messrs. Walther-Meunier and Burghardt :—1st. It is desirable to work a steam engine with a load proportionate to its dimensions. 2nd. It is desirable to employ condensation where local circumstances will permit, even for engines of comparatively small dimensions, on the condition that the condenser and its actuating mechanism are carefully and intelligently proportioned. 3rd. It is desirable, even with single-cylinder engines, to work with the highest pressure. 4th. It is highly desirable that every possible precaution should be taken to ensure a perfect and continuous lubrication of the frictional parts of all steam-engines without exception. The serious study of lubricating methods and lubricants deserves the attention of all steam-users.

THE POSTMASTER-GENERAL'S REPORT.

The Report of the Postmaster-General for the year ended 31st March, 1885, is, as usual, both satisfactory and interesting so far as the Post Office is concerned; but in respect to the Telegraph branch of the public service there is little that is gratifying and still less encouraging to be found in the Report. Such, at least, is the view one may naturally take of it at this present juncture. Mr. Shaw-Lefevre says "the telegraph business of the country shows but little development;" and in proof of it he cites the fact that there has been only an increase of 435,000 messages during the past year. Under a tariff reduced by fully one half there will doubtless be a huge "development" in the sense of an increased number of messages; but probably also a not less marked development on the wrong side of the revenue account. The steadily diminishing increase of telegrams which has taken place during the past five years is attributed to "stagnation of trade, the competition of the telephones, and the rapidity of the letter post." As there are no signs of improvement to the telegraph's advantage in these respects the time is not happily chosen for an experiment which will add immensely to the capital account whilst greatly lessening the ability to pay interest upon it.

The ruling powers have convinced themselves, however, that an augmented increase in the number of telegrams is not only desirable of itself, but that anything short of it "cannot be regarded as satisfactory." We ourselves should be rather disposed to say that the annual increase had reached its maximum, and that no considerable development in that direction can or ought to be expected. The Telegraphs have now been worked by the State for fourteen years. During the first three or four years the annual increase was at the rate of two to three million messages; but since then, except in the year 1880-81—a year of exceptional prosperity—the increase has been steadily falling. And this is not to be wondered at. No business can hope to go on for ever increasing at the same rate; if it keeps pace with the progress and population of the country this is as much as we have any right to expect. That there has been an enormous development in the telegraph business under Post Office administration is unquestionable. Commencing with a total of barely ten million messages in 1870-71 it had doubled that number in five years, and trebled it in the year 1880-81. From that year the increase has slackened, as was to be expected, and proceeds now at something like half a million a year, the total number of messages for the past twelve months being 33,278,459. Notwithstanding a very considerable addition to the number of telegraph offices open, and to the increased facilities afforded to the public for the transmission of their messages the increase of traffic is diminishing; and we can only infer from all this that the telegraph business of the country has reached its normal limit or thereabouts, and that nothing but an artificial stimulus will provoke any material enlargement.

Whether the stimulus of a sixpenny rate will add to the financial prosperity of the service is a very doubtful matter indeed. The late Postmaster-General points out, and indeed almost makes it a matter of complaint, that the revenue has not contributed anything for two years past to the interest on the capital invested. This, however, is accounted for by the outlay in anticipation of the increase of traffic under the reduced tariff, the expenditure last year alone exceeding the revenue by about £36,000. But in a few years' time this expenditure must have been required to meet the ordinary increase of business under the existing tariff; and we cannot agree with many writers on this subject who allege that all this money will be wasted should the sixpenny telegram scheme fall through. What is really to be apprehended is that sixpenny telegrams will contribute less to the payment of interest on capital than shilling telegrams do at present. It is gratifying, however, to notice a confirmation of our oft-repeated opinions in the action of the new Postmaster-General. Three words for sixpence with free addresses may be thought by some people preferable to twelve words addresses included. We have no objection to offer if the public are anxious to take their ha'porth of beer out of a quart pot in the fashion suggested by Lord John Manners; but we regard it as a full and unqualified confession that the free addresses are a financial mistake, and that in some way or other they must be either abolished or paid for in a disguised form.

As to the effect on the Telegraph revenue of the development of private Telephone business, we can hardly doubt it; yet it is remarkable that the figures do not betray this influence in the locality where we should expect to find it. Local London telegrams appear to increase in the same ratio as provincial telegrams, and we cannot perceive any marked falling off in the former during

Digitized by Google

the past three years, when metropolitan telephony has been so greatly extended. But accepting the Postmaster-General's opinion on this point, it is plain that the Department does not reap any large compensation for its losses on account of the rival Telephone Companies. The total royalties paid by them amounted to only £19,370 last year—a sum which at once disposes of the outcry against the extortion of the Post Office, and of the excuse on this account put forward by the companies to justify their high charges. Neither have they much cause for complaint on the score of Post Office competition. Twenty-seven Telephone Exchanges in various country towns, with a total list of 1,141 subscribers, represent the amount of departmental activity in this direction, and the total receipts do not much exceed the trifling royalty on their business contributed by private companies. "The full effect of the Telephonic competition," says the late Postmaster-General, "remains to be seen, but I cannot doubt that the Telegraph Revenue has been and will be adversely affected." If this be so it is a matter for regret that we find no indication of a policy designed to check the adverse effects of that competition. Sooner or later this will have to be done; and it is perfectly evident that reducing the rates for ordinary telegrams will not do it.

We are glad to notice that attention has been drawn in this Report to the advantage the nation derives from its connection with the Telegraphs in the help it affords to military expeditions which are now of almost periodical occurrence. On several former occasions the employment of Royal Engineers in the Postal Telegraph Service has enabled the military authorities to despatch a body of trained and experienced soldiers to the seat of war who otherwise would have been hard to find and far less efficient. No fewer than six officers, and one hundred and six men have been so detached for active service in Egypt and Bechuanaland within the past year. To this number must be added about thirty of the Reserve Telegraphists belonging to the permanent staff of the Post Office, most if not all of whom are still performing arduous and honourable service for their country either in Upper Egypt or at Suakim.

CORRESPONDENCE.

SIXPENNY TELEGRAMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If you would allow me to somewhat disagree with your expressions on sixpenny telegrams, I should like to state that I entirely fail to see any difficulty in harmonising Mr. Lefevre's and Lord John Manners' schemes relating to this matter. The plan of tariff that seems to me a very fair and business-like compromise I will shortly detail. Let the sixpenny telegram consist of a message of six words, the address of recipient, and three words to indicate the sender, being free; and let additions made to the sender's address and the message be charged at the rate of two words for a penny. The advantages would be these: a shilling telegram would contain almost as much as one now sent at a similar charge; the address of recipient and the message would not often exceed Mr. Lefevre's maximum number of words; the difficulty of shortening necessarily intricate addresses would be avoided; the Bill's passing would be assured, and a boon conferred on the whole of the country. This tariff, too, would be as remunerative as Mr. Lefevre's, while six words for sixpence and a penny charge for every additional two would give a definite meaning to a sixpenny telegram. Of course, a message of six words is short, but it was to facilitate the sending of such a message that the Bill was originally introduced.—Yours, &c.,

CECIL J. BLACKER.

LOCALISING A PARTIAL EARTH FAULT IN A CABLE WHEN A RETURN WIRE IS NOT OBTAINABLE.

TO THE EDITOR OF THE ELECTRICIAN.

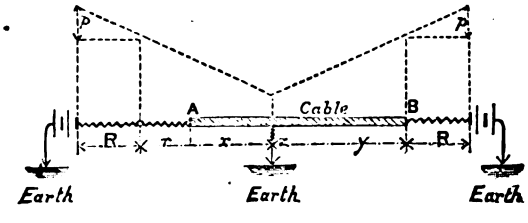
SIR: I have read with great interest and pleasure Messrs. Anderson and Kennelly's modification of Blavier's well-known test in your issue of 17th July.

Every electrician who has had to localise variable and high resistance faults in a single cable (where no loop or return wire was available) must have felt how inapplicable Blavier's method was, more especially if the fault was near his end of the line.

"Fall of potential" tests no doubt yield excellent results when carefully applied; but the necessary apparatus and skill are not always at hand. I believe, therefore, that Messrs. Anderson and Kennelly's test will be often preferred, and they certainly deserve thanks from all whose duty it is to localise faults in submarine cables, by having not only devised the test, but in having so fully and clearly demonstrated its limits of sensitiveness.

It has occurred to me that instead of applying the "fall of potential" test at one end of a cable at one time only, it might be found practicable in certain cases to apply the test simultaneously from each end in the following manner:—

Join up batteries of *precisely* the same E.M.F. with *equal* resistances R and R in circuit with the cable A B. Introduce a resistance, r, at the end A nearest the fault, until the difference of potential p and p obtained between the ends of the resistances R and R becomes precisely the same, taking care to



eliminate or allow for any natural cable current by balancing the same with a compensating battery placed between R and r or R and the B end of cable, as the case may require.

Then the distance from A to the partial earth fault at z will be $x = \frac{l-r}{2}$ ohms, where $l = n + y$ ohms the total copper resistance of the cable.—Yours, &c., ANDREW JAMIESON.

College of Science and Arts, Glasgow, July 18, 1855.

INVENTIONS EXHIBITION GRIEVANCES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read the letter from Mr. Henry F. Joel in your paper, I am extremely glad to see that someone has taken the matter up, as I certainly consider that there is room for very considerable improvement. My own experience is this. It is now nearly three months since the Exhibition was opened, and still some portions of the Eastern Arcade are very badly lighted. The authorities have now made three attempts at the lighting. Firstly they had oil lamps, secondly arc lamps which they moved since, and now they have some crystal lamps, and even yet these are not permanently lighted. Now that the Exhibition has been opened half its term it is almost time something was done.

I also think that the pass business is a very great inconvenience and troubles a great many.—Yours, &c.,

July 22nd, 1885. AN EXHIBITOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the letter of your correspondent, H. B. Joel, in last week's issue, the difficulty about personal tickets being used by others than their rightful possessor would be met by their being pasted on the back of a *carte de visite*, as was done at the Paris Exhibition of 1878, the Brussels Exhibition of 1880, and is the rule at the present Antwerp Exhibition.—Yours, &c., J. W. P.

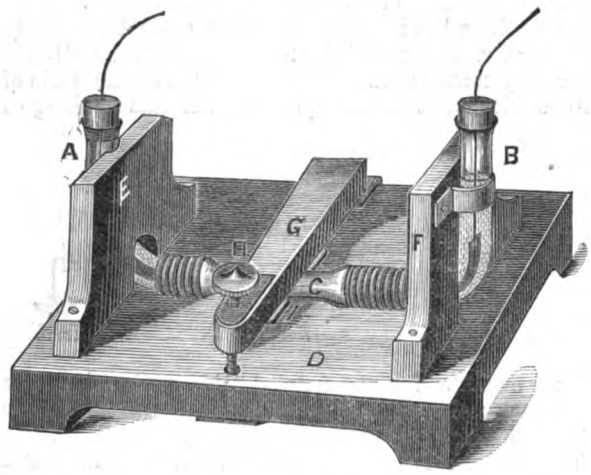
A SIMPLE FORM OF VOLTAIC-REGULATOR*.

BY DR. G. GORE, F.R.S.

Having used the following apparatus with satisfactory results in a very large number of experiments, in which comparatively feeble voltaic currents varying from about one-fiftieth to one-thousandth of an ampere were employed, I beg leave to describe it.

The construction and action of the instrument are indicated by the annexed sketch, but in order to adapt the apparatus to currents of the range of strength mentioned below, it is desirable to state the dimensions of some of its parts. A B are two glass tubes, about 2·0 cm. diameter, and 10·0 cm. high, bent at right angles. Their upper ends are about 20 cm., and their lower ones 8·0 cm. apart; and the latter are united by a vulcanised india-rubber tube of their own diameter. The tubes are nearly filled with a three-fourths saturated solution of non-acidified cupric sulphate, in which are wholly immersed two electrodes of sheet copper, 8·0 cm. long and 1·5 cm. wide, the lower ends of which project some distance within the india-rubber tube. The tubes are supported by the base-board D and the two wooden uprights, E F. By means of the



wooden lever G, which is about 2·5 cm. wide, and has a hinge at one end and a thumb-screw, H, at the other, the middle part of the vulcanised tube, resting upon a small block of wood, I, may be very gradually and strongly compressed.

With tubes and electrodes of the dimensions given, any strength of current, ranging from ·0001 to ·05 ampere, may pass without interference of polarisation; and, with a steady lever, a screw of slow motion, and the india-rubber tube slightly stretched, the current can easily be regulated to a 1-100,000th of an ampere.

ON THE "GROUPING SYSTEM" FOR THE DISTRIBUTION OF ELECTRICITY.†

BY W. H. SNELL, A.S.T.E. AND E.

The method of distributing electricity at approximately uniform potential, which has been termed the "Grouping System," may be briefly described as follows:—

The whole area to be supplied is divided into districts, in each of which there should be an approximately equal consumption of electric energy. The mains supplying these districts are connected with one another in series—that is to say, the negative main of the first district is joined to the positive of the second, and so on. Within the limits of each district the distribution is effected by means of a parallel system of branch mains, either double or multiple. In order that the current from the dynamo may *without waste* be equalised throughout the system (notwithstanding the continuous variation in the demand) a "compensating room" is established in each district. The compensation is effected by means of secondary batteries which are connected in parallel with the lamps, and are to be capable of maintaining the required difference of potential and of supplying the requisite number of ampere-hours of current *per diem*.

The advantages of such a system may be summarised as follows:—

(1.) Economy of metal in the mains.
(2.) De-centralisation of engine station.
(3.) Comparative immunity from breakdown.
(4.) Increased life of lamps.
(5.) Probable economy of working expenses.

Most of these points are too obvious to need any explanation. With regard to the second, it will be clear that the engines may equally well be placed in any one of the districts. The last claim refers mainly to the fact that the machines may cease running at night, the current being still available from the batteries; but there will of course be something to set upon the other side of the account for maintenance of the cells.

Before we proceed to discuss the conditions of working there are two or three points which it may be as well to note in this place. It is obviously desirable that while the machines are running the work should as far as possible be performed by them, rather than by the cells. It will be shown hereafter that by a proper adjustment of the E.M.F. of the dynamos the total work of the cells may be permanently maintained at (or very nearly at) its minimum *possible* rate under any given distribution of lamps. It is not essential that a compensating room should be placed in any particular part of its district. It is, however, desirable that it should be at, or near to one end rather in the centre — *which* end is indifferent, except in certain special cases. By placing the rooms at the junctions of the districts we may have two sets of batteries in each, and thus only half as many rooms will be required. On the other hand, by placing the cells in the centre of a district the "economical length" of the district is doubled. Again, in any one or more districts we may place more than one set of cells, and join them up in series, in order that we may make use of the "multiple main system" within the limits of these districts. This plan is principally of service where the number of lamps which have to be fed from branches is large compared with the number which can be supplied directly from the main. It is of course understood that branches may be taken off from any part of the main (no matter where the battery is placed), so that as far as the dynamo is concerned the distribution is *from a line of constant potential*, instead of being from a point, as in other systems. It will thus be apparent that the system is very flexible, and it is probable that it can readily be adapted to any conditions likely to occur in practice.

The following are some of the questions that will have to be considered before the system can be practically applied:—

(1.) To determine into how many districts the area to be supplied should be divided.

(2.) To adjust the "economical length" of the system with its measured length under the given conditions.

(3.) To determine what (if any) adjustment should be made in the E.M.F. of the machine so as to maintain the work of the batteries at a minimum.

(4.) To provide for a proper control of the charge and discharge of the batteries from the engine station.

(5.) To arrange for a continuous supply of current. The difficulty here is to keep the potential in the mains at its proper value during the time that the cells are being charged.

No doubt there are other problems which will present themselves for examination, but in the meantime we will deal with those here enumerated *seriatim*.

We have, then, first to determine into how many districts the area to be supplied shall be divided. For this purpose, we may make use of the equation

$$E_x = N E_y + C R, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where N is the number of districts, E_y is the maximum E.M.F.

---

* Read before the Birmingham Philosophical Society, June 11, 1885.

† This method was first described in a patent obtained by Rear-Admiral Arthur in May, 1882. In the year 1884 Mr. Preece (without being aware of the existence of such patent) employed accumulators in this way in his experiments on street lighting at Wimbledon. This, I believe, is the first and only instance in which the method has been put into practice.

Digitized by Google

of each battery *during charge*, C is the maximum charging current, and R is the (estimated) resistance of the external circuit of the dynamo during charging. E_x is therefore the maximum E M.F. which will be required at the terminals of the dynamo. But this E.M.F. must not be permitted to exceed the limit of safety and of economical insulation. *Then we may make N as large as possible consistent with these conditions.* It will, however, be better to take N somewhat below its highest permissible value, because we can then undertake to charge any cells belonging to private consumers, besides allowing for future extension. In reckoning the value of N in equation (1) it is to be noted that any district served by n mains will for this purpose count as $(n-1)$ districts, inasmuch as the fall of potential is, in such a case, equivalent to that in $(n-1)$ districts supplied by *two* mains only.

Having thus determined the number of districts, the next point is to compare the "*economical length*" of the system with its actual linear measurement taken along the course of the main from the + to the − terminal of the dynamo. Let the actual length of the system when so measured be called L. Let λ be the economical limit for the distance between any battery and the farthest lamp in its district; and let L_1 be the economical length of the whole system. Then we must arrange so that L_1 shall not be less than L. But for L_1 we have

$$L_1 = N \lambda \alpha \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where (assuming for the present that multiple mains are not employed) the factor α depends upon the position of the compensators in their several districts. If every compensator is situated at one end (either + or − end) of its district, then α is obviously equal to unity. But if the batteries are placed each in the centres of their districts, α will become equal to 2, which is its maximum value under the given condition. When the cells are all in some (the same) intermediate position α obtains a proportionate intermediate value. When, in the more usual case, the relative position of the cells differs from district to district, we must put

$$\alpha = \frac{\alpha_1 + \alpha_2 + \ . \ . \ . \ \alpha_N}{N} \quad . \quad . \quad . \quad . \quad (3)$$

But when multiple mains are introduced the values of α_1, α_2, &c., will depend upon the number and also upon the relative size of the intermediate mains. I have dealt with this point at length in a paper which appeared in *The Electrician* (Vol. XIV., p. 412). The values of α_1 α_2 . . . found as before must be multiplied by the value of expression (5) (of that paper). Within the limits of practice this multiplier will lie between (about) 1·6 to (about) 2·6. It will be observed that in (2) N represents the actual number of districts, and not the number reckoned as in (1).

We have next to find the economical length of each district; this we have already called λ. Let the resistance of a part of the main of length λ be put equal to r_2, then the value of r_2 must be such that when the dynamo is not at work the difference of potential at the terminals of a lamp at distance λ from the battery (along the main) shall not be less than the required percentage of the maximum potential which is permitted.

Let this percentage be expressed by the fraction q.
" E_2 be the E.M.F. of the battery during discharge.
" ρ " " resistance of the battery.
" l " " " of one lamp.
" μ " " maximum number of lamps which in practice one battery will be required to supply for any length of time.

Then we must have the following relation

$$q E_2 \frac{1}{\frac{l}{\mu} + \rho} = E_2 \frac{1}{2r_2 + \frac{l}{\mu} + \rho} \quad . \quad . \quad . \quad . \quad (4)$$

But also let M be the total number of lamps in the system, and put

$$\mu = \frac{p M}{N},$$

where p is some fraction for which we can readily estimate a value. And ρ will be some known function of the number of amperes which the battery can deliver, and can therefore be expressed as a function of μ.

Let us put $$\rho = \frac{s}{\mu} = \frac{s N}{p M}.$$

Making these substitutions in (4), and transposing, we shall get

$$r_2 = \frac{N (l+s) (1-q)}{2 M q p} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

It appears, however, that s will always be negligible in this position.

Next let r_3 be the *economical resistance per unit length of the main* under the given conditions. If this unit length be written λ_1, we shall have for the value of λ

$$\lambda = \lambda_1 \frac{r_2}{r_3} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The value of r_3 will be determined from calculations of "the mean annual thermal current." * Now, if C_θ be the mean value of this thermal current per district, we may conveniently put Sir W. Thomson's "equation of economy" into the form

$$W = C_\theta \sqrt{b \rho_1} \quad . \quad . \quad . \quad . \quad . \quad (7)$$

where W is the weight of the conductor in pounds per unit of length, ρ_1 is the resistance of a conductor of unit length weighing one pound, and b is a term depending only upon the financial data.† Now, if for W we put $\frac{k}{r_3}$, k being a known constant, we shall obtain from (7)

$$r_3 = \frac{k}{C_\theta} \sqrt{\frac{1}{b \rho_1}} \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Now, in (6) substitute this value of r_3, and also substitute for r_2 from (5); we then get for λ

$$\lambda = N \lambda_1 C_\theta \left\{ \frac{(l+s)(1-q)}{M q p k} \right\} \sqrt{b \rho_1} \quad . \quad . \quad (9)$$

All the terms in this expression are known with more or less accuracy. Finally, substituting this value of λ in (2), we obtain L_1, the economical length of the system. It should be observed that, although the above expression for λ contains the term N in the numerator, yet inasmuch as C_θ will vary almost exactly inversely with N, the value of λ is really very nearly independent of N.

Now if L (the total economical length) is less than L_1 (the real or required length), we may either attempt in some way to increase the value of expression (9), or we may make some alteration which will increase the value of α in (2), or else we must consent to depart from the economic value of r_3 in (8). Or, finally, we may possibly find it desirable to increase the number of districts.

Consider next what should be the E.M.F. at the terminals of the dynamo in order that the total work done in or by the batteries may be maintained at a minimum value, while the dynamo is running. We also require an expression for the current through the lamps, let E_1 be the required difference of potential at the terminals of the machine. And suppose, in the first instance, that we have the same number of lamps alight in every district, and let this number be n. Under these circumstances it is clear that E_1 should have such a value that no current shall flow through the batteries either in the positive or the negative direction. And we shall show that this condition is fulfilled when we maintain the value

$$E_1 = N E_2 \left(\frac{l + n r_2 \alpha}{l + n r_2} \right) \quad . \quad . \quad . \quad . \quad (10)$$

Now, in this expression if α be unity (a value which we have already seen it never much exceeds) then the term within the brackets is also equal to unity, and we have simply

$$E_1 = N E_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

But this last expression does not contain n, therefore in this

* For an explanation of this term, and the method of calculating it, see a paper read before the Society of Telegraph-Engineers and Electricians, June 11th, 1885, "On the Calculation of Mains for the Distribution of Electricity."

† This is taken from the paper already alluded to.

Digitized by Google

case the current through the cells will still be zero whenever the number of lamps alight is the same in each district, whatever that number may be.

But again, whatever may be the value of α (within the known limits), inasmuch as r_2 is very small indeed compared with l, it will be seen that the expression for E_1 in (10) varies very little with different values of n, so that in any case we make E_1 constant at a point determined by selecting a mean value of n. But further, it will readily be seen that although in practice this condition (that the number of lamps in use is equally distributed) is not actually attained, yet the same value of E_1 must maintain the work of the batteries (positive or negative) at a minimum, whatever may be the actual distribution at any given time. When the distribution is not equable, then the work being done in or by the cells is least in those districts where the value of n is nearest to its mean value throughout the system at that particular moment. It does not seem possible to obtain any perfectly general solution of the distribution of work, but special cases may often be treated by the aid of the equations we are about to develop.

We have now to show how equation (10) has been determined. It is well known that in any network of conductors containing various sources of E.M.F., if there is any branch in which the current is zero that branch may be removed, together with whatever source of E.M.F. it may contain, without causing any alteration in the distribution of current in the remaining branches. If, therefore, we establish the condition of an equal distribution of lamps and such a value of E_1 as will make the currents through the batteries equal to zero, we may then select one district and find expressions for the current in the lamps and cells in this district under the assumption that throughout the remainder of the system the batteries have been disconnected, and these expressions will hold good for this district when the connections are re-established.

We may therefore reduce the system *pro tem* to the case indicated in Fig. 1. The lettering is taken to represent the resistances of the different parts of the circuit.

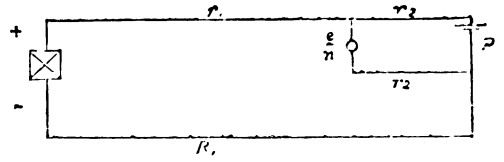


FIG. 1.

We will now put

$$r_1 + R_1 = r' \; ; \quad \rho + r_2 = r'' \; ; \quad \frac{l}{n} + r_2 = r \quad . \quad . \quad (12)$$

And if R be put for the total resistance of the mains from the + to the − terminal of the dynamo, we may write for r'

$$r' = (N-1)\frac{l}{n} + (R - r_2) \quad . \quad . \quad . \quad . \quad (13)$$

But it is clear that R stands in the same relation to r_2 as L_1 stands to λ; that is,

$$R = N r_2 \alpha \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Making this substitution in (13), we have finally

$$r' = (N-1)\frac{l}{n} + r_2 (N\alpha - 1) \quad . \quad . \quad . \quad (15)$$

Next, let c_1' be the current in r' due to the dynamo, and let c_1'' be the current in r'' due to the battery.

These currents are in opposite directions, so that if c_1 be the resultant current in r'

$$c_1 = c_1' - c_1'' \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

Again, let c_2' be the current in r'' due to the dynamo, and let c_2'' be the current in r'' due to the battery.

These currents are also in opposite directions, so that if c_2 be the resultant current in r''

$$c_2 = c_2'' - c_2' \quad . \quad . \quad . \quad . \quad . \quad . \quad (17)$$

Finally, let c be the current in r then having regard to the sign of c_2, we shall have

$$c = c_1 + c_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

We proceed to express these currents in terms of E.M.F. and resistance. For the sake of brevity we will put

$$A = (r\,r' + r\,r'' + r'\,r'').$$

Then we shall obtain

$$c_1' = \frac{E_1 (r' + r'')}{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

$$c_1'' = \frac{E_2\, r}{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (20)$$

$$\therefore \; c_1 = \frac{E_1 (r + r'') - E_2\, r}{A} \quad . \quad . \quad . \quad . \quad . \quad (21)$$

$$c_2' = \frac{E_1\, r}{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (22)$$

$$c_2'' = \frac{E_2 (r + r')}{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (23)$$

$$\therefore \; c_2 = \frac{E_2 (r + r') - E_1\, r}{A} \quad . \quad . \quad . \quad . \quad (24)$$

and

$$c = \frac{E_1\, r'' + E_2\, r'}{A} \quad . \quad . \quad . \quad . \quad . \quad . \quad (25)$$

Now when c_2, the current in the battery, is equal to zero, we have from (24)

$$E_2 (r + r') - E_1\, r = 0 \quad . \quad . \quad . \quad . \quad (26)$$

Substituting for r' and r from (15) and (12), and transposing, we obtain for E_1, the value already quoted in (10),

$$E_1 = N E_2 \left(\frac{l + n r_2 \alpha}{l + n r_2} \right) \quad . \quad . \quad . \quad . \quad (10)$$

This expression has been discussed already.

Next, let c_0 be the current per lamp when n lamps are burning, so that $c_0 = \frac{c}{n}$.

Then, if for the time we regard r' and r'' as fixed resistances, by substituting in (25) we shall get

$$c_0 = \frac{E_1\, r'' + E_2\, r'}{(l + n r_2)(r' + r'') + n\, r'\, r''} \quad . \quad . \quad . \quad (27)$$

Now r'', and therefore also r_2, is always a very small quantity, therefore looking at (15) we see that r' varies very nearly inversely with n, so that n really vanishes from the last term of this denominator. And further, as l is extremely large compared with r_2, n is of very little importance in the first term. So that we may conclude that the current per lamp is sufficiently independent of the number of lamps alight in its own district, and it may be shown (although, perhaps, it will follow *à fortiori*) that it is also practically independent of the number of lamps in any or all of the remaining districts.

It is, however, more important to note the relative effect upon c_0 of any variation of E_1 or of E_2. If in (27) we substitute for r' and r'' from (15) and (11), we shall obtain

$$c_0 = \frac{n E_1 (\rho + r_2) + E_2 \{ l (N-1) + n r_2 (N\alpha - 1) \}}{n A} \quad . \quad (28)$$

from which we see that any small change in E_1 has an extremely small effect upon the current in the lamps, compared with that which would follow a similar change in E_2. It may be worth while to put down the complete expression for A; this may be written, with very close approximation,

$$A = \frac{1}{n^2} (l + 2 n r_2) \{ l (N-1) + N n (n r_2 + \rho) \} \quad . \quad (29)$$

Now, suppose that E_1 is maintained at the value $N E_2$, and let us also suppose that in one district the number of lamps burning changes from n to n_1, and let n_1 be greater than n. If we now take c_0 to indicate the *normal* current per lamp, the current traversing the whole number of lamps in this district may be considered to have increased by the quantity

$$(n_1 - n)\, c_0,$$

and the greater portion of this additional current will be supplied by the battery, as we shall presently show. But that some part of the extra current must come from the dynamo

Digitized by Google

is obvious, because the change has caused a decrease in the resistance of the dynamo circuit. And this additional dynamo current will traverse the cells in the remaining (N – 1) districts in the negative direction, that is as a *charging* current.

Now change n to n_1 in a second district. There is now a somewhat smaller positive current delivered by *two* batteries, and an increased negative current in the (N – 2) batteries. And if n is charged to n_1 in the remaining districts successively, the negative current increases continually while traversing a decreasing number of batteries, and the positive current decreases continually while traversing an increasing number of batteries; so that when in all districts n has become n_1 the negative current has been eliminated, and the positive current is reduced to zero, and the batteries are again idle.

Following out this reasoning, we may conclude that when n varies indefinitely throughout the system the current in the batteries, whether + or –, will always be least in those districts where the number of lamps burning approximates most nearly to the average number alight per district, at the given time, whatever that average number may be.

From this we may also deduce as a corollary that the total work done in or by the batteries under any given distribution of lamps is least when E_1 has such a value as would make the battery currents zero if the lamps in use were equally distributed. But as we cannot write any general expression for r' it does not seem that any more formal proof can be given.

The following proposition is also, perhaps, worth recording. Let the number of lamps burning in (N – 1) districts be not very different from an average number, say n. In the remaining district let the number be n_1. Then the *extra* current will be equal to

$$\pm (n-1)\, c_0,$$

and this current will be divided between the battery and the dynamos in the (approximate) ratio

$$l(n-1) \;:\; \mathrm{N}\, n\, (2\, r_2 + \rho).$$

From this it will be seen how very slight is the effect of a disturbance in one district upon the current, either in the lamps or the batteries of any other.

(To be continued.)

PECULIAR CLASS of CHEMICO-ELECTRIC CURRENTS.*

BY DR. G. GORE, F.R.S.

In an ordinary voltaic cell chemical corrosion of one of the metals is an essential condition of production of current. In the present experiments I have endeavoured to obtain electric currents by means of chemical change in electrolytes without such corrosion, and without applying different temperatures to the two plates.

The plan adopted has been to obtain the current by means of a chemical alteration in the liquid alone:—To select a very easily decomposable electrolyte, or one in a state of unstable chemical equilibrium, either at or near the temperature at which it spontaneously changes, immerse in it two different metals, neither of which is corroded by the liquid, but which, in consequence of their static electric polarity produced by contact would be differently related to the chemical change, and thus determine the direction of the current produced by it; and, after immersing the metals, raise the temperature of them and of the liquid equally.

The mode of procedure was to immerse a pair of plates, one being of gold and the other of platinum, in the liquid; connect them with a galvanometer, note the amount of steady deflection at atmospheric temperature, and then gradually raise the temperature of the mass of liquid, until the chemical change occurred; and in cases where the liquid returned to its original chemical state on cooling, allow it then to gradually cool, and note the direction and amount of the deflection. The galvanometer employed was an astatic and differential one, the two coils of which, each having a resistance of 50 ohms, being connected as a single undivided circuit.

The liquids tried were:—1, peroxide of hydrogen, ten volumes, containing much chloride; 2, a rather strong solution of potassic chromate, acidified with sulphuric acid; 3, the same mixture, with some spirit of wine added to it; 4, a weak solution of permanganate of potassium; 5, the same, with some sulphuric acid added to it; 6, a weak solution of potassic iodide, mixed with dilute sulphuric acid; 7, the same, mixed with nitric acid; 8, a mixture of strong nitric acid and three times its bulk of water; 9, a mixture of wet, freshly precipitated green cupric hydrate, and solution of potassic sulphate containing free potassic hydrate; 10, a solution of chloride of cobalt containing some hydrochloric acid; 11, a solution of subchloride of copper in hydrochloric acid.

Experiment 1.—Hydric peroxide. Platinum was positive and gold negative at 50° F., deflection 1·0°; at 100° F. 5·0°; at 160° F. 8°, and at 200° F. 14°. By cooling to 110° F. the deflection was 0; and at 100° F. gold was positive 1·0°.

Experiment 2.—Potassic chromate acidified with sulphuric acid. Platinum positive at 58° F. 2·0°; at 140° and 180° F. 6·0°. It is probable that the increase of current in this case was due to decrease of resistance by rise of temperature.

Experiment 3.—The same solution, with alcohol added to it. Platinum positive at 58° F. 1·0°; at 90° F. 7·0°; at 120° F. 8·0°; at 160° F. 9·0°. The liquid was decomposing quickly at about 120° F.

Experiment 4.—Permanganate of potassium solution. Gold positive at 50° F. 1·0°; at 100° F. 3·0°; at 140° F. 0°; at 180° F. platinum positive 5·0°; and at 200° F. gold positive 2·0°.

Experiment 5.—The same solution, with sulphuric acid added. At 52° F., gold positive 2·0°; at 80° F. 4·0°; at 90° F. 0°; at 95° F. platinum positive 2·0°; at 150° F. 25·0°; and at 210° F., deflection 60° degrees. A thin film of manganic oxide formed on each metal.

Experiment 6.—Potassic iodide, mixed with dilute sulphuric acid. At 58° F., gold positive, and gradually and increasingly so up to 180° F., at which temperature the deflection was 70°. Gas appeared on both metals.

Experiment 7.—Potassic iodide, mixed with dilute nitric acid. At 58° F. gold positive 8·0°; at 90° F. 30·0°; at 110° F. 40·0°; at 125° F. 50·0°; and at 180° F. 60·0°. The liquid in this and the last experiment commenced to become brown at about 120° F.

Experiment 8.—Mixture of nitric acid and water. At 55° F. gold positive 5·0°; at 100° F. 40·0°; at 180° F. 35·0°; and at 200° F. 10·0°. On boiling the liquid, the current suddenly increased and became irregular.

Experiment 9.—The mixture of cupric hydrate with solution of potassic sulphate and hydrate. At 62° F. gold positive 2·0°; at 66° F. platinum positive 1·0°; at 80° F. gold positive 5·0°; and at 160° F. 4·5°. The hydrated oxide of copper began to decompose at about 160° F.

Experiment 10.—Solution of chloride of cobalt and hydrochloric acid. No current was produced by heating.

Experiment 11.—In an additional and somewhat different experiment, suggested to me by Professor G. G. Stokes, a bent glass tube, U shaped, was filled with a nearly saturated solution of subchloride of copper in partly diluted hydrochloric acid. Two perfectly similar electrodes, cut from contiguous parts of the same sheet of pure copper, were connected with the galvanometer, then suspended in the liquid of the two limbs, and one of the limbs gradually heated by means of a surrounding water bath to about 210° F. The heated piece became gradually and increasingly positive to the cold one, and acquired a coating of minute crystals of metallic copper. The heating occupied about five minutes; but by continuing it ten minutes longer, the current gradually and largely decreased.

Extensive investigation would be necessary in order to ascertain to what causes the currents produced in these cases are due.

GLAESENER SECONDARY BATTERY.

All inventors—or rather devisers—of electrical accumulators or secondary batteries endeavour to obtain a maximum of surface with a minimum of weight in their electrodes. MM. Glaesener Freres, of Châtillon, near Arlon, in the Belgian province of Luxemburg, seek to attain this desideratum by rolling continuous bands or tapes of lead, having minute projections on both surfaces, so that, when wound spirally into a disc, they permit of the liquid passing freely between them. They assert that their accumulator is the lightest for a given duty of any hitherto brought out on the Continent. This battery has lately been brought into notice through its application to the lighting by Swan lamps of the Luxemburg Prison, which will be referred to below.

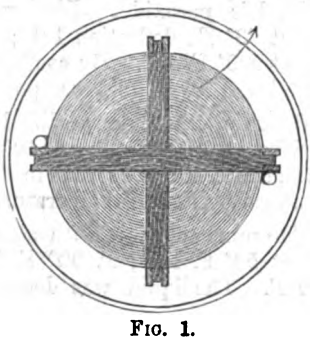

FIG. 1.

The lead tapes forming the electrodes are:—1 centimetre or 0·4in. wide, and about 0·4 of a millimetre thick, having on both sides small hemispherical projections, varying from 0·1 to 0·5 of a millimetre in diameter. Each tape 30 metres, or nearly 100ft. long, is wound spirally, so as to form a disc of 5in. diameter, weighing 1,200 grammes, or 2lb. 10oz., and presenting an effective surface of, on an average, rather over 62 square decimetres or six square feet, 100 square inches. Although these electrodes are used without any coating, they lend themselves admirably to receiving a coat of red lead, which is held between the folds of the spiral. Besides, as soon as the accumulator begins to act the red lead is held more closely, on account of the expansion of the electrode and the consequent tightening of the spirals.

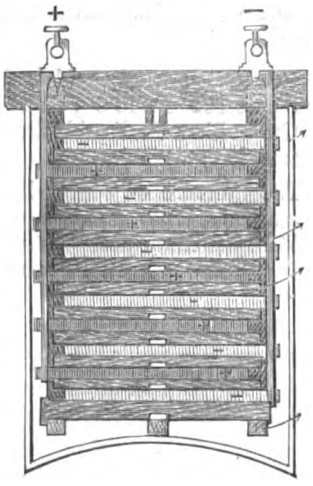

FIG. 2.

The discs are arranged, as shown in the accompanying vertical and horizontal sections, in a pile of 11, with wooden crosses between, coated with a highly insulating varnish. To the bottom cross, which is stronger than the rest, are pinned four wooden uprights, which are attached to the cover, provided with a handle, so that the whole may be inserted and withdrawn from the glass jar, containing dilute sulphuric acid. The outer ends of the electrodes, arranged alternately positive and negative, as shown in the section, are wrapped round vertical lead rods, put in connection with the binding screws. An electrode has been sent to us which has been in use six hours a day for more than a year, and the lead of which, though brittle, is not eaten through.

MM. Glaesener Freres lighted their own works at Châtillon about two years ago with twenty 10-candle Swan lamps, maintained by 25 accumulators, the lead of each of which weighs 6 kilogrammes, or 13lb. They are charged, from four to six hours a day, with a current of 55 amperes at 15 volts; and there has been no hitch hitherto. The next installation was at the Saint-Leger Roller Flour Mill, which is driven by water, so that no additional expense was incurred for the power absorbed. A small Gramme dynamo charges forty accumulators, the lead of each of which weighs 18 kilogrammes, or about 40lb.; and these maintain 16 Swan lamps. The installation cost, in round numbers, 1,500fr. = £60; so that, putting 10 per cent. for interest and depreciation, and 50fr. = £2 for maintenance and renewals, the expense of a year's lighting, for an average of 10 hours a night, is 200fr. = £8, or 6 centimes (about a halfpenny) an hour. This is just the same price that was before paid for paraffin; but the lighting is now 50 per cent. better, without counting the diminished risk from fire.

The prison at Luxemburg is lighted by twenty five 10-candle Swan lamps, distributed among the workshops, passages, and guard house, and maintained by 30 accumulators, the lead of each of which weighs 12 kilogrammes, or 26lb. They are charged by a Gramme shunt dynamo, of the workshop type, giving out 70 to 80 volts at 21 amperes when making 1,500 revolutions a minute. A charge of 70 to 80 ampere-hours is found sufficient for the lighting required, viz., a few hours every night, one lamp, however, being maintained all through the night. On one occasion, by way of trial, the accumulators, charged for an hour, by a current of 70 volts at 14 or 15 amperes, maintained a Swan lamp of 50 volts at 0·65 ampere for about 20 hours. The dynamo is driven by a broken-down old portable engine, the speed of which is so far from being constant that it certainly would not do for electric lighting, but for the accumulators acting as a regulator, and so maintaining a steady light.

THE BAZIN ROTATIVE BATTERY.

M. Hospitalier, in *L'Electricien*, gives the results of his experiments with the Bazin rotative battery as follows:—

Duration of discharge	4h. 30m.
Quantity	198,000 coulombs 55 ampere-hours
Total work disposable	1,218,900 joules 122,000 kilogrammetres 0·45 horse-hour (French)
Consumption of zinc (not including motor)	112·6 grammes
Mean consumption per cell	160·9 „
Effective consumption per ampere-hour	2·93 „
Theoretic consumption ditto	1·213 „
Mean force of battery during discharge	75 watts
Mean force of one cell	10·74 „
Maximum ditto	15 „
Initial E.M.F. (7 cells in series)	13·1 volts
Final E.M.F.	11·9 volts.

The battery thus experimented with consisted of eight cells, one of which served to rotate the zincs, &c., at a rate of about one revolution per minute whilst the other seven were coupled in series in the outer circuit. The results obtained are not very brilliant, but M. Bazin promises to furnish a more perfect form of his battery for future experiment, asserting that the one to which we have alluded was in an elementary form only.

THE ELECTRIC LIGHT AND VEGETATION. — Professor Holdefleiss has noticed that beet seed sown in soil which was exposed to the electric light germinated two days earlier than similar seed without the action of the electric light. Another interesting observation is that of Herr Scholler, who has noticed an exceptional luxuriance of beets in a small plot which had been struck by lightning.

CONVERSAZIONE AT THE TECHNICAL COLLEGE, FINSBURY.

On Thursday, the 16th inst., a students' *conversazione* was held at the City and Guilds of London Technical College, Finsbury, about 600 members being present. There were several exhibitions of various subjects, and the whole of the arrangements, under the management of Mr. A. Newman Lawrence, were carried out in a satisfactory manner. Amongst those present as representing the council of the institute were Messrs. R. P. Barrow, Joseph Beek, Rokeby Price, J. Travers Smith, Robins, Jennings, Sawyer, and Mr. Phillip Magnus, the director and secretary of the institute. During the first hour, *i.e.*, from 7 until 8 p.m., the exhibits were graphically explained to the visitors, and the mode of working in many cases freely illustrated by experiment. In the basement there were exhibitions of mechanical apparatus and machinery; woodwork, lathes in motion; metal work, lathes and other machinery in motion; and steam engines (which supplied power for all the machinery and the electric light, there being no gas in the establishment). There were also dynamos at work lighting the building, and other stationary machinery. On the ground floor were to be seen students' drawings, heat apparatus, and some electrical apparatus, such as is used by the advanced students of the college; and a telpherage model at work. These of course attracted considerable attention, but not so much as the articles shown on the first floor. Those consisted of photographs, and various scientific instruments, microscopes, electrical apparatus, and a phonograph. On the second floor was a chemical laboratory, microscopes, respectropes, and polariscopes. These exhibits were open all the evening. In room No. 21, on the first floor of the college, a lantern exhibition was given. Prof. Silvanus P. Thompson, with his usual kindliness, conducted a series of optical and polariscopic experiments, and Mr. John Castell-Evans was equally deserving of thanks for his clear and lucid exposition of the mysteries of spectrum analysis and crystallization. A variety of lighter fare had also been provided. A concert, given by the Technical College choir and others, attracted a large audience, and a comedy drama, entitled "Alone," performed in the large hall by Messrs. F. Rawson, S. Williamson, Baker, Sulman, and the Misses Del'Orme with great effect, followed closely upon its heels. After an interval, dancing commenced in the large hall, and was maintained with great spirit until a late hour.

The arrangements were very ably carried out by the secretaries of the various departments. These were: Mr. F. Lewis and Mr. Southern (Exhibition Committee), Mr. S. Williamson (Dramatic Committee), Mr. F. M. Smith (Concert Committee), Mr. H. Codd (Decorating Committee), Mr. H. F. Marks (Dance and Refreshment Committee), Mr. Cockburn (fountain), and Mr. H. A. Lawrence (organising secretary).

LEGAL.

United Telephone Company (Limited) v. Bassano and another.

In the High Court of Justice (Chancery Division), before Mr. Justice North, this case was continued.

Professor Forbes was examined on behalf of the defendants. He said that at the date of Edison's patent the only meaning of "diaphragm" known was that which separates one part of a structure from another. His reading of Edison's specification was that it was essential to the invention that the diaphragm should be between the resonant chamber and the tension-regulator. He found nothing in defendants' instrument which corresponded to Edison's diaphragm. He had performed various experiments with defendants' apparatus, using first the whole, then the speaking trumpet and base detached from the wooden back board; then with the speaking trumpet and base detached, but with the pencils and blocks forming the tension-regulator composed of different materials; then with a speaking trumpet made of lead, then with a speaking trumpet made of soft putty and laid on a mass of straw, and so on, the results shown being that the desired telephonic effects were obtainable by means far removed from those designated by Edison in describing his invention of the diaphragm. The witness then went through Edison's specification, and discussed the various kinds of tension regulators there described. He stated that in all of them it was essential that they should be semi-conductive and compressible, as well as resilient. The defendants' instrument acted as a microphone. It consisted of pieces of carbon loosely attached to each other, and Hughes, who was the inventor of the microphone, always used them with a sounding-board. So used the microphone reproduced even the sound of a fly crawling on the board. Hard carbon was not a semi-conductor, but a good conductor of electricity for telephonic purposes; it was not a good conductor for telegraphic purposes, being, in fact, the worst of all the good conductors in common use.

In cross-examination the witness said: The state of knowledge as to telephonic engineering had vastly improved since the date of Edison's patent. The function of taking up the sound waves was not the sole function of the diaphragm shown in Edison's specification. There was also the compressing of the tension-regulator, which, however, was the result of taking up the sound waves, and no other function was described. Being asked as to the action of the annular base of speaking tube itself on the sound waves, he said it did not act in the same way as Edison's diaphragm, but only faintly and indirectly. That base would, however, if used without the speaking tube, act better with it. The shape of the piece of wood in the transmitting part of any telephone only signified in respect of degree. The back board in defendants' apparatus would perform the function of interfering with the sound waves and probably add to the vibrations of the rest of the instrument, and so act on the tension regulator. He did not suggest that, having regard to the functions to be performed, it made any difference whether the diaphragm was in front, behind, or at the side of the tension regulator, nor that the shape was material. According to his (Professor Forbes's) understanding of Edison's specification, his instrument would not act without a diaphragm or tympan as described by him.

Mr. Conrad Cook, consulting engineer, was then called. He described certain experiments from which he ascertained that the microphonic results could be obtained without the assistance of any resonating contrivance. His reading of Edison's specification was that the diaphragm should be of a non-resonant character, that it should be of a tympanic shape, and not be susceptible to moisture or atmospheric conditions. The wooden part of defendants' transmitter would answer those requisites very indifferently, and in his opinion the defendants' invention in that respect was not covered by Edison. Then his tension-regulators as described were such as would in all instances be sensibly compressible, and varying their electrical resistance under variations of compression. Hard carbon as used by the defendants would not possess those characteristics. In witness's opinion Edison's tension-regulators would not act without the diaphragm.

The witness was cross-examined at considerable length upon Edison's specification, and the report of a lecture on the telephone delivered by himself in 1879 before the Society of Arts. He agreed with Professor Forbes that, having regard to the descriptions of the telephones described by the various inventors, the shape of the wooden portion was merely a question of degree in each case. In his opinion Edison's tension-regulator would not be commercially useful unless used with the diaphragm described by him.

After the re-examination of Mr. Cook, certain experiments were carried out by the defendants, his lordship first making the statement that he did not regard the experiments as evidence, but merely as explaining and illustrating the descriptions given in the witness box. The putty transmitter supported on a heap of straw, the lead transmitter, and the solid block of wood were used in turn.

Mr. Shoolbred, telegraphic engineer, was then called, but was not cross-examined.

Mr. F. T. Hollins, a co-patentee with the defendants of the instrument alleged to be an infringement, was next examined.

Mr. G. H. Bassano, an electrical instrument maker, and one of the defendants, then gave his evidence. He found in Edison's transmitter a diaphragm consisting of a disc made of mica. There was in the invention of himself and his co-patentees no diaphragm as described by Edison. The function of the conical mouthpiece was to concentrate the air waves upon the tension-regulator. The function of the annular base was to hold the carbon blocks which support the carbon pencils. The function of the wooden back board was to support the whole instrument. Edison only recommended one material for the diaphragm—namely, mica—as being of a non-resonant character, that being essential because a resonant material would tend to resound only to its own pitch, and so interfere with distinct articulation. Edison further considered that the influence of moisture must be avoided, and he did not mention wood as suitable for a diaphragm. The characteristic feature of Edison's tension-regulator was that it should be of a semi-conductive material; hard carbon was not a semi-conductor but a good conductor. Hard carbon was elastic and therefore compressible to some extent, but not in the sense Edison intended. In defendants' tension regulator hard carbon was used, working by a microphonic action, however that operated, which was as yet a mystery.

In cross-examination, Mr. Bassano said that the conical mouthpiece in defendants' transmitter would take up the sound waves to some extent, and so with the base and the back board. The vibration given to those parts would certainly be imparted to the carbon blocks and the pencils. The result would be change of position in the carbon surfaces in contact, for there would be some pressure. The surface contact would vary to the extent of the compressibility of the carbon, and the resistance to the electric current would be varied synchronously with the variations in the sound waves. Defendants' transmitter was connected with a closed circuit, and the variations in the sound waves at the transmitting end would be reproduced at the receiving end.

This completed the evidence for the defence.

On Monday Mr. PLUMPTRE summed up the case for the defence, dealing with both the tension regulator and the diaphragm. He especially insisted that the plaintiffs' contention that, so long as a substance separated some-

Digitized by Google

thing from something else and was capable of vibration it was a diaphragm within Edison's description, was untenable. Edison described in substance the mouthpiece and base, and what corresponded to the wooden back board of the defendants' transmitter, which the plaintiffs contended were, each and all taken together, a diaphragm, yet he in no way claimed those parts specifically; on the contrary, he described and claimed as a diaphragm something which was not used at all by the defendants, namely, a disc of mica inside the mouth-trumpet, and adjusted against the tension regulator. Experiments had shown that the defendants' tension regulators would act without any assistance except the current of electricity and the voice itself.

The ATTORNEY-GENERAL, in reply, submitted that the decision of the case must depend upon his lordship's view of the evidence. He drew attention to the fact that no attack had been made by the defendants upon the validity of Edison's patent, and pointed out that what they had attempted was to put a narrow construction upon Edison's description of and claim for the diaphragm. But it must be borne in mind that Edison's invention was in fact at the date of his patent a revelation in a particular branch af science, and what he did was either to discover new functions or a new adaptation of old functions. It would not be reasonable to expect him to have guarded in his specification against every possible adaptation of the principle of his diaphragm; but having discovered a new mode of manufacture he had described its esssential features, and the best mode of carrying it into effect. And it was impossible to adopt the essentials of that new mode of manufacture without infringing it, protected as it was by a valid patent. The specification of Edison showed that he never intended to confine the diaphragm to the special combination to which defendants' witnesses attempted to restrict it. It was not necessary to ask for a beneficent construction of the specification; Edison was describing the instrument by its functions. The defendants' instrument was one in which, to adopt the definition of Mr. Justice Fry, there are parts which separate the substance below from the air or substance above, and those parts perform the functions of Edison's diaphragm, and it was not disputed that it made no difference on the issue of infringement whether the diaphragm, whatever its form, was placed before or behind the tension regulator in relation to the voice. The learned counsel then pointed out that it was misleading to say that Edison used the term diaphragm in a special "telephonic" sense. What he did was to describe the diaphragm as adapted for telephonic purposes. Further, the evidence showed that the shape of the instrument was only a question of degree, and the same might be said of the material and the position. He unhesitatingly submitted that the cone and base of defendants' instrument was in every sense a diaphragm, and that was shown by their acting as a transmitter when merely used as a "toy telephone" or "lovers' telephone," with a piece of string and no electric current. As for the wooden back board, it operated as clearly as anything possibly could, to take up the vibrations of the voice. The use of a transmitter with those features was clearly an infringement of Edison's patent, so far as concerned its first feature of a diaphragm. As to the tension regulator, the defendants had in that respect also been guilty of infringement. Its function was to vary the amount of resistance to the electric current by greater or less surface contact, which may be done by contact, pressure, or compression, or all three, or any two of them. The defendants made use of the same means, but called it "mircophonic contact." Further, there was a concensus of opinion among the witnesses as to the mode of action of the tension regulator. Then it could not be contended that the use of hard carbon in the tension regulator was not included in Edison's invention. The defendants said they used hard carbon and that Edison used compressed plumbago, but it lay upon them to show that it did not act as Edison's compressed plumbago acted. Further than that, one of their own witnesses had admitted that compressed plumbago was in fact compressed carbon. Lastly, he submitted that the defendants' transmitter had been amply proved to be a combination forming a mechanical instrument which acts by picking up and sending on the sound waves exactly in the same way without any material differences as Edison's invention.

At the conclusion of the Attorney-General's speech his lordship reserved judgment.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The twenty-sixth half-yearly ordinary general meeting of this Company was held on Thursday, July 16th, 1885, at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq., M.P.

The notice convening the meeting and the minutes of the last general meeting having been read,

The CHAIRMAN said: Gentlemen, you have had the report in your hands for some days, and I presume you will, as usual, take it as read. But, before moving the resolution approving the report, I shall make a few remarks as I have generally done on these occasions, and though, on the present occasion, your report is very full and complete in every respect, both in its accounts and in the paragraphs which give you information as to what has been done during the half year, still I will keep up my old custom and give you a more general review of the last six months' working of the Company. The revenue for the last six months, ending March, 1885, amounted to £371,682, as against £345,156 in the corresponding period of last year. This increase of £26,526 was owing, no doubt, to the large number of Press and Government telegrams sent in consequence of the military operations going on both in Egypt and India and the war between France and China. The total working expenses amounted to £91,599, against in the corresponding period of 1884, £90,482, or an increase of £1,117. The principal items showing increases and decreases are as follows: The general expenses in London have decreased by £1,085; the working expenses at the stations have increased by £2,959. The details of the various increases and decreases under this head are as follow:—Salaries and wages at stations increased £2,408. We have opened out four new stations during this period, namely, Perim, Piraeus, Patras, and Katacolo. There is also a full six months' charge for working the Suakin station against only four months in the same period of 1884. The repairs and renewals of furniture at the stations show an increase of £961. We have been obliged to take larger offices at Gibraltar to provide for the proper accommodation of the staff there, which was previously insufficient, and I may mention that we make Gibraltar to some extent a station for perfecting our young operators in the work which they are required to perform at the different stations in the Levant, or in the far East, if necessary. There are also several amounts in connection with different stations in the shape of furniture, &c., which make up the amount of increase mentioned. The repairs to stations have increased by £208, principally also at Gibraltar. There is a new office, and probably it is one of the best buildings in Gibraltar, and it had to be fitted up. In medical attendance there is an increase of £54. Rations and provisions show an increase of £226. But this was exceptional. We found at Suakin, where there was so much difficulty in obtaining food, and so much demand for the work, that it was absolutely necessary that we should feed our young people well, and keep them in such a state of health as to enable them to perform the onerous duties put upon them during the time of the operations there. In these days of progress, and being so closely associated with electricity, we have thought it well to introduce the electric light into our station at London, and that has cost us £362. We find where headwork is so absolutely necessary as it is in our operations, that it is most desirable, especially in small rooms, that we should have the air kept as clear and pure as possible, and we believe we can do that much more efficiently with the electric light than with gas. You see, therefore, that we lose no opportunity—in fact, we avail of every opportunity—to give efficiency to our system by keeping those who manipulate and carry on the work in as good a state of health as we possibly can. There are, on the other hand, some decreases in the following items:—Travelling expenses, £382; rent, fuel, and light, £175; expenses of land lines, £1,002; stationery and printing, £194. I may mention that the items of the use of patents, electricians' retaining fee, proportionate cost of Suez-Benha land line, and the construction of cable tanks at stations are the same. But I am glad to tell you that about this period the patent rights of certain patents we have been using—such as the "Mirror," and the "Recorder,' and other inventions of Sir William Thomson, who has been receiving during the last fourteen years, at least, a very handsome income from them—are about to expire, if they have not already expired. That will cause a reduction in our expenses of £3,000 per annum. But, in bidding good bye to these patents, I may say that we, and, in fact, the world at large owe a great debt of gratitude to Sir Wm. Thomson for those inventions, because they have enabled submarine telegraphy to be carried to a point which, I believe, would not have been possible without these inventions. I believe in the early stages of submarine telegraphy that had not the "Mirror" patent been invented by Sir Wm. Thomson, we should have been in darkness so far as the commercial working of that system was concerned. Therefore, while I part from him with the greatest possible pleasure, I would say that we are deeply indebted to him for the benefits we have derived from his great and grand intellect. There are a few other items that I have now to draw your attention to. There is one very important question, and that is the expenses attending the repairs and renewals of cables. They cost last half year £44,815, against £37,113 in the corresponding period of last year, being an increase of £7,702. The question of repairs has always been an important one; and, as our cables are naturally growing older, it must become still more serious. But we have tried in the conduct of this business to maintain our system in as efficient a mode as it was possible for us to do. We have duplicated a very large extent of our system, and we have done a great deal of that duplication and all the repairs out of revenue. That supplies us at the present moment with a very efficient system, but one at the same time which requires not only constant care and attention, but additional ships so as to enable us to have those ships placed at the proper stations in order to avail ourselves immediately of their services for effecting any repair, because, as you know, we are dependent for our income entirely on the maintenance of our system. If we can maintain that system what I would call consecutively—that is, so that there should be no interruptions to the traffic—we find that the use of submarine telegraphy grows steadily and rapidly in a time of good trade, or in a time of any disturbance, or war, or scare. To meet these requirements we must, therefore, not only have our system efficient in the way of duplications—or, I would say, triplications—but also by efficient ships on the spot, so as to do work if it is necessary. It will be seen on reference to the full details in abstract "C" that the work done by our ships has been very considerable. After charging all expenses, including income-tax, providing for interest or debentures, debenture stock, and preference shares, we are enabled to pay a dividend of 5 per cent, which, with the bonus, will make 6 per cent. per annum, and carry forward £100,000 to the reserve fund, against £65,000 at the corresponding period of 1884. On the other hand, we have written off these funds the discount on the issue of 4 per cent. mortgage debenture stock. That you will see is a very important item, and gave rise to a very considerable amount of discussion. But we thought it was better that it should be wiped off at once, so as not to saddle perpetually our income with it. The general reserve fund now amounts to £397,272, and the total reserve fund, including the Sardinian cable and other special reserves, is £431,705. I stated very fully when I last addressed you the percentage that this bore to the capital. I will not go into that matter

Digitized by Google

to-day, but I may take an opportunity of doing so on another occasion, when we have tested the thing more than we have done yet. I may, however, state for your information that in 1877 we took £100,000 from the reserve fund in reduction of the cost of new cables; in 1878 we took £13,997, in reduction of the cost of renewals; in 1884 we took £300,000, towards the cost of new cables; and in 1885 we took £28,105, discount on the issue of 4 per cent. debenture stock, making a total taken from the reserve fund of £442,102. That amount we have applied to maintaining our system. But if we had kept that money in the reserve fund we should now have, instead of £431,000, nearly £900,000 in reserve We think, however, that we have done wisely in the course we have pursued, as it has enabled us to rather increase our traffic, and therefore maintain our dividends, as we now announce to you to-day. I referred in passing to the fact that some of our cables were getting old, and that during active times it was absolutely necessary we should maintain our system in a thoroughly efficient manner. Two or three months ago, as you are aware, there was an important scare, which I believe involved the late Government in an enormous expenditure. That was supposed to subside, and we were getting into smooth water again, and they were paying off forfeits in respect of many engagements into which they had entered. Only yesterday, however, there was another scare, which had a very serious effect on the stocks on the London market. How far that scare may have been justified or not I do not know, but it was a scare, and popular opinion seems to be on the side of the statement which caused it being a correct one. It is not my province here to give any opinion on political matters, but our position is to be prepared for scares, come when they may, and that we should have our system such as to meet the requirements of the Government, and at the same time add to our income by taking advantage of those scares. Therefore, I am going to shadow out to you to-day what we propose doing. We have now a duplicate system between Lands End and Malta. We go to Lisbon, Gibraltar, and Malta. Gibraltar and Malta are two very important strongholds in the Mediterranean. When we get to Malta we have many departures at that point, and we think above all that we should have that system thoroughly efficient. We have put by this time a very considerable amount to the reserve fund—£100,000; and that important income has come more, perhaps, out of those scares than out of legitimate traffic, which has not been so great during the last twelve months—our Indian traffic—in fact, in the last two or three years. But we are going through a cycle of bad times, and we are expecting a cycle of good times, and they will come soon when these scares cease. What we intend now is to triplicate our line to Malta, and then we shall consider ourselves in a most safe and sound position. I believe this will cost over £300,000, but I believe we can do the work partly from the reserve and partly from other sources in a way which will make our present position more stable and more permanent. I think we had better now continue for a time paying you a 5 per cent. dividend, with a bonus of 1 per cent., and strengthen our position so as to make it almost impregnable, than to pay you 7 or 8 per cent. now, and 3 or 4 per cent. next year. I put forward these views to-day because I think it is right that we should make our shareholders aware of our policy. We have a definite policy, and I think it important that both Governments and companies exercising such power as we ought to have a definite policy. We put our policy before you, and in that way enlist your confidence, sympathy, and support, in carrying out the work which we have to do. I show you that this triplication has become almost a necessity; but you will see it more when I tell you that at the present time we have the following breakages, which need not alarm you very much, because the arrangements we have made enable us to earn our income pretty much as if those breakages did not exist. The cables which are interrupted at present are the direct Porthcurno-Lisbon, the Gibraltar-Lisbon, the Suez-Suakin, the Suakin-Perim, and the Bombay-Aden (No. 1). I have never on any previous occasion stated to you the number of breakages, but still our traffic is going on by the arrangements which we have made, and probably a week hence we shall be able to report to you that all these cables are in working order again. We have the business thoroughly in hand. We know where the breakages are, and through the arrangements and efficiency of our ships we are able very promptly to carry out the repairs. These breakages have occurred since you had the report in your hands. Since I last addressed you we have closed a very satisfactory arrangement with the Greek Government, who are probably more in advance than any other governments that we have to do with in the establishment of submarine telegraphy. No doubt that is owing to their island kingdom, and they consider this necessary. We have just completed an arrangement with them for 34 years, that will give us £6,500 per annum upon an expenditure of 447 miles of cable.

A SHAREHOLDER: On an expenditure of how much?

The CHAIRMAN: The expenditure would be about £60,000, or £70,000, but a great deal of that cable is cable that we have more or less. In the course of our repairs we take it up and recast it, and we have always an amount of cable in that way which we can apply without saddling the capital. We are now dealing with Turkey, and probably before I address you next year we shall be able to say that we have made an arrangement with the Turkish Government for an extension to the Arabian ports of the Red Sea. We have done a great deal of work lately, and pleasant work too. Speaking of crazes, a great craze has come up on the part of Germany and France to possess colonies. They seem to look on the West Coast of Africa as a sort of Paradise, from the kind of quarrel which took place about it, instead of its being in the opinion of men who know the coast hardly a place where civilised men would stay to earn a livelihood. It has become notorious that the Government of Portugal has invited tenders for a cable to the West Coast of Africa. Our country—England—which has perhaps more important interests there than any other country, has been obliged to follow suit, and I hope we shall be able to report shortly that we have made an arrangement with the English Government to carry a West Coast cable from St. Vincent to the Cameroons, and probably further. But the inducements to carry it further are not yet very great. The Cape Colony have offered a subsidy which you may have seen in the newspapers, but it is not a subsidy which is likely to bring about an extension of cable to the point they aim at. As to the East Coast of Africa cables, we have had a curious experience. We have referred to it in the report. Curiously enough, since that line was established, we have had every year an interruption in the section from Zanzibar to Mozambique, much about the same time and much about the same place. It would seem to arise from some natural cause, which we could scarcely realise. But the result of our experience has been that we are now satisfied of the cause. Two great rivers run into the sea at that particular point, and we have found that the great rush of water from them undermined the land where the cable lay at the bottom of the sea at that point. Our cable left its resting place, and a break always occurred at the time of this flood. We are therefore duplicating that section of our cable, so as to satisfy the people of the Cape, who pay us a very handsome subsidy, and in order to satisfy the telegraph public generally, whose interests we consider almost first, and thus enable us to secure their traffic, and their confidence and support. That will cost us—or, rather the South African Company, in which we are large shareholders—about £120,000. I mention this because we are really the interested parties, and it will show you that we lose no opportunity of meeting the requirements of our customers. That £120,000 is to be paid out of the reserve of the South African Company, so it does not in the slightest degree reduce our dividends. I think I mentioned in the course of my remarks that we are indebted to the war both in China and Egypt for some of our earnings. Our colonies are so loyal, and so anxious to know what is going on here that when there is anything like a warlike movement in England you would be surprised how it quickens the desire on the part of our colonies to have telegraphic news. I am glad to see that, as it draws us closer to our colonies, and shows that we have a great field there, which we shall carefully try to develop. I think I have pretty well exhausted all I had on my notes, excepting this, that on the 10th of next month a conference, which is held every five years by the Governments of Europe, and indeed by the Governments of all the important centres of commerce and civilisation in the world, will take place; and they send to Berlin delegates to discuss the question of submarine and land telegraphy. The time has not yet come when they admit us into their counsels beyond the fact that we have one representative, I think; but we have found them upon the whole fair and reasonable. The delegates are open to our suggestions and our statements. Wherever we can show that anything we want done is in reason, we find they are disposed to support us. But there is a feeling abroad at the present moment, more particularly in Germany, headed by the Telegraph Minister there, a man of very great intelligence, and occupying a very important position, that submarine telegraphs should be more or less subordinate to the views and actions and policy of the land lines, and his idea is to have a universal system and a very low tariff throughout Europe—an idea that would not quite suit us. We have only to get the two questions fairly considered—the cost of a land line, and the cost of a submarine system—and we shall try and impress on our representatives there from England, who, I have no doubt, will take our view, and also to impress on the representatives of other nations our views, and endeavour to get them to deal justly and fairly by us. We hold that the land system, grand as it is, does not connect them with the world at large. We are the parties they are mainly indebted to for that, and we are entitled to the highest consideration from them. I am hopeful that we shall be successful, but if not successful in getting all our own way, it is still further necessary to triplicate our system. If you are to get a less tariff we must increase our system so as to enable us to carry the messages at reduced rates. This is a summing up probably of what I have said about our duplications, our triplications, and our ships. Altogether I wish you to understand that we are quite alive to the responsibility which rests upon us to maintain this system of submarine telegraphy, which we believe has done a very great deal already to revolutionise the world, and we hope to carry it still further in revolutionising the world still more for good. I now beg to move the following resolution:—"That the printed report "and accounts of the Directors to 31st March, 1885, submitted "to this meeting, be and the same are hereby received and "adopted; that a dividend on the Preference shares of the Company to "the 30th June, 1885, at the rate of 6 per cent. per annum be paid, less "income tax; and that, in accordance with the Directors' recommenda-"tion, a dividend be and is now declared of 2s. 6d. per share with a bonus "of 1s. per share, both free of income tax, on the Ordinary shares of the "Company, making, with previous payments by way of dividend on "account, a total payment of 6 per cent. on these shares for the year "ended 31st March, 1885."

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: Before I put this resolution to the meeting, if any gentleman desires to ask any question of me I shall be glad to answer it before I ask you to approve of the resolution. No one rising to address the meeting, the resolution was carried unanimously. The Chairman further said: I think that closes the business of the meeting, gentlemen, and probably it is the first meeting that we have held at which we have not heard a suggestion. I like to hear suggestions, but we must suppose your silence is an approval generally of the policy of your Board.

Mr. MUIR: Before separating I would propose a vote of thanks to the Chairman and Directors for the way they have conducted the affairs of this great Company. I am sure you will all approve of that.

Mr. HURST: I wish to second the motion. I am very pleased to see the reserve fund standing so satisfactorily as it does, and I have no doubt that judiciously managed as our concern has been hitherto we shall still go on and become even a more flourishing company. We thought some

Digitized by Google

years ago that we should do a great deal if we realised 5 per cent., but we have now gone on to 6 per cent., and the probability is that if we go on as we have done a still further increased dividend may be obtained, and the Company will still go on prospering.

The SOLICITOR (Mr. Burt) put the resolution, which was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I beg to thank you for this renewed evidence of your confidence, and I hope we shall continue to deserve it on all future occasions.

The proceedings then terminated.

The India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The half-yearly general meeting of this company was held on Tuesday, at the Cannon-street Hotel, Mr. S. W. Silver in the chair.

Mr. TYLER (the Secretary) having read the notice convening the meeting,

The CHAIRMAN said they might consider that their sales were up to the average. They were certainly indebted to their indefatigable manager and excellent staff for the amount of business they secured. The portion that fell to their lot he believed was a fair one. Whether at home, on the Continent, or in the colonies they were well represented. As regarded cable sales, the returns at the end of the year would show a fair amount. They had in hand just now a contract for the Indian Government for 500 miles, which they would complete in the course of a month or two. One of their steamers had been employed in laying and relaying cables in the Gulf of Mexico, and another had been chartered by the Government for use in the Red Sea. With regard to the increased capital the new shares were taken up immediately, and he need not say that the capital had been serviceable to the Company. He moved the declaration of an interim dividend of 5s. per cent. or 10s. per share, free of income tax, payable on and after the 22nd inst.

Mr. NEIL BANNATYNE seconded the motion, which was carried.

A vote of thanks to the Chairman and Directors terminated the proceedings.

Anglo-American Telegraph Company (Limited).

Report of the Directors to the half-yearly ordinary general meeting of the proprietors, to be held at the City Terminus Hotel, Cannon-street, London, E.C., on Friday, the 31st inst., at 12 o'clock noon precisely.

The total receipts from the 1st January to the 30th June, 1885, including a balance of £1,676. 14s. 8d. brought forward from the last account, amount to £142,256. 19s. 4d. The traffic receipts show a decrease as compared with the corresponding period of last year of £92,730, consequent upon competition, a reduced tariff, and continued depression of trade between Europe and America. The total expenses of the half year, including repair of cables, &c., as shown by the revenue account, amount to £51,913. 13s. 9d. The Directors, under the powers conferred upon them by the Articles of Association, have, before declaring the nett profits, set apart the sum of £50,000 to the renewal fund, leaving a balance of £40,343. 5s. 7d. One quarterly interim dividend of 4s. per cent. on the ordinary stock, and of 8s. per cent. on the preferred stock, was paid on the 1st May, 1885, absorbing £14,000, and a second quarterly dividend of 6s. per cent. on the ordinary stock, and 12s. per cent. on the preferred stock, will be paid on the 1st August, 1885, absorbing £21,000, leaving a balance of £5,343. 5s. 7d. to be carried forward to the next account. The Company's repairing ss. "Minia" has been engaged during the past half year in the repair of the main cable of the Direct United States Cable Company, and the main cable of the Paris and New York Telegraph Company. She is now at work upon the repair of the Western Union Telegraph Company's cable (broken off the Great Bank of Newfoundland), having been chartered to that company for the purpose. The "Minia" has also restored communication upon the Brest-St. Pierre cable, laid in 1869, which was broken at 240 miles from the French coast. The Company's four main cables are in good working order, but the Duxbury cable, Northern Placentia, and Island Cove cables are all broken in shallow water. The interruption of communication upon those cables, however, does not interfere with the prompt transmission of the traffic, as alternative routes exist. The stockholders will have seen from the official reports circulated by the Company of the proceedings at recent half-yearly general meetings, that the Directors have been severely criticised and strenuously opposed on account of the policy adopted by them some years ago (with the full knowledge and sanction of the stockholders), of placing an annual contribution of £150,000 to the credit of the renewal fund, in order to provide for the replacement of the cables as and when they are worn out. In order to absolve the Directors from the charge of having needlessly deprived the stockholders of dividends, fairly and honestly earned, it has been thought desirable to explain the reasons which have induced the Board to adopt a policy which has latterly met with so much opposition. Without any technical knowledge of submarine cables, it must be obvious to all that from the hour of submersion they are subject to special depreciation, and consequently that the duty of the Directors of such undertakings is to ascertain, as far as practicable, the number of years the cables are likely to last, and to make reasonable provision for their renewal. For many years previous to the amalgamation in 1873, the position of the various companies was so uncertain, and the experience of submarine cables so limited, that the accumulation of a renewal fund upon any fixed principle was impossible, and it was not until after that date that the present system was commenced, and consequently, in order to make up for lost time, a much larger annual sum has hitherto been necessary than would have been required had the accumulation commenced from the date the cables were submerged. The amount which appears to the credit of renewal fund in the present half year's accounts is £788,331. 18s. 3d., and the Directors, having again carefully considered the matter, have come to the conclusion that unless some extensive replacement of cables becomes necessary in the meantime the contribution from revenue to that fund during the current year and the two following years may be taken at £100,000, instead of £150,000 as heretofore, and they trust that after the expiration of that period a still further reduction may be made. The proposition made at the last general meeting by one of the proprietors that the interest of the fund should be paid by way of dividend, cannot be adopted, as the amount set aside in each year has been based upon the principle of a sinking fund, which necessarily includes compound interest. The reduction of tariff to 1s. 8d. per word, commenced on the 24th December, 1884, in consequence of the opening of the Commercial Cable Company, still continues in force; the result is that none of the companies engaged in carrying telegraph traffic across the Atlantic are earning any substantial dividend.

The Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the year ended 30th June last, to be presented at the twenty-eighth ordinary general meeting of the shareholders, to be held at the Company's offices, 61, Old Broad-street, E.C., on the 29th inst., at one o'clock precisely.

From the statement of accounts it will be seen that the gross receipts (including the tax returned by the Spanish Government and the balance brought from last account) amount to £21,447. 0s. 3d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the amount expended on cable repairs) to £6,136. 2s., leaving a sum of £15,310. 18s. 3d. to the credit of revenue account. Of this the sum of £3,500 has been added to the reserve fund, increasing that fund to £65,000. After providing for the preference dividend a balance of £8,810. 18s. 3d. remains, out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 10 per cent. per annum, free of income tax, which will absorb £8,000, and leave £810. 18s. 3d. to be carried forward to the current half-year's account. The Directors have much pleasure in reporting that all the cables have continued in good working order, excepting one of the Santiago Harbour lengths, which underwent some slight repairs in February. The Director who retires from the Board at this time is Mr. Neil Bannatyne, who, being eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor, also retires, and offers himself for re-election.

NOTES.

NOTICE OF REPAIR. — Telegraphic communication with Suakin is re-established.

THE TELEPHONE IN RUSSIA.—We hear that a considerable impetus is to be given to the telephone industry in Russia.

THE SUBMARINE TELEGRAPH CABLES BILL.—In the House of Commons on Monday last this Bill was read a third time and passed.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 24th inst. were £2,687.

THE POST OFFICE TELEGRAPHS.—The telegraph wires at Rood Ashton, Wiltshire, are being extended from Yarnbrook to the residence of Mr. W. H. Long, M.P.

NEW CABLE.—A telegram dated Paris, July 23rd, says that the Chamber of Deputies have passed the Bill for laying a telegraph cable between Senegal and Gaboon.

THE PERSIAN TELEGRAPHS.—The Persian Government intends constructing a telegraph line between Meshed and Sarakhs. The greater part of the necessary material is ready.

DEATHS BY LIGHTNING.—During a violent thunderstorm on the 22nd at Torre Cajetani, a small market town in the neighbourhood of Anagni, thirteen persons were killed and twenty-two severely injured by the lightning.

A NEW ELECTRIC RAILROAD.—St. Louis is to have an electric railway ten miles long. The system to be used is that of Dr. Wellington Adams, and a company has already been formed in Missouri to carry out the work.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending the 25th inst. were £2,155, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE EARTHQUAKES.—Three shocks of earthquake have occurred in Rungpur, Bengal Presidency, causing serious damage. A village near Nattore has sunk completely into the earth. A Reuter's telegram, dated Smyrna, July 30th, says that two successive shocks of earthquake were felt there shortly before six o'clock on the morning of that day.

THE LONGITUDE OF SENEGAL.—The result of the observations recently carried out with the object of determining the difference of longitude between the observatory at San Fernando, the Canary Islands, and St. Louis du Senegal is that the latter place is 1h. 6min. 2sec. west of San Fernando. Other computations have not transpired.

COUPLING BY ELECTRICITY.—The Louisville *Courier Journal* gives an account of a South Carolina genius who claims to have invented a perfect system of car coupling by electricity. Upon a recent trial a luggage train, it says, was in four pieces and coupled up without the aid of any person except the guard, who did the entire work from the brake van.

THE INTERNATIONAL TELEGRAPH CONFERENCE. — Mr. Floyer has left for Berlin to represent Egypt at the International Telegraph Conference, which will probably be opened on the 10th August. The first question for deliberation will be the propriety of introducing a uniform international tariff, a measure which is especially desired by Germany.

ANOTHER WONDERFUL BATTERY.—Messrs. Kauffer and Goldner, of Boston, U.S.A., have, it is said, succeeded in producing a battery of nine cells, which will light two 8 c.-p. incandescent lamps for 150 hours out of 300. The lamps have, we are informed, been burning more than a third of that time, and as yet the cells show no signs of being exhausted.

OUT OF IT.—Recently in Philadelphia an old woman drank a wineglass of battery fluid composed of sulphuric acid, sulphate of copper, and bichromate of potassium in mistake for a dose of tonic bitters. The internal resistance of the unfortunate woman not being equal to the E.M.F. of the battery, the result was a break of continuity, for which in this life there is no remedy.

A LOCOMOTIVE STRUCK BY LIGHTNING.—A singular accident recently happened, says the *Scientific American*, at Milnes, Va., on the Shenandoah Valley road, when the locomotive of a freight train which was standing on a siding was struck by lightning. Both the engineer and fireman received severe shocks, the engineer being so injured that he did not recover for several days, and the engine was somewhat damaged. Accidents of this kind rarely happen.

THE FRENCH TELEGRAPHS.—The French Minister of Posts and Telegraphs has authorised the establishment of telegraph offices in the following communes:—Castlenau d'Estretefonds, Saint-Jory (Haute-Garonne); Saint-Août (Indre); Gizeux (Indre-et-Loire); Villemontais (Loire); Frayssinet (Lot); Gesté, Jallais (Maine-et-Loire); Marinviller (Meurthe-et-Moselle); Cercié (Rhône); Aillevillers (Haute-Saône); Romenay, Saint-Julien-de-Civry (Saône-et-Loire); Courlon (Yonne).

AN IMPROVEMENT.—After the 15th of September next the electric light apparatus in the lighthouse at Cape Griz-Nez, which gives an alternate white flash and eclipse of 30 seconds' duration, will be replaced by a larger apparatus flashing three white rays and one red ray. The three white rays will be arranged so as to follow each other with great rapidity, there being an interval of about 12 seconds after the third flash, and in the middle of this—that is to say, at the sixth second—the red flash will appear.

"—— MELANCHOLY, SLOW."—Who is responsible for this? A telegram was handed in on Tuesday last at one of the metropolitan stations of the Post Office Telegraphs for despatch to a suburban locality some five miles distant. This was at 1:40 p.m., and the message did not reach its destination until seven minutes past eight on the following morning. If that is the way the Post Office transacts its business under the conditions of the present tariff it had better leave sixpenny telegrams alone.

ELECTRIC HEAD-LIGHTS IN AMERICA.—The Lehigh Valley Railroad has contracted for the equipment of its engines with electric head lights, subject to certain tests that are to be made between Easton and Jersey City at an early date. The dynamo is run by a small engine of 1½ horse-power, attached to the side of the regular boiler, and fed by it. The invention is a Western one, manufactured and controlled by a company in Ohio. It is already in operation on the Pan-Handle Railroad west of Cincinnati.

ECOLE SUPERIEURE DE TELEGRAPHIE.—In conformity with the decision of the Minister of Posts and Telegraphs given on the 22nd inst., l'Ecole Supérieure de Télégraphie will be opened in Paris, Rue de Grenelle, Saint Germain, on the 22nd of next September. Applications for admission to the courses to be addressed to the Minister of Posts and Telegraphs before the 1st day of that month. The *Journal Officiel* of the 25th inst. publishes in full the conditions and regulations under which admissions are granted.

BOOKS RECEIVED.—"Electricité a L'Exposition Universelle d'Anvers," par Charles Mourlon, No. 1; "Bruxelles Imprimerie du Mouvement Industriel. Well got up, and well worth

Digitized by Google

reading. M. Mourlon has commenced his task in the right way, and by clear, though somewhat brief descriptions of the Ochorowitz microphone, the Van Rysselberghe system of simultaneous telegraphy and telephony, the Redon call bell, and other useful inventions of comparatively recent date, has made up a very readable number.

THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.—Notice is given that the second annual general meeting of the Edison and Swan United Electric Light Company will be held at the Holborn Viaduct Hotel, London, E.C., this day (Friday), 31st inst., at 1:15 in the afternoon, for the purposes following, namely:—To receive and consider the annual statement of accounts and balance-sheet, and the report of the directors and auditors thereon; to elect directors and auditors, and transact the other ordinary business of the company.

OBITUARY.—The death is announced of Mr. Gower, inventor of the telephone which bears his name. Mr. Gower left Cherbourg on the 18th inst. in a balloon, for the purpose of carrying out some experiments having for their object the perfection of a device for obtaining automatically a desired equilibrium of the balloon at different altitudes. The balloon, however, descended when some distance at sea, and the unfortunate gentleman, after floating for many hours, ultimately died from cold and hunger. The balloon was found by some fishermen several miles from Dieppe.

LIGHTING OF ASSURANCE OFFICES. — The Prudential Assurance Company have entrusted the lighting of their offices in Holborn Bars to the Electrical Power Storage Company, of 4, Great Winchester-street, E.C. When completed this installation will consist of 1,500 lights of 20 candle-power, and will be one of the most complete in existence, as in addition to the storage batteries—which will be capable of working the lights for ten hours—the Marshall engines will be powerful enough to drive all the lamps direct. Three multitubular boilers, each of 45 horse-power, will be fixed, and two horizontal engines.

UNDERGROUND WIRES IN AMERICA.—We are informed that the President of the Baltimore and Ohio Telegraph Company, July 1st, signed a contract with the Averill Insulating Conduit Company for placing the wires of the company underground. The work will be begun in Washington immediately. The insulating material in which the naked wires are to be laid is composed of pure silica and refined asphaltic cement. From experiments already made it has appeared that 1,600 wires can be laid to the square foot, the insulation being so perfect that the strength of four dynamos was not sufficient to affect it.

THE LIGHTHOUSE COMMISSION.—In the House of Commons recently Lord C. J. Hamilton asked the Vice-President of the Board of Trade whether Her Majesty's Government have had under their consideration, in the interests of science and of the maritime welfare of the country, the advisability of requesting Professor Tyndall to resume the position he recently occupied in connection with the Lighthouse Commission. Baron H. De Worms, in reply, said that in March, 1883, Professor Tyndall resigned the office of scientific adviser to the Trinity House, the Commissioners of Irish Lights, and the Board of Trade. He had made no application to be reinstated in that position.

A TELEGRAPHIC SCANDAL IN FRANCE.—At an electoral meeting at St. Die, in the Vosges, M. Charles Ferry, brother and fellow deputy of the late Premier, was roughly handled by M. Tony Révillon about Tonquin, and hissed when he said it was above all things necessary to have such a colonial policy as would checkmate England. M. Charles Ferry's report of the meeting representing himself victorious reached the *Temps* the same evening, but the despatch of M. Tony Révillon's friends to the *Justice* was delayed forty-eight hours. M. Révillon threatens an interpellation on this subject, but suspends it on the promise of M. Sarrien, the Postmaster-General, to make a searching inquiry. It would appear that M. Ferry's partisans are still powerful in the Vosges telegraphic offices.

ELECTRIC LIGHTING AT MARLBOROUGH HOUSE ON JULY 24. The total number of lamps fixed was 340, of which 280 were of 20 candle-power, in frosted globes, and 60 were of 10 candle-power. In the ball rooms some of the lights were attached to the existing candelabra, and others were fixed round the cornice. In the Indian room 10 candle-power lamps, silvered on one side, were placed inside the cases to illuminate the Indian jewels. The saloon was mainly lit by lamps suspended from the existing fittings, but effect was obtained from a row of lamps placed out of sight at the foot of the pictures. The lamps in the conservatory, music rooms, and passages were placed in tinted shades. The whole of the current for the lamps was supplied from accumulators placed in a tent in the garden. This is, we believe, the largest temporary installation which has yet been worked in England from accumulators, the cells being brought, ready charged, from the works of the Electrical Power Storage Company at Millwall, a distance of about six miles. The same company carried out the whole of the work.

PROFESSOR BELL.—A Washington newspaper correspondent says:—"Professor Bell, the inventor of the telephone, is a tall, well-formed man of perhaps forty-one or forty-two years of age. He has a big head, well set on a pair of broad shoulders. His forehead is high, broad, and full, and a bushy heap of glossy black hair stands up and back from it as though its owner had the habit of often pushing his fingers through it. He has a pair of velvety black eyes, very bright, and such as I should imagine could fill with the feeling of the soul behind them upon occasion. He has a dark complexion, a strong mouth and features, tending rather to the English cast. He has a slight English accent, talks well, and keeps his mind well in hand. He is a hard worker, and I am told he often works all night long when he has some experiment on hand in which he is deeply interested. Mr. Bell's workshop, or library, is in the top of his big house in Scott Circle. The whole floor seems to be given up to it, and books, telephonic apparatus, and files of papers take up the several rooms of which it is composed. It is a delightfully airy place, and it gets the cool breezes which come from up and down the Potomac."

THE ELECTRIC LIGHT FOR ILLUMINATIONS.—A most noticeable feature in the illuminations with which the festivities at Osborne were terminated on the occasion of the marriage of the Princess Beatrice, on 23rd inst., was the electric installation on board Her Majesty's yacht, "Victoria and Albert." It consisted of a group of one hundred incandescent lamps, arranged in the form of the letter B., surmounted by a coronet, the whole being suspended between the main and fore masts of the yacht. The lamps used on this occasion were obtained specially for the illumination from Messrs. Woodhouse and Rawson at a very short notice, and consisted of their 20 candle-power new filament 46-volt lamps. The electric current for the lamps was supplied by a Gramme dynamo, worked in H.M.'s gunboat, "Bloodhound," which was moored astern of the royal yacht, through electric cables passed between them. In addition to the above most effective device, a powerful naval searchlight of 25,000 candle-power was displayed, its pure

Digitized by Google

beam of white light illuminating at intervals Osborne House, the grounds, and the various ships and yachts in the bay. The whole of the arrangements were carried out by the electric light staff of the Naval Torpedo School ship, "Vernon."

DETERMINING THE WORK OF ELECTROMOTORS.—In determining the working conditions of electromotors, the ordinary plan consists in applying the brake to the motor and varying the load as required. This, however, introduces a source of uncertainty, as the fluctuations which occur when the brake is the absorber of power cause variations of speed, and consequent fluctuating readings in the instruments. In order to overcome this difficulty, and to render the speed of the motor absolutely uniform, Professors Geyer and Denton, of the Stevens Institute of Technology, have devised an ingenious method, which gives excellent results. In order to make the work of the motor uniform, they cause it to drive a dynamo, the current of which is sent through resistance coils, which are kept at a constant temperature by the air circulating around them. This dynamo is mounted on the cradle dynamometer of Professor Brackett, and thus at the same time the power exerted by the motor is accurately measured. We have, therefore, a dynamo generating current for the motor, and a second dynamo as the absorber of power. By merely changing the resistance in the coils above mentioned, the work of the motor can be readily altered to any degree and kept uniform for an indefinite length of time. For testing purposes this method is evidently superior to the brake, and in addition permits of the use of a dynamometer specially adapted to dynamo and motor testing.—*Electrical World.*

THE WEAR AND TEAR OF TELEGRAPH CLERKS.—A London correspondent of the *Edinburgh Evening News* is informed that the estimates for the Revenue Department for the year ending 31st March, 1886, present a curious study, particularly that portion which deals with the pensioning of the telegraph service. "It has long been contended that the constant wear and tear to the ear of the click-click in the telegraph instrument, or what is technically known as sound-reading, exercises a most injurious effect on the brain tissues. Apart from the actual monotony of the ceaseless repetition, the tension of the auricular nerve is a strain bound to tell on any but brains of the toughest fibre, and the pension list just issued clearly emphasises the fact. For example, there are for the twelve months dealt with 34 cases of fresh pensions. Three are granted for old age, *i.e.*, to people over 60; 13 for diseases which are specified by some term which can be understood, such as phthisis or cardiac disease. The remaining 18, however, are described by such delightfully vague terms as mental incapacity, general impairment of health, cerebral anæmia, infirmity of mind and body, nervous exhaustion, nervous prostration, until, fairly worn out for a word which shall signify idiocy, insanity, this is at last boldly stated. It is, to say the least, strange that more than 50 per cent. of the pensions should be caused through de rangement of the nervous system, and it is likely to call for some inquiry."

ELECTRICITY IN MINES.—The Zankerode Electrical Railway was a good beginning in the application of electro-motors to the work of underground haulage. The success of this experiment has led to a further step being taken in the same direction, and we now have an excellent example of an important electrical mineral line. This line is now in operation at the Paulus-Hohenzollern Collieries in Upper Silesia. The line, which is 800 yards in length, has been constructed for a traffic of 500 tons of coal in ten hours. This result Messrs. Siemens and Halske have guaranteed. The electrical locomotive weighs two tons; it is controlled by a specially devised regulator, which is said to give great satisfaction to those in charge of the train by its prompt and certain action. The insulated conductor consists of flat iron bars, galvanised at the ends and connected by means of fish plates. This conductor is suspended from the roof upon insulators. Brushes on the locomotives take the current from the conductor. The line is connected with the generator by cables about 250 yards long. The generator is driven by a belt from the flywheel of the engine. The trucks weigh 10 cwt. each, and have a capacity of 11 cwt. The train is composed of fifteen trucks, so that the useful load hauled is a little over eight tons, and the whole load nearly sixteen tons. With this load a speed of 7½ft. a second is reached. With an empty train the speed is 12ft. a second. At present the output is not sufficient to require the maximum transport of 500 tons a day.

THE ELECTRIC LIGHT AND MICROSCOPY.—At the meeting of the San Franscisco Microscopical Society on 10th June, Mr. Banks gave an interesting demonstration of the electric light in its relation to microscopy. He first showed a miniature incandescent loop lamp actuated by a sulphuric acid and sulphate of mercury battery. For purposes of microscopical illumination, the incandescent electric light possesses the great advantages of extreme whiteness and intensity. With regard to the batteries actuating these lamps, there are still some difficulties to be overcome, but there can be scarcely a doubt that it is a question of only a short time when, with increased steadiness, duration of action, and cheapness of battery power, the electric light will be superior to all other methods of artificial illumination for microscopical and microphotographic purposes. Mr. Banks also showed under the society's largest microscope the electric spark in its passage between the terminals of a ¼in. spark induction coil attached to a Grenet bichromate solution battery. Two vulcanite slides had been prepared, on which were fastened adjustable platinum strips connected with the battery wires, and terminating in brushes of platinum wire of extreme tenuity. The electric fluid, in its passage from one terminal to the other, formed a very attractive object under the microscope. One of the slides was used to show the effect on the electric spark of interposing films of soot of different thickness. In its passage through these the current was deflected into meandering lines, around which scintillated showers of sparks. The particles of soot could be seen arranging themselves in symmetrical groupings around the terminals. In conclusion, Mr. Banks announced that he had sent for, and would soon be able to exhibit the Stokes-Watson apparatus for showing under the microscope the combustion of various metals in the electric arc. Their characteristic spectra can also thus be shown by the micro spectroscope.

ANGLO-AMERICAN BRUSH CORPORATION'S EXHIBIT AT THE ALBERT PALACE.—In continuation of our remarks on this subject we append the following:—The grounds are lit by means of 20 arc lamps, worked in series off a single circuit of wire in conjunction with 44 incandescent lamps, arranged in multiple series of eleven to a group, these latter being used for lighting the band stand. The arc lamps are those of the well-known Brush 2,000 c.-p. type placed on posts at a height of 22ft. above the ground; the incandescent lamps are those of the Victoria type of 20 c.-p., and are arranged inside the band stand, and fitted in coloured glass globes. This apparatus is worked by means of two No. 7 Brush machines, driven by one of Messrs. Robey and Co.'s 12 h.-p. nominal semi-fixed engines. Although this apparatus produces a very beautiful illumination in the grounds, yet it has been thought desirable for ornamental purposes to supplement the arc lights mentioned with 700 coloured incandescent lamps

Digitized by Google

of 5 c.-p. each, which are hung in festoons between the posts which carry the arc lamps, and run on the multiple series system in groups of thirteen, all large and unsightly cables being dispensed with, which is a most important point in places such as this. The type of lamps employed for this illumination are 24 volt 5 c.-p. Victoria incandescent lamps, specially designed and manufactured by the corporation for this purpose. They are variously coloured, and the effect produced is very pleasing, giving complete satisfaction. For working these small lamps a No. 71 Brush machine, with patent laminated armature core, is employed, driven by one of Messrs. Marshall and Son's improved semi-portable engines, fitted with patent automatic expansion gear. The arrangement and fixing of these installations has been carried out under the superintendence of Mr. F. W. Clements, one of the assistant engineers of the Anglo-American Corporation, and reflects great credit on that gentleman's taste and skill.

THE BLACKPOOL ELECTRIC TRAMWAY.—A local contemporary says:—Mr. Holroyd Smith, engineer to the Blackpool Electric Tramways Company, and inventor of the system shortly to come into practical use under their control, has had the satisfaction of giving a genuine demonstration of the working capacity of his patented method. It is quite true that the experimental venture was limited by reason of the incompleteness of the tramway works, but in so far as it was possible to test the line of route available, it was made abundantly evident that the electrical arrangements were quite competent to create a "going concern." The experimental "runs" were made from the Foxhall Hotel to the Wellington Hotel—a stretch of ground in every way suitable to the test from an electrical point of view, but affording a singular witness to the limited character of our conveniences for vehicular traffic. Whether of chance or design, it seemed as though the entire vehicular traffic of Blackpool was concentrated on this one particular spot on the occasion of the experiments, and in view of this fact, as also the number of spectators present, the absence of any accident goes some way towards showing that the electrical motive power is so far under control as to be capable of avoiding risks even under abnormal circumstances. More than one possibility of danger arose during the afternoon, but the rapidity with which the electric car was drawn up averted harm. Mr. Holroyd Smith undertook charge of the car—a handsomely constructed vehicle—and was apparently entire master of the situation. When the work of connecting the car-motor with the generating machine had been completed, a trial trip was organised. In the hands of Mr. Smith the switch proved to be very effective, alternately moving and stopping the car at pleasure. The experiences of the ride were satisfactory in every way. The cars are elegant in design, light in construction, and altogether admirable in the accommodation they afford.

THE TELEPHONE AND FIRES.—In connection with the great fire in Shoreditch on Wednesday last we are informed that the first "call" was received at eight minutes past one o'clock in the afternoon at the Shoreditch station, when the firemen were warned that there was a large warehouse on fire in Holywell-lane. The manual was at once turned out, and the intelligence forwarded to Whitechapel and to Captain Shaw at Southwark. Five minutes later the serious nature of the message was verified by a telephone call from Messrs. De la Rue's premises, which are close by the fire. Four steamers were immediately turned out, and it was found upon their arrival that the building numbered 18, in Great Eastern-street, and occupied by Mr. J. Chessum, a builder, was thoroughly ablaze, and that while workshops, store, and engine and boiler houses had all become involved, the fire was already spreading to the cabinet making premises of Messrs. Fineberg and Friedman, at No. 18A. As it was seen that there were other premises in danger, a telephonic message secured the turning out of two steamers from each district of the metropolis, as well as the headquarters' steamer, and Captain Shaw proceeded himself to the scene in a hose cart conveying hose to the extent of 1,000 feet. In the quarter of an hour which had elapsed, however, in the circulation of the messages, the flames had spread over to the wholesale ironmongery premises of Messrs. Crossman and Co., at 20, Holywell-lane, comprised in a five-floored warehouse of considerable dimensions, and had also attacked two large unoccupied five-floored warehouses next door. Under these circumstances more help was again telephoned for, and this time four steamers from the different districts were ordered, the result being that steamers were on the spot at two o'clock from Southwark, Chelsea, Portland-road, Regent-street, Clerkenwell, Islington, St. Luke's, Scotland-yard, Camden Town, Holloway, Whitechapel, Hackney, Bethnal Green, Mile End, Bow, Poplar, Shadwell, Bishopsgate, Shoreditch, Tooley-street, Rotherhithe, and Waterloo-road.

TELEPHONE CHARGES IN DUNDEE.—Mr. E. J. B. Lowdon, electrician to the late Dundee and District Telephone Company, has written as follows to the *Manchester Guardian*: "My attention has been drawn to the report in your issue of the 10th inst. of a reply made by Mr. Mosley, the chairman of the Lancashire and Cheshire Telephone Company, to the deputation which had waited on the directors to ask for a reduction in the exchange rate. Mr. Provand appears to have urged that the success of the Dundee and District Company, which charged only £10 per annum when it started and £5 afterwards, proved that the Manchester rate of £20 was too high. To this Mr. Mosley is reported in your journal to have replied as follows: 'The work in Dundee was carried out in a way that in Manchester would be considered quite unsafe, and would be at once condemned by the officials of the corporation under whose control they had to work. The lines in Dundee were run in an immense long span, in order to avoid the cost of construction. Permanent ways of poles and standards, which were costly in construction and in maintenance, were not established. They simply ran single wires from roof to chimney in the cheapest and most simple manner possible, and in a way that certainly the Lancashire and Cheshire Company would not lend themselves to.' In reply to the above I have to state that they are altogether uncalled for and altogether untrue. The wires here are as well put up, if not better, than those in Manchester. The position and length of stretch have all to be submitted to the town surveyor, and have to get his approval as well as that of a Committee of Council. Our spans are mostly shorter than those of the National Company, which occupies the same position here that the Lancashire and Cheshire Company does in your city. Our permanent ways will stand as long as any telegraph wires that are put up, and longer than the National's. Our poles are put through the roofs, and not merely laid on and guyed, and there are no attachments made to chimneys in all the system under me."

SIXPENNY TELEGRAMS.—Dr. Cameron, M.P., has written a letter on this subject, in expectation that he may not be able to be present when the Telegraphs Acts Amendment Bill comes on for discussion. He says Mr. Shaw-Lefevre's scheme, with the amendments which he was prepared to accept, would have given us a halfpenny per word tariff, under which groups of five letters or figures would have been reckoned (as in international telegrams) as single words, and the minimum charge

Digitized by Google

would have been 6d. Lord John Manners, after his minimum, proposes the same halfpenny a word, and the sole difference between the two proposals is that while Mr. Shaw-Lefevre proposes to allow the sender to divide his twelve words between address and message as he pleases, Lord J. Manners will only allow him to send three words, or 1½d. of message, and compels him to take out value for the remaining 4½d. in a free address, of which many years' experience has enabled us to predicate the exact average length, and the fact that it will contain a number of absolutely useless words. Dr. Cameron remarks that as, in 1876, Lord J. Manners gave way to a decision of a Select Committee of the Commons, and abandoned the increase of charge then proposed, so he has no doubt but that in 1885 he would yield to an adverse decision of the House, and adopt a well-considered scheme approved by the Department over which he has been called to preside rather than render useless for an indefinite time the capital expenditure of £500,000, and the annual cost of £60,000 for salaries incurred in preparing for the introduction of 6d. telegrams. Dr. Cameron is certain that nine persons out of every ten who compare the competing schemes will decide in favour of that which allows the sender to distribute his twelve words between address and message as he likes, and against one which, while practically giving but the same number of words, imposes restrictions upon them which will prevent their use to anything like the best advantage, and will perpetuate the costly extravagances of the present system, admitted without exception by every practical Post Office telegraphist who has written or spoken on the subject.

Colliery Explosions and Earthquakes.—Now, says the *Colliery Guardian*, when the North of England Institute of Mining Engineers is occupied in tracing the connection between earthquakes and colliery explosions, and the minds of many are turned towards the subject, it will be found interesting to set out some of the facts connected with these natural phenomena that have already been observed. There is a coincidence of time in the occurrence of colliery explosions and seismic disturbances worthy of attention. The researches of Otto Volger have already established this fact. The relative frequency of shocks in winter and in summer is clearly seen in the tables which he publishes, and the difference for the several months of the year is so striking that it cannot fail to suggest, even to the careless observer, a relation to the colliery disasters. Of the 1,230 shocks which have occurred in the Alps during the course of his observations, 774 have happened in the autumn and winter months and 456 in the spring and summer months. These numbers are to each other as 1·69 is to 1. This division, however, does not show the relative frequency of these shocks in the most striking nor in the most instructive circumstances. The number of shocks in spring and in autumn are about equal, but in winter the disturbances are three times more numerous than in summer. Their distribution in the months of the year are as follows:—In January, 150; in February, 143; in March, 138; in April, 119; in May, 58; in June, 54; in July, 40; in August, 47; in September, 117; in October, 111; in November, 85; in December, 168. Volger states that of the 98 shocks which have occurred in Le Valais since 1856, 72 have happened in winter, and only 1 in summer. He remarks further that these disturbances are more frequent between sunset and sunrise than during the daytime. Of the 502 shocks in Switzerland, the exact time of occurrence of which has been recorded, 320 have happened at night and 182 during the day. From these figures it appears that—for that locality, at least—earthquakes are nearly twice as frequent in the night time as in the daytime. To determine this question in a general manner, he has tabulated the shocks which occurred in the two hemispheres in the years 1855 and 1856 of which the times are known. The result is that 300 appear under the head of "night," and 172 under that of "day." Other writers have observed and recorded the same fact for various localities.

The Cape Government and the Proposed Alternative Cable.—On June 26 Mr. Upington moved "That the House go into Committee to consider the motion for alternative cable communication between the colony and England, *viâ* the West Coast." The hon. mover said, in placing this resolution before the Committee, he thought he might fairly state that this was a matter of very considerable importance to the colony, especially considering what had recently taken place. The arrangement entered into with the telegraph company was that the large sum of £15,000 should be paid annually from 1879, as a subsidy, to provide cable communication between this colony and England. Though he had no desire whatever to reflect on this company, on more occasions than one the colony had been left without cable communication for a very considerable period—a longer period, possibly, than circumstances justified. If, at a reasonable expense, they could get a competing company to establish another line it would be a benefit to the colony, as the cost of messages would possibly be reduced by one-third or one-fourth. Furthermore, the advantage of having another line to fall back upon, in the event of one being broken, would be incalculable. The Government was not bound down to negotiate with the particular company mentioned. Some months ago the company communicated with the Government, through the Agent-General, requesting leave to land their cable on the coast, and the Government gave its consent. So far as he could judge—on reference to a chart before him, for the use of which he was indebted to the hon. member for Cradock—the company had already come a long way down the West Coast, and, instead of laying their cable in deep-sea water, seemed to have hugged the shore almost all the way along. Their proposal was to land at Port Nolloth, if any arrangement could be made with the Government, and the advantage of having land communication was greater than some people might think. It would be a great advantage for trade, as then information coming direct from England would not first have to pass through outlying portions of the country. A land line from Port Nolloth would cost from £25,000 to £30,000, and, for the use of this land line, the company might pay 5 or 6 per cent. per annum out of the subsidy granted by the Government. He would propose that the Government be authorised to enter into negotiations with some company for the completion of a West Coast line, with a subsidy of £7,500 per annum. The money so spent, he was satisfied, would find its way back threefold into the pockets of the people of the colony, in consequence of the advantage to be derived from the competition between two telegraph companies. At present the charge for messages was simply prohibitive, and the only way to reduce it was by competition. He would move that the blank in the motion be filled up with the words "£7,500." Sir Thomas Scanlen moved, as an amendment, that the words "with the India Rubber and Gutta Percha Company of Silvertown, or any other suitable company" be omitted. Mr. Jones moved, as a further amendment, that the subsidy be £5,000 which, after discussion, was withdrawn. Sir Thomas Scanlen's amendment was then put and agreed to, and the resolution as amended was put and declared by the chairman to be negatived, whereupon a division was called for, which resulted as follows:—Ayes, 31; noes, 25.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XXVIII.

Rotation of an Armature, taking Self-Induction into account.

The first approximation to the E.M.F. developed by the rotation of a Siemens armature in a uniform field was given in Art. XX., where the armature's own lines of force were neglected. We can now give a more complete investigation, and bring out more clearly the point already noticed in Art. XXVI., that the apparent resistance of the armature is greater during rotation than it is when stationary, a sort of spurious resistance being developed by the effect of self-induction in the commutated coils.

The fundamental relation is, we know, that if N be the total number of lines of force passing through a coil at any instant, the induced E.M.F. generated by varying that number is simply equal to their rate of change,

$$e = \frac{d\,\mathrm{N}}{d\,t}.$$

Now, N really consists of two parts—the lines due to the field, and the lines due to the armature itself; and these last are proportional to the strength of current flowing round it, being equal to $\mathrm{L}\gamma$. The lines due to the field depend on what sort of field it is, but if we consider it a uniform field of intensity F, and take the case of a Siemens armature with its component coils at all manner of angles to the line of force, the value of N is

$$\mathrm{N} = \Sigma(\mathrm{A\,F}\cos\theta) + \mathrm{L}\,\gamma,$$

L being the self-induction coefficient measured from brush to brush.

The rate of variation of the first of these two terms has already been discussed at length (*see* Art. XX.), and has been shown to be, if β is the angle been successive coils of the armature, and ω its angular velocity,

$$\frac{\mathrm{A\,F}\,\omega}{\sin\frac{1}{2}\beta}\cos(\omega\,t - \tfrac{1}{2}\beta)$$

which, for shortness, we will, as before, call E.

This E was the whole E.M.F. when there was no self-induction; but taking the complete value of $\frac{d\,\mathrm{N}}{d\,t}$, we find the actual E.M.F. generated by the rotation to be

$$e = \mathrm{E} - \frac{d}{d\,t}(\mathrm{L}\,\gamma),$$

or writing $\mathrm{R}\,\gamma$ for e, where R is the total resistance of the circuit, external as well as internal,

$$\frac{d}{d\,t}(\mathrm{L}\,\gamma) + \mathrm{R}\,\gamma = \mathrm{E},$$

or writing out the first term more fully,

$$\mathrm{L}\frac{d\,\gamma}{d\,t} + \left(\mathrm{R} + \frac{d\,\mathrm{L}}{d\,t}\right)\gamma = \mathrm{E}.$$

Here, then, we perceive as co-efficient of the current strength γ something more than the true resistance R, viz., a spurious or apparent resistance $\frac{d\,\mathrm{L}}{d\,t}$; and this can only be nothing if L, the self-induction of the circuit, is constant.

But L is not constant in a commutated coil, but is continually increasing, as shall now be explained. When the commutator gap belonging to a coil comes up to the brushes to be short-circuited the current in that coil is steady, and accordingly the removal of the coil from the main circuit effects no change in that circuit beyond a minute fall of resistance, which is quite probably compensated by the simultaneous restoration of a similar coil to the circuit on the other side of the brush. But when a coil is restored to the current again after short-circuiting, a current has to be started in it *de novo*, and so its self-induction entails a clear loss of energy. For every coil which passes the brushes the circuit thus acquires an extra amount of self induction, and in one revolution it acquires the amount L. This goes on uniformly, and so the rate at which the circuit gains self-induction, or $\frac{d\,\mathrm{L}}{d\,t}$, is equal to $\frac{\mathrm{L}}{\mathrm{T}}$ or $n\,\mathrm{L}$; and the above equation becomes

$$\mathrm{L}\frac{d\,\gamma}{d\,t} + (\mathrm{R} + n\,\mathrm{L})\,\gamma = \frac{\mathrm{A\,F}\,\omega}{\sin\frac{1}{2}\beta}\cos(\omega\,t - \tfrac{1}{2}\beta).$$

The solution of this equation is

$$\gamma = \frac{\mathrm{A\,F}\,\omega\cos\phi}{(\mathrm{R} + n\,\mathrm{L})\sin\frac{1}{2}\beta}\cos(\omega\,t - \tfrac{1}{2}\beta - \phi) + \mathrm{C}\,e^{-\frac{\mathrm{R}+n\,\mathrm{L}}{\mathrm{L}}t},$$

where $\tan\phi = \frac{2\,\pi\,n\,\mathrm{L}}{\mathrm{R} + n\,\mathrm{L}}$.

The second term in this equation may be neglected, as only representing initial disturbances which soon subside, and the rest may be written

$$\gamma = \frac{4\,n\,c\,\mathrm{A\,F}\cos(\theta - \frac{1}{2}\beta - \phi)}{\sqrt{\{(\mathrm{R} + n\,\mathrm{L})^2 + 4\,\pi^2\,n^2\,\mathrm{L}^2\}}},$$

c being half the number of commutator segments.

In Art. XX. it was pointed out that the effect of the commutator is to prevent a continuous change of θ; it is only allowed to vary through the angle β; and to get the maximum effect it is plain that the brushes should be set so that it may vary from ϕ to $\phi + \beta$. The variation part of the above expression may then be considered as practically unity, and the total E.M.F. obtained from the machine is

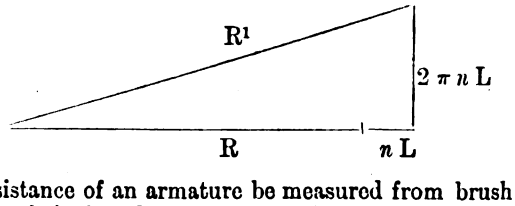
$$e = \frac{4\,n\,c\,\mathrm{A\,F}}{\sqrt{\left\{1 + \left(\frac{2\,\pi\,n\,\mathrm{L}}{\mathrm{R} + n\,\mathrm{L}}\right)^2\right\}}} = 4\,n\,c\,\mathrm{A\,F}\cos\phi.$$

Without self-induction this would have been simply $4\,n\,c\,\mathrm{A\,F}$, or E. But the actual E.M.F. is

$$e = \mathrm{E}\cos.\,\phi,$$

ϕ being the lag.

Instead of thus treating the effect of lag as a diminution of E.M.F., we may equally well regard it as an increase of resistance, and may say that, whereas the resistance of an armature in motion is really to all intents and purposes greater by the amount $n\,\mathrm{L}$ than when at rest, there is a still further, but still more spurious, increase of resistance of the whole circuit as soon as it is employed to produce a current, *i.e.*, when subjected to a periodic impressed E.M.F. The total virtual resistance R^1 is, in fact, the hypothenuse of a right-angled triangle, of which one side is $\mathrm{R} + n\,\mathrm{L}$, and the other $2\,\pi\,n\,\mathrm{L}$ R, being the real wire resistance of the circuit, with the armature at rest.



If the resistance of an armature be measured from brush to brush at rest, it is found to be r, say. If it be measured in motion, spinning n times a second, using a constant battery current in the usual way, and taking care that no earth's or other lines are cut during the rotation, the equation to the current is

$$r\,\gamma + \gamma\frac{d\,\mathrm{L}}{d\,t} = \mathrm{E}; \quad \text{or} \quad \gamma = \frac{\mathrm{E}}{r + n\,\mathrm{L}}$$

so the resistance then measured is $r + n\,\mathrm{L}$. But the effective resistance when the armature is actually producing a current by rotation in a field of force is a little greater still, being, as just shown,

$$\frac{r + n\,\mathrm{L}}{\cos\phi};$$

or,

$$\sqrt{\{(r + n\,\mathrm{L})^2 + (2\,\pi\,n\,\mathrm{L})^2\}},$$

which, in case r is much greater than $n\,\mathrm{L}$, may be written

$$r + n\,\mathrm{L} + \frac{2\,(\pi\,n\,\mathrm{L})^2}{r + n\,\mathrm{L}}.$$

With this last expression Ayrton and Perry's numbers agree much better than they do with their own formula $r + n\,\mathrm{L}$; in fact, if L be taken as 4·2 the agreement is almost exact.

Digitized by Google

Results of Ayrton and Perry's Experiments on Resistance of Spinning Gramme Ring.

The resistance of the armature at rest was 1,768 ohms, and the increase at different speeds is shown in the following table, and compared with calculation :—

Revolutions. per second. n.	Observed resistance.	Observed increase of resistance.	Increase of resistance calculated from the formula $n\,L + \frac{2(\pi n L)^2}{r + n\,L}$	Calculated resistance.
0	1768	0	0	1768
10	1828	60	61	1829
20	1923	155	157	1925
30	2045	277	281	2049
33⅓	2103	335	338	2106

The agreement between observed and calculated resistances is almost exact; but probably this is only a coincidence. For the circumstances under which the resistance was measured by them (viz., with a steady battery current) ought to give the simple value $n\,L$ for the increase of resistance, and not the more complicated expression calculated above, which is the real effective resistance of an armature spinning in a magnetic field and producing a current.

One thing may be pointed out before closing, viz., that whereas the L in $n\,L$ means the self-induction of the armature, the L in $2\pi n L$ means the self-induction of the whole circuit; and this latter may be much greater than the other if the circuit contain electro-magnets or motors.

Separating the two L's, and denoting the one by L the other by l, the equation may be written thus :

$$L\frac{d\gamma}{dt} + (R + n l)\gamma = a\cos\theta,$$

or

$$\gamma = \frac{a\cos\phi}{R + n l}\cos(\theta - \phi),$$

where

$$\tan\phi = \frac{2\pi n L}{R + n l}.$$

The E.M.F. may be regarded as $E\cos\phi$, and the resistance as $R + n l$; or the E.M.F. may be regarded as having its simple value E, while the resistance of the circuit is

$$\sqrt{\{(R + n l)^2 + (2\pi n L)^2\}}.$$

The intermittencies of the current, and the effective resistance of the circuit, are therefore greatly increased when the external circuit has a high coefficient of self-induction, as, for instance, when the current is used to excite electromagnets; and a humming noise is accordingly heard from an electromagnet excited by a dynamo.

SUGAR REFINING BY ELECTRICITY.—Some further particulars as to this interesting process are to hand. On the occasion of the experiments recently mentioned by us, Prof. Friend, the inventor, ran through his machine several tons of a low grade West Indian sugar, producing in seven hours some forty barrels of refined sugar of the highest grade, every pound of which will prove to be nearly, if not quite, 100% pure. The particulars of the invention are, as follows:—The process is an electro-chemical one, which is worked by a machine, automatic in its action to a very great extent. As a paper-making machine is automatic, so is this in its working. Boiling and animal charcoal are entirely dispensed with. The process may, by comparison, be called dry. No syrups nor soft sugars of various grades are produced, the entire product being hard sugars, in whatever forms or sizes which may be desirable to produce, that is, from finest powdered up to and including cut and pressed loaf. One important feature in this manner of manufacturing must be observed—that all the saccharine matter in any parcel of raw sugar, is by this system rendered into hard sugar with a small loss, not exceeding 1% of the whole quantity.

ON THE "GROUPING SYSTEM" FOR THE DISTRIBUTION OF ELECTRICITY.

BY W. H. SNELL, A.S.T.E. AND E.

(Concluded from page 199.)

We have next to consider in what way the work of the batteries may be controlled from the engine room. It is evidently very desirable that the electrician in charge of the machines should be able at any time to ascertain the condition (so far at least as regards charge) of any one of the batteries. If this were done every morning he would be able to prepare a time table showing at what hour each battery should have completed its charge. The arrangement and apparatus described below might be tried for this purpose; but in the absence of experiments I do not of course express a positive opinion as to whether sufficiently accurate results could be obtained by the method proposed.

Each compensating room would be fitted with an instrument constructed and set up as follows :—An ampere-meter of some pattern which is read by the deflection of an index upon a horizontal scale has its index removed, and replaced by a counterpoised needle which projects beyond the scale. This needle carries a bridge of copper wire (or other suitable material) bent twice at right angles. The legs pass through the needle, and dip into two semi-circular troughs containing a saturated solution of $CuSo_4$, or other conducting solution. The troughs are concentric with the scale over which the needle moves. The inner trough is made of porcelain, the outer one of metal, preferably copper. This part of the apparatus is placed in circuit with a few Daniell cells. The current enters at the copper trough, and passes across the liquid to the copper wire which is carried by the needle; the resistance of this part of the circuit is thus practically the same, whatever may be the position of the needle. The current crosses the "bridge" and enters the solution in the porcelain trough. A copper electrode dips into the solution at each end of the trough, so that now there are two paths open to the current. The remaining connections are indicated in the diagram Fig. 2.

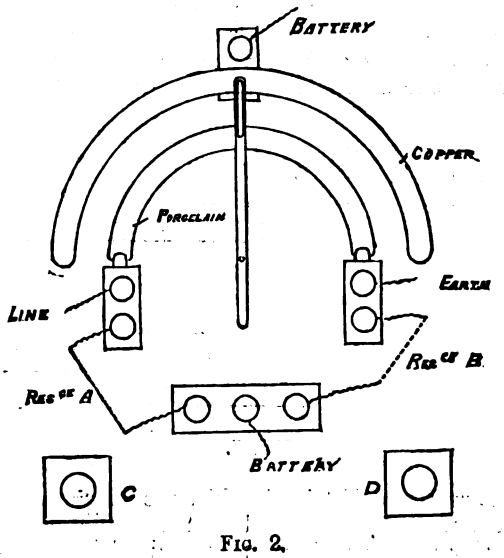


FIG. 2.

Resistance A = Resistance B (always). The Ammeter Terminals C and D are connected to the direct circuit of the secondary battery.

It will be seen that the solution in the porcelain trough occupies a position in the circuit of the Daniell's just similar to that of the wire in a "slide wire bridge," and that the wires corresponding to the galvanometer leads are taken to the machine room *viâ* "line" and "earth;" the "line" being an overhead wire; though probably it will be necessary to use a metallic circuit instead of an actual earth. At the machine room the current is taken into a voltameter provided with a graduated tube for collecting the liberated gas.

It will therefore be seen that if the ampere-meter be placed in the main circuit of the secondary battery the deflection of

Digitized by Google

the needle in either direction will determine a current from the primary battery through the voltameter; and the quantity of gas liberated will be a measure of the number of coulombs which has traversed the secondary battery. Further, when the current is reversed in the secondary battery it is reversed also in the voltameter circuit. When this happens a polarised switch (in the machine room) falls over, cuts out the first voltameter and inserts a second. Thus the condition of the accumulator as regards available charge is ascertained at once by a comparison of the two voltameters. Of course in this comparison we shall make use of a coefficient expressing the rates, $\frac{\text{coulombs of discharge}}{\text{coulombs of charge}}$, or we may graduate the collecting tubes in this proportion, or we may adopt other devices for making the reading direct. All that is required from this apparatus is to give each day some fairly approximate idea as to the number of coulombs which each battery requires to complete its discharge. The readings would, no doubt, require to be supplemented at intervals by more accurate observations. These might, however, be taken in each battery room, say once a week.

We will next consider in detail the process of charging the cells.

Some difficulty is here presented. It will usually be stipulated that the current shall be continuously available in the lamps. Now, during the process of charging it will be necessary to increase the potential at the machine terminals very considerably beyond the normal value ($N E_2$). It will be remembered that E_2 has always been taken as the E.M.F. of discharge. And as, especially towards the end of the process, the E.M.F. of the cells will be considerably higher than that of discharge, it will be obvious (see also equation 28) that when the batteries are charged in this way we cannot use the current in the lamp circuit during the process.

The following plan offers a solution, and although it adds to the first cost of the system, yet it brings with it several other substantial advantages which may be placed as a set off.

First, let the battery in each compensating room be duplicated; then we may make use of the two sets of cells either alternately or both in parallel. Further, the connections may be so arranged that during the daytime, while one set is being charged the other set may be discharging *over the same main*. The E.M.F. of the dynamo may now be anything we please without affecting the difference of potential at the terminals of the lamps. The diagram Fig. 3 will make this clear.

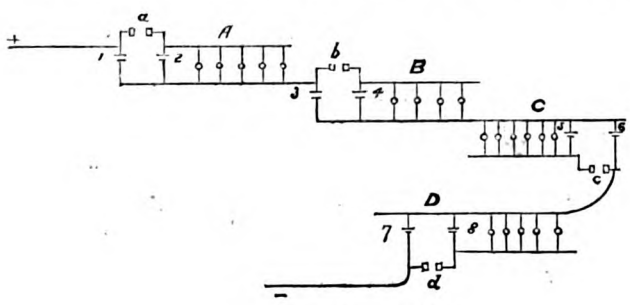

Fig. 3.

A and B represent districts in which the compensating rooms are situated at the positive end of the district, C and D are districts where they are the negative end. The switches, *a*, *b*, *c* and *d*, being open, batteries number 1, 3, 6 and 7 are being charged, and the lamps are being fed only by the remaining batteries. When the charging is completed the switches are closed, and one of each pair of batteries is disconnected. The lamps are then fed by dynamo and batteries together.

This solution does not quite hold good, however, for any compensating room which is not placed at one end of its district. In such cases it will be necessary to carry a separate charging main from this battery to the nearest battery in another district. This is shown in Fig. 4.

For charging we disconnect *a*—*b* and *b*—*d*, and join *b*—*c*. The lamps are not then in the dynamo circuit. For discharge (normal working) we reverse the above connections.

The additional advantages of this plan, which may be set-off against the extra outlay, are as follow:—

(1). The duplication of the cells affords a further security against breakdown.

(2). It helps to provide against any extra large demand for current.

(3). We may now more readily undertake to supply current for charging cells belonging to any customer by means of leads taken from any of the compensating rooms. This supposes that N has been taken small enough to allow the required margin for an increased E.M.F. of the machine.

(4). The batteries may be cut out of circuit one by one as soon as they are fully charged, and the E.M.F. and speed of the dynamo may be proportionately reduced, and as the number of ampere-hours required to complete the charge of batteries in the various districts may be expected to differ sometimes very widely, this should effect a substantial economy.

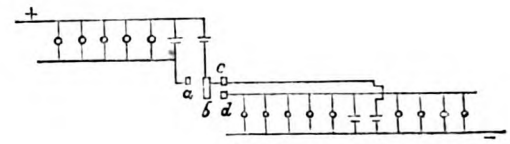

Fig. 4.

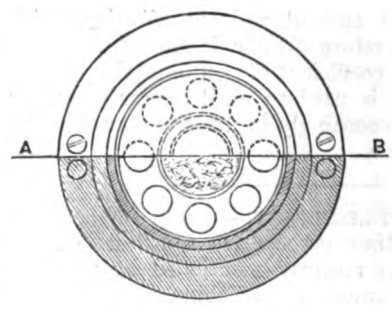
The voltameter observations will enable the electrician in charge of the machine room to determine each morning at what hour each battery will have completed its charge. By means of properly arranged switches placed on the same "line wire" as the voltameter circuit the required changes of connections may all be made from the machine room. It is not worth while to enter into detail at present upon this point, as the methods of arranging such devices are well understood. In practice it may turn out to be better to send a man to the spot at the proper time.

It is believed that all the essential points of the theory of the method have now been indicated. The system must evidently stand or fall mainly by the success or failure of the batteries.

THE BERTHON MICROPHONE.

The Compagnie Générale des Téléphones have for some time been employing a new microphonic transmitter, which possesses some interesting if not novel features. The variations of resistance in the circuit are produced in a packing of fragments

Fig. 1.



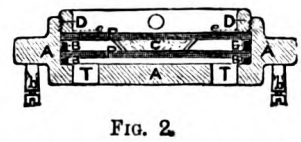


Fig. 2.

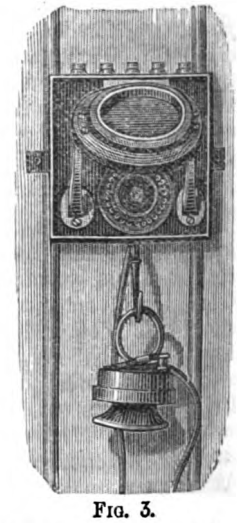

Fig. 3.

p p' are two circular carbon plates. B, an india rubber washer. C, the ring of ebonite containing fragments of carbon. A, circular ebonite box. O, opening corresponding to the diameter of the plate *p*. T T, openings pierced in the lower end of the box A. *b b'*, terminals to which the battery wires are attached (these latter are connected by platinum wires) to the carbon plates; and lastly B', a second washer separating the plate *p'* from box A, and allowing it to vibrate freely.

Digitized by Google

of carbon, a method which has the advantage of permitting of an infinite number of contacts. The apparatus, as will be seen by our illustrations, is composed of two plates of carbon, of 1 mm. thick and 60 mm. diameter, maintained at a given distance by an india-rubber washer, B. Between these two is the packing of carbon, contained in a ring of ebonite, C. Its action is as follows:—Each of the plates communicates with one pole of the battery in such a manner that when the circular ebonite box, A, is inclined the current or lesser resistance according to the inclination. Upon a traverses the fragments of carbon, which offer a greater sound being given into the mouth of the apparatus the two plates are put in vibration, and transmit their movement under excellent conditions to the fragments of carbon in the ring C. The box A is fixed at an angle convenient for transmission, generally 50°, and after being so placed requires no attention whatever. Fig. 3 represents a simple and inexpensive arrangement of the apparatus.

CORRESPONDENCE.

[We have been requested to permit those who are interested in the matters referred to in these and previous letters to meet at our office on Wednesday next, August 5, at 11 o'clock, in order to discuss the best method to be adopted in carrying out the desired object. We have much pleasure in acceding to that request, and will place a room at the disposal of those who wish to attend.]

INVENTORIES EXHIBITION GRIEVANCES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is quite time some steps were taken on behalf of the exhibitors, as suggested by Mr. Joel. May I be allowed to add the experience of the company whose exhibit I represent? As far back as March last, in reply to a circular we stated the amount of current required to show our lamps and apparatus in action, but at the opening of the Exhibition no current was forthcoming, and we were then informed that, in order to obtain a current, a special wire must be run, which, after some delay with the engineer, we obtained. We were daily promised that our wants should be attended to. However, this has not been the case, the wire has not been run, and no explanation could be obtained until a few weeks ago, when we were informed that a current of half the E.M.F. required for our Talenta lamps would be provided from one of the Exhibition circuits if we carried out certain requirements. As one of these consisted in our purchasing and conspicuously fixing an automatic cut-out from a firm with whom we maintain an honourable rivalry, and as the principal feature of our exhibit is Hedges' fusible and automatic safety device, we thought this was going a little too far, so our stall remains unlighted. In conclusion, may I refer your readers to the remarks in the *Engineer* of last week as to the necessity of an organised system of trials of exhibits, which in our case would have probably upset the *ipse dixit* complained of? With apologies for trespassing on your space.—Yours, &c.,

THE GLOBE ELECTRICAL AND ENGINEERING COMPANY,
per H. T. Tomlinson, Assistant Manager.

20, Dartmouth-street, Westminster, July 29, 1885.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read the letters which have appeared in your last two issues on the above subject with great interest, as, being an exhibitor, the matter fully concerns me; but I consider the bad treatment to which we have been subjected has been very poorly exposed. It is very evident that many of the *employés* consider their position to be such that it affords them an excellent opportunity for tampering with the exhibitors' time and patience. Facts speak louder than words. I mention the first instance in which some of the clerks asserted their powers in the above respect. This was in the ticket office. I know a firm that consists of three members, and, naturally enough, they each took an interest in getting their exhibit in order. The man to whom the task was given to allot the tickets gruffly told one of the firm that only one ticket would be given, and this (with the usual condition printed on it that it was not transferable) was to suffice for the three. After a certain number of shillings had been paid and a great deal of trouble given, a letter to the secretary obtained a grant of one more ticket. With the success that these exhibitions obtain one would scarcely credit the extreme niggardliness in refusing to allow a ticket to each of the principals. But this may be the fault of the subordinates more than that of the governing body, and I think this likely. However that may be, I have never heard such complaining from exhibitors as at this Exhibition, and the Executive Council may be assured that there is something wrong to cause such discontent.

Another instance of the over-officiousness of the men employed by the authorities is the following, which I believe to be a fact:—A certain firm, in trying to accede to the request of the ticket-changer, sent a couple of workboys down to change two passes on Saturday at the proper time. Shortly after the boys returned with the message that the tickets had been cancelled, because the boys had been suspected of trying to get a view of the Exhibition while changing the tickets. What an absurd excuse; it merely shows the paltry reasons deemed sufficient for exercising the powers of annoyance placed in these men's hands. The firm to whom I allude inform me that they sent one of their assistants down to inquire into the matter, and explain that the lads had been sent to change the tickets in accordance with request; but he was informed that the tickets were cancelled and they could not renew them. A letter, however, to the secretary a short time ago had the effect of renewing the tickets without a word of explanation, When I think of the above instances of refusal to supply *exhibitors* with tickets except after giving all the trouble possible, I cannot help thinking what a useless thing it is to ask for tickets for friends. It seems, so long as the Exhibition is a success financially, that that is all that is desired, and those who have spent their money in making it must be content with a reluctant permission for themselves to enter. It seems to me that when the list of gifts is published a full list of exhibitors should be attached, with a note to the effect that it is through *their* money and *their* brains the Exhibition has succeeded, and that they have been denied (in some cases) passes for themselves, and in *all* cases for their friends, in order to bring about this happy result.

I could cite many more cases in which the officialism complained of has been exercised to as great an extent as those already mentioned, but it will probably serve no useful purpose to state them now. In many cases the secretary has been appealed to, and I must add he has always acted as fairly as possible in every instance I have heard of. It is his subordinates who consider they have the right to tamper with those whose goods they are employed to protect.

Would it cost a great deal for the shareholders in this large co-operative business to be allowed the privilege of a free admission for a friend? The co-operative principle is splendid, and the success is gratifying; but the profits? Well, they are given away by the directors, and the shareholders have the pleasure of—seeing the money go.—Yours, &c.,

July 29th, 1885. ANOTHER EXHIBITOR.

P.S.—Our electrical friends might surely help one another to light their stands properly if the authorities will not light up their circuits in an efficient manner. Let them take the hint.

AN AUTOMATIC RESPONDER.—An ingenious device has been patented in America which will add to the usefulness of the telephone. The invention, briefly, consists, in adding a simple apparatus to each subscriber's instrument, so that any one calling up a distant station, &c., is automatically notified whether there is any person present to receive his call and message. The advantages of this addition to the telephonic system are sufficiently obvious.

THE INTERNATIONAL TELEGRAPH CONFERENCE.

When the propositions to be discussed by the Berlin Telegraph Conference have taken a more definite shape we shall have probably something very definite to say about at least one of them. But for the moment we will confine ourselves to the forecast of what is likely to happen disclosed at a friendly interview between the representatives of the English Cable Companies on the one hand, and the British merchants on the other, which took place in Broad-street on Wednesday last. It does not surprise us that the Chambers of Commerce were nervously anxious to learn how their interests are to be served at the Conference. Those interests are, it is well known, not exactly the interests of the Cable Companies; and every succeeding year adds fresh proofs that the basis on which the world's cable property was created is being gradually undermined, not merely by reckless competition, but by the economic selfishness of the commercial community.

No one could have imagined when these cable enterprises were set on foot that in a few years' time the system of codifying telegrams would have grown to the extent it has done, still less that it would go on increasing with every fresh reduction of the rates. But the companies have bravely borne up against their threefold enemies, competition, low rates, and codification, and have so far steadily resisted the temptation to propose any wholesale restriction on the use of Codes adverse to the interests of their customers. It was probably with feelings something like those of a guilty culprit that the Chambers of Commerce sought an interview with delegates of the companies prior to their departure for the Conference; and if public bodies are capable of the sentiment of gratitude, the London and Liverpool Chambers of Commerce ought to be grateful for another acquittal which apparently they did not expect, and which, in reality, nobody thinks they deserve. So far as the English Cable Companies are concerned no propositions opposed to the wishes of their Code-using clients will be made at the Conference.

In using the phrase economic selfishness as descriptive of the action of the merchants we do not mean it in any offensive sense. While the companies themselves, who are the only sufferers by a wholesale employment of Code telegrams, accept the situation philosophically, and on this point are evidently far more liberal in their policy than are the several Governmental administrations, it is not for us to cast reproaches on those who have simply availed themselves of the privileges which a word tariff inevitably affords and directly encourages. It would be impossible to prevent the employment of Code altogether, seeing that it finally rests with the sender to declare whether his message is in Code or not. But it cannot be denied that the system has been carried to an unlooked for and quite unwarranted extent—unwarranted, we mean, considering the lowness of the charges, which are by no means remunerative at present, and show very few signs of becoming so.

We think that the word tariff is primarily responsible for the coding system; and although perhaps the time has gone by for reconsidering that form of tariff, or for curtailing in any material degree the economic evasions to which it has given rise, still it is well to remember that there is a limit to the financial endurance of the great cable proprietors beyond which it will be impossible to presume without breaking down the cabling business irretrievably. This, of course, is out of the question; although such a result would be not altogether unwelcome to some at least of the merchants who are the cables' best customers. It is a significant fact—which the companies will probably not soon forget—that one of the commercial representatives at the interview on Wednesday stated that the merchants of England would subscribe a million pounds to sweep all the cables out of the seas. When language such as this is employed in the face of the men who have risked so much and gained so little by the enterprise for which the world at large will for ever hold them in the highest honour, we may be pardoned the use of the word selfishness as indicating the attitude with which they are confronted. The shareholders of cable property have experienced no mercy at the hands of those whom the Chambers of Commerce represent, and it is plain that none is to be expected.

This being so, it is desirable that the limits of codification should be more strictly defined, if not substantially curtailed. The barbarous and excruciating combinations into which the language is distorted for coding purposes is not merely vexatious to the operator, but a serious hindrance to the expeditious despatch of business. If senders could be brought to view the case in this light nothing further need be done in the way of regulation; but this is past hoping for, and the only amelioration at present practicable to which both parties

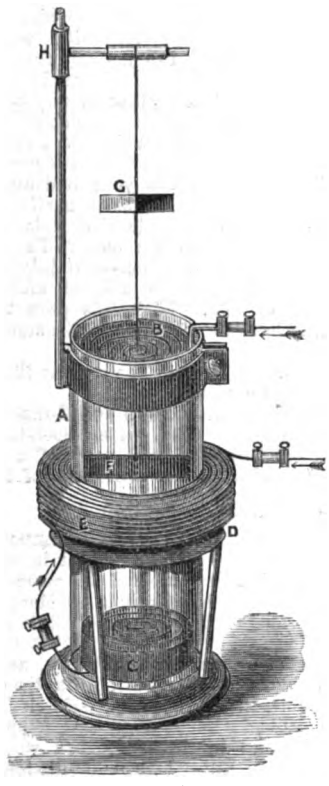
Digitized by Google

will assent is the adoption of a recognised vocabulary embracing every code word the companies are willing to accept. Difficult as the task of compilation would be, its completion would have the merit of finality, and finality in this relation is what the Cable Companies have a right to insist upon. They allege that the average length of the cablegram has been reduced by more than half under the Code system. And what makes matters still worse is, that the time occupied in signalling is, word for word, half as much again as it was formerly; and that consequently not only has the revenue been diminished, but the ability to deal with increased traffic, by which alone this loss of revenue can be made up, is lessened in a like proportion.

APPARATUS FOR SHOWING THE ELECTRO-MAGNETIC ROTATION OF ELECTROLYTES.*

BY DR. G. GORE, F.R.S.

This apparatus was devised and used for the purpose of investigating the influence of magnetism upon an electrolyte conveying a vertical electric current in the interior of a hollow and vertical electro-magnet.



Apparatus for Showing the Electro-Magnetic Rotation of Electrolytes.

A is a glass vessel 8in. high and 2in. diameter, nearly filled with an acidulated solution of cupric sulphate. B, a spiral ribbon of thin sheet copper ¼in. wide, wholly immersed in the liquid, and used as an anode by means of the connecting wire and binding screw attached to it. C, a similar spiral, used as a cathode, its connecting strip being passed through a hole in the side of the vessel and secured water-tight by means of sealing wax. D, an annular metal table with three legs, used to support a coil of wire. E, a coil of moderately stout insulated copper wire, about 2 or 3 inches in height. F, a perfectly flat vane of sheet copper, covered completely with varnish, and supported by a fine silk fibre. G, a vane of white cardboard, blackened on one half of each side, and attached to the fibre, in order to render manifest at a distance the rotation of the lower vane. H, a brass tube, supported by and sliding vertically upon a brass rod, I, and having upon its arm a closely-fitting tube of india rubber, used as a roller to which the silk fibre is attached, and by means of which the position of the lower vane is adjusted. For lecture purposes a much larger model of the apparatus is desirable.

With this apparatus and an electric current from two or three Grove cells passing through the liquid and the coil, rotation of certain portions of the liquid takes place. Opposite the central part of the coil, and at a point a short distance above the level of its upper end, and at another point at an equal distance below its lower end, no rotation of the liquid occurs. With a downward current in the liquid and a south pole at the upper end of the coil, as produced by the direction of current shown in the sketch, the liquid on a level with the top of the coil, and also that portion of it immediately below the lower neutral point, revolves in a dextro direction, whilst that on a level with the bottom end of the coil, and that portion immediately above the upper neutral point, moves in a laevo one. As a matter of course reversing the direction, either of the current in the coil or of that in the liquid, reverses the directions of rotation, whilst reversing the direction of current in both does not alter them.

Too strong a downward current in the liquid causes streams of light liquid, exhausted of metal, to rise from the lower electrode, and disturb the rotation of the vane, especially if the vane is not a perfectly flat one; and it is advisable to occasionally reverse the direction of the current in the solution. The apparatus is suitable for demonstrations of lectures.

* Read before the Birmingham Philosophical Society, June 11, 1885.

THE FORTHCOMING INTERNATIONAL TELEGRAPH CONFERENCE.

A Conference between the Representatives of the London and Liverpool Chambers of Commerce and the Delegates of the Submarine Cable Companies to the International Telegraph Conference, at Berlin, with reference to the propositions to be submitted to the Conference, took place at the office of the Eastern Telegraph Company on 29th inst. Mr. John Pender, M.P., Chairman of the Eastern Company, presided.

The CHAIRMAN stated that the Representatives of the different Cable Companies had been invited to meet Representatives of the Chambers of Commerce, who were desirous of offering some points for the consideration of the Delegates before the Conference took place. The companies were always desirous of giving their best attention to practical suggestions which would benefit their customers and themselves alike, but although the companies unitedly represented about £34,000,000 of capital and 100,000 miles of cables, against 7,000 miles of cable in the hands of the different Governments, they (the companies) had no vote at the Conference. The system was a most expensive one to maintain. They did not yet know what the life of a cable was, and the code system had pressed so hardly upon the companies that they could not possibly increase reserves or dividends. The object of the companies at the Conference was to prevent the existing arrangements between themselves and the public being interefered with; but they would at the same time ask that there should be an official dictionary or list of code words introduced which would settle the vexed question of what was and what was not a legitimate word. The directors of the companies were in the position of trustees, and had to earn a dividend for their shareholders as well as to maintain the system; but business had been cut so close by the merchants that the reduction could not continue or the companies would be obliged to ask for double tariffs for code messages. In his experience he had always found that the first consideration of the telegraph companies had been the public and how they could best serve them. In conclusion, Mr. Pender urged merchants when preparing codes to avoid those word combinations which took three times as long as ordinary words to transmit over the lines.

Mr. MURRAY, the secretary of the London Chamber of Commerce, read a letter from the Glasgow Chamber, setting forth the views of merchants there.

Mr. OGILVIE (Ogilvie, Gillanders and Co.) stated that the main thing Liverpool merchants wanted to know was, if there would be any further restrictions on code words which would involve a re-construction of existing codes and also a re-admission of proper and geographical names as one word whatever their length might be. The only other point he would refer to was as to the enclitic terminations "quo" "ve" "ne." It was a serious matter for merchants to have to pay double for such words.

Sir JAMES ANDERSON said if the codes were compiled according to the Convention rules, by which the companies were strictly bound, they would not have the trouble of altering their codes. The failure on the part of the companies to observe the rules might result in the forfeit of some of their concessions.

Mr. MACANDREW said previous changes made by International Convention had been in the direction of abridging the facilities enjoyed by the

Digitized by Google

public. It was rumoured that the limit of ten words was to be reduced to eight, but that had been denied by the Cable Companies. It was currently reported also that the use of inflections, plurals, &c., would be forbidden, and if this were so all the existing codes would be rendered useless.

Mr. NEIL (of Neil Brothers) referred to the inconvenience of the limitation of European code messages to one language. This, however, it was explained, the companies had nothing to do with. Mr. Neil, continuing, said a suggestion had been made at the London Chamber of Commerce that the companies should agree upon a list of not less than 200,000 words which they would allow the use of in all codes.

Sir JAMES ANDERSON said there were only two things which the representatives of the companies were agreed to propose at the Conference. First that the charges for rectifying telegrams should be under the control of the terminal administrations, so that the charge for repetition need not necessarily be collected until the message was proved to have been correctly transmitted in the first instance. The only other proposition was that *bonâ fide* names of stations or places, such as Rio de Janeiro in the address of telegrams should, even if in excess of ten letters, be counted as one word. As to codes, a great grievance of the companies was that some of the manufactured words occupied the line three times as long as ordinary language, and that the carrying capacity of any cable was mainly the number of words they could transmit in the six or eight busy hours of the day; the difficult manufactured words now coming into use reduced the capacity of cables. He thought that if the Berne Bureau should compile an authorised dictionary of the languages available for code purposes, with such inflections as might be admissible according to the usage of the languages, the companies would be very glad to adopt it and take their chance.

Mr. ANDREWS (Indo-European Company) called attention to the Convention definition of code language, and said that in addition to the delay in transmitting manufactured words the companies really transmitted free about one-third the average number of words of every commercial telegram, but he thought that if a representative body like the Chamber of Commerce were in favour of an official code, all difficulties as to illegitimate words would be done away with, and pointed out that groups of letters which did not fall within the Convention definition of a word should really be taxed as cyphers, of which three are counted to a word. It was due to the intercession of the submarine companies that eight languages were allowed for extra European code messages, as the Conference wished to allow only four. It was the companies also who had introduced the word rate.

Mr. WEAVER (Anglo-American Company) said the code system had been the ruin of the American traffic, and personally he would like to do away with it altogether. In 1872 the average number of words in messages was 18½; it was now 8½. None of the Atlantic Companies were making any profit, whereas but for the Codes they would be paying large dividends.

Sir JAMES ANDERSON said the Eastern Company did 54 per cent. more work, and earned only 12¼ more gross revenue. The Direct Spanish transmitted 102 per cent. more telegrams and lost money. In one Code which had come under his notice one word represented 109 words, and a Bank circular of 49 words could be expressed in two.

Another gentleman defended the use of unfamiliar combinations, because telegraph clerks "jumped" the terminations of well known words, and so frequently made mistakes.

Another speaker expressed the satisfaction with which he had heard what the propositions of the companies to the Conference were, and thought they were rather in the direction of increased facilities than otherwise.

Sir JAMES ANDERSON then briefly mentioned the propositions of the various Government Telegraph Administrations at the approaching Conference as far as they affected merchants using Code language.

The CHAIRMAN said the companies were endeavouring to obtain a continuous line of telegraph to the far East under their own control, and merchants might render much assistance by exerting their influence in favour of it, as it would facilitate telegrams passing to and from China, Australia, &c. In conclusion, he begged to thank the gentlemen present for attending the meeting, and he thought the conversation which had taken place would do a great deal of good.

The meeting then separated.

THE SUBMARINE CABLES BILL.

[The lack of space prevents us doing more than give a full report of the discussion in the House of Lords upon the Submarine Cables Bill. In a subsequent issue we hope to give the Bill as amended.—ED. *E.*]

In the House of Lords last week, before this Bill went into Committee,

The Marquis of TWEEDDALE said: My Lords—Before this Bill is considered in Committee, I trust your lordships will allow me to occupy your time for a few moments. My object in addressing your lordships is to record my protest against the manner in which the Convention which your lordships will presently be asked to pass into law was obtained. The title of this Convention is a Convention for the Protection of Submarine Telegraph Cables. I think that it is right that I should tell your lordships the nature of the property affected by this Convention. That property consists of 110,000 miles of submarine telegraph cables, of which 98,000 miles belong to private individuals or to public companies. The whole of the 110,000 miles has been laid at different times by English hands, is maintained by English hands, and the greater part is repaired from time to time by English hands. The value of the property, as far as it belongs to private individuals and companies, is estimated at thirty-four millions sterling, and the owners of this property are for the greater part inhabitants of the United Kingdom. That, my lords, is the nature of the property to which this Convention applies, and for the protection of which this Convention was held in March, 1884. The Convention was composed in this way:—Representatives of twenty-six Powers, namely, the Powers of Europe, two Asiatic Powers (the Shah of Persia and the Indian Government), the United States, and some eight or ten smaller Governments in North and South America, Costa Rica, and others of that description. The only feature which was common to the representatives of these powers was complete ignorance of everything connected with submarine telegraphs. I do not believe that there was one person sitting on the Convention who had any knowledge, either theoretical or practical, of the laying or maintaining, or repairing of submarine telegraph cables. That being the case, your lordships would naturally expect that the Convention would have communicated in some way with the owners of the valuable property to which I have referred. But they did nothing of the kind. They proceeded to legislate for them in complete ignorance, and they neither invited nor consulted the only persons who were capable of giving an opinion of any value upon the subject. The result is exactly what might have been expected—namely, a Convention which contains some articles of value, but includes others so objectionable that the owners of this large property, almost to a man, have petitioned your lordships that this Bill, designed for their protection, shall not become law. A petition was presented by the noble and learned lord (Lord Bramwell) who is sitting near me, representing something like four millions of this property. I had the honour of presenting one to-day which represented about 23 millions of money—27 millions out of 34 millions. Both those petitions ask your lordships not to pass the Bill, notwithstanding the fact that it was designed for their protection. What they say in one word is this—that so far from its being calculated to protect them, it is eminently calculated to injure them, and in some instances to ruin them. Now, I think the best evidence I can give your lordships that this is not an exaggerated view of the Bill and its probable effects is furnished by the amendments which the noble duke, who has charge of the Bill, has placed upon the paper. They deal with two of the most objectionable clauses in the Bill. I do not say that they deal with them adequately, but they do deal with them in an important manner. One amendment is very useful, and the other is very practical. I have also proposed amendments on these clauses, which in my humble judgment are in some respects superior to those which the noble duke has placed on the paper. I believe that the owners of telegraph cables prefer my amendments, and I hope to persuade your lordships, when the proper time comes, to take the same view. I have merely risen to record this protest, for I think that it is intolerable that a large and valuable property should be dealt with, as was the case in Paris last March by the Convention, without any communication—certainly no official communication—with those who were to be affected, and for whose benefit the Convention was ostensibly held. With this protest I shall reserve the further remarks I may have to make until the amendments come before your lordships.

The House then went into Committee upon the Bill.

Clause 1 was put and agreed to.

On Clause 2, the Duke of RICHMOND and GORDON said: My Lords—The noble Marquis (Tweeddale) has got an amendment to Clause 2. In order to shorten the proceedings I will accept Clause 2 with the words added on line 9, "Subject to the provisions of this Act." I see no objection to this.

Clause 2 was put as amended and agreed to.

On Clause 3, the Duke of RICHMOND and GORDON said: My Lords—With reference to the amendments which stand in my name in Clause 3, page 3, after sub-section 3, I have adopted this amendment in consequence of a representation which was made by the noble Marquis (Tweeddale) in an interview which I had with him and some other gentlemen who were interested in this subject. They pointed out that the clause in the Bill might affect the telegraph companies injuriously, and render them liable to be punished by a fine or imprisonment, if, in the exercise of their duty of mending their cable, they injure somebody else's cable; because, in mending their own cable, it might very well happen that they might damage another cable, and by so doing they would bring themselves within the purview of this Bill. I thought, therefore, that it would be right to consider the points raised by the noble marquis (Tweeddale), because I confess I felt there was some force in them, and therefore I have proposed an amendment which will run in the following words:—"A person shall not be deemed to have acted wilfully who, in order to the repair of one submarine cable, is unavoidably compelled, by reason of not being able to effect the repair otherwise, to break or injure another submarine cable; but this provision shall not apply so as to exempt such person from any liability to pay the cost of repairing such breakage or injury." And, therefore, when in the honest and necessary mending of his own cable, the owner of the cable damages another, he shall not be considered to have acted wilfully in that transaction; and it seems to me that those words will cover all that is desired, and protect the companies from what might otherwise, unless there had been an amendment, have been an injury to them. I am not quite sure that they would have fallen under the clause, but still I thought it better to explain it by those words, which certainly enable a person to repair his own cable without the risk of being sent to gaol for any mistake he might make in repairing his own. I beg to move that those words be inserted.

The Marquis of TWEEDDALE: My lords, I am anxious to state the objections I have to this amendment, the principle of which I agree with. The objects of the noble duke's amendment, and of mine, are to prevent the punishment of an entirely innocent man. In the Act, as it stands now, the captain of a ship may injure another cable, and thus render himself liable to punishment—fine or imprisonment. What I object to in this amendment is the ambiguous word "unavoidably." It would be almost

Digitized by Google

impossible to invent a word more unsuited to the kind of operations which take place in mid-ocean for the repair of a cable than the word "unavoidably." What is wanted is not that a particular act done by a captain in the way of repairing a cable where there are several cables lying, perhaps three miles deep, at the bottom of the sea is unavoidable or not. What we want to know is whether the ship is properly found; whether everything has been done to ensure the complete success of any particular expedition; whether the proper captain—the best man to be found for the work—was employed; whether the scientific persons accompanying the expedition were well instructed. Questions like those are of the greatest importance, and are easily investigated, but it would be almost impossible to arrive at any opinion as to whether any particular act performed by a captain of a ship was avoidable or unavoidable. It is obvious that in some cases, such as where one cable is overlying another, it would be impossible to repair the one without injuring the other, and such an act would be unavoidable in the strictest sense of the word. But this is a very simple problem compared with many which have to be dealt with. For instance, take the case of two cables lying, say, 10 miles apart. Supposing one of them has to be taken up, say A, and that the captain of the ship going out, with a perfectly honest intention of repairing cable A, by an accident of a kind which has occurred repeatedly in the Atlantic, grappled and injured cable B, lying 10 miles away—you cannot say that this was unavoidable. It was unintentional, but certainly not unavoidable, inasmuch as if the grappling irons had been dropped at a distance of nine miles all injury to the cable would be avoided. Whether this is so or not I cannot conceive a term which would be more calculated to puzzle people more than this word "unavoidable." The amendment I have put on the paper is this:—"Where a person does any act with the object of repairing a submarine cable, and takes all reasonable precautions to avoid injury to any other submarine cable, such person shall not be deemed to have acted unlawfully and wilfully within the meaning of this section." What is required by this amendment is that on a repairing expedition dealing with cables every reasonable precaution to avoid doing any injury to another cable is to be taken. That appears to me to be based on a sound principle. I believe that it is entirely consistent with English law, as it stands at present—certainly as the law has been interpreted by the department over which the noble duke presides. The Board of Trade, in a letter which they addressed to the chairman of one of the cable companies, dated 1st of July, 1882, with reference to this very question, whether protection could be extended to telegraph cables, made this answer:—"The Board of Trade have been informed by several other telegraph companies that the utmost measure of protection which they desire is to be protected from wilful and wanton or careless injury. The wishes of those companies seem to be practically satisfied by the English law as it at present stands. It appears to have been determined, both at common law and in the Admiralty Court, that a vessel, whether English or foreign, is bound, in dealing with a telegraph cable, to exercise ordinary skill and care, and that if either within British limits or beyond them a vessel does injury to a telegraph cable, which by the exercise of ordinary skill and care she might have avoided doing, she is liable in damages to the owners of the cable." That is to say, if ordinary skill and care and all reasonable precautions are taken the captain would not be liable for damages; and the authorities are given in the next paragraph. Then it goes on with regard to the jurisdiction:—"It appears also that any malicious injury to a telegraph cable committed within British jurisdiction or committed elsewhere by a British subject or a British vessel can be punished criminally in this country under the Malicious Injuries Act, and under the Merchant Shipping Act, 1852, sec. 267." Therefore, the effect of this letter addressed to the cable companies in 1882 was practically that the law provided all that was necessary for their protection. Now, this was assumed by the companies, and made them much less alert when the Paris Convention was sitting, because they felt that the law perfectly equitably and reasonally provided for the cases which they had submitted to the Board of Trade. The amendment now proposed is based upon the law as interpreted by the Board of Trade. It simply says that a company or an individual, if he undertakes to lay or repair a cable must, if he wants to avoid either civil damages or a criminal prosecution, take all reasonable precautions in carrying out the business which he has undertaken. For these reasons I venture to think that my amendment is, with all due deference to the noble duke, superior to the one that he has proposed. It is one which is approved of by the telegraph cable companies, and I think it will approve itself to your lordships.

The following is a copy of the amendment proposed by the Marquis of Tweeddale:—"Where a person does any act with the object of repairing a submarine cable and takes all reasonable precautions to avoid injury to any other submarine cable, such person shall not be deemed to have acted unlawfully and wilfully within the meaning of this section."

Lord BRAMWELL: My lords, as I presented the petition which has been alluded to by the noble marquis, I have now to make some observations on behalf of those whom I represent with reference to this particular clause. They come here with no ungrateful feelings towards this Convention. They think it a very useful one, and they are also grateful for this Bill which is to give force to it; but they certainly do feel, as the noble marquis says, that it would have been better if some experienced person in these matters had been consulted by them, and I cannot help thinking that this is a very dangerous piece of legislation. Now, my lords, the clause as it originally stood was undoubtedly open to the strictures mentioned by the noble duke. It seems to me that the amendment is an improvement upon it, and with great submission I think that the amendment of the noble marquis is an improvement on the amendment of the noble duke's; but still I am not satisfied with that, and I shall propose a third amendment to your lordships. The objection I have to the amendment of the noble duke is that in the first place it says that it shall not be deemed wilful to do that which is wilful—that is to say, if you can avoid it, and do it, it will be wilful, and, therefore, it is objectionable to say that shall not be deemed wilful which is not wilful. There is another objection to that word "unavoidable." Just consider what questions will be raised. It will be said that it was avoidable, you need not have done it, and you might have done it without causing the injury. Supposing this goes before a jury or any other tribunal—you say this man shall suffer five years' penal servitude though it was done perfectly *bonâ fide* and he did his best, but that he was not skilful enough or he might have avoided breaking the cable. Those are the objections to the amendment of the noble duke. I think that the objection to the amendment of the noble marquis is this. He says: "Where "a person does any act for the purpose of repairing a submarine cable, "and takes all reasonable precautions to avoid injury to another sub-"marine cable, such person shall not be deemed to have acted criminally." There the same difficulty almost arises. You did take all reasonable precautions to avoid injury, and you acted perfectly honest and *bonâ fide*, that you may have done; but if you had understood your business better you would have done otherwise, and therefore you suffer five years' penal servitude. It is not the intention of the noble duke, and it is not the intention of the noble marquis, that it should be so. Now, let us consider what your lordships have in view. What you have in view is to punish persons who, by culpable negligence or wilfulness, damage a submarine cable. That is the object you have in view. Consistently with that it is the intention, I am sure, of the noble duke, from the language that he has used, that people may, in attempting to get at their cable and repair their own cable, injure the cable of another company without committing a crime. It is not intended that they should commit a crime or run the risk of committing a crime if they, *bonâ fide* attempting to get their own cable, do some mischief to some other cable. That is the general intention, and I therefore respectfully submit to your lordships, and I thank the noble duke for the concessions he has granted and his good intentions towards the Cable Companies, and I think that this would be properly provided for by stating: "This section shall not extend to any case where, in the *bonâ fide* attempt to repair a submarine cable, injury has been caused to another cable, or the same has been broken; but this shall not apply so as to prevent their being liable civilly." Now, that seems a preferable amendment—if the noble duke will allow me to say so—to his, and a preferable amendment to that of the noble marquis, and I suggest it to your lordships. I am sorry to say that I did not give notice of it, as it was only recently that it was brought to my attention.

The Duke of RICHMOND and GORDON (to Lord Bramwell): Read it again.

Lord BRAMWELL: "This section shall not extend to any case where, in the *bonâ fide* attempt to repair a submarine cable, injury has been caused to another cable, or the same has been broken; but this shall not apply so as to prevent civil liability."

The Duke of RICHMOND and GORDON: My lords, I am under a very great disadvantage, because the noble and learned lord has brought forward an amendment of which I had not the smallest idea until the present moment.

Lord BRAMWELL: I am sorry to say that is so.

The Duke of RICHMOND and GORDON: And therefore I have not been able to give it all that attention which I ought. With regard to some of the remarks which the noble marquis made as to preferring his new amendment to mine, I must say that he is a very recent convert to the words which he has proposed in the amendment now under discussion, and proposed by him, because I am sure he will admit I am stating that which is a fact when I say that the amendment which I have proposed is his amendment, but amended by the insertion of one or two words; and therefore I was rather astonished to hear the noble marquis expatiate on the merits of his own amendment and on the demerits of mine, when, practically, I really adopted his amendment, and put in one or two words of my own. The noble marquis also referred to the difficulties of repairing cables in the Atlantic, but I think that the noble marquis will forgive me for saying that the amendment which I propose to insert in the Bill defines this to be within the 100-fathom limit, and therefore all that the noble marquis told us of the operation of this Bill in the Atlantic, he will forgive me for saying so, was not very much to the purpose, because my amendment confines it to within the 100-fathom limit. We all have the same object, I believe, and that is mending the clause so as to satisfy the parties that they will suffer no injury in the execution of what is their legitimate duty—that is to say, mending their cables. There are now three propositions before the Committee. There is the one which I proposed, and there is a second which is proposed by the noble marquis, and the third which is just now proposed by the noble and learned lord. I think that we have the same object in view. We seek by different roads to arrive at that object, but we all want the same common end. I do put my view of the case that my clause is better than that of the noble marquis. I will not put my legal experience in competition with that of the noble and learned lord opposite (Bramwell). His words may be better than mine, and I think that they are far better than those of the noble marquis, and therefore I take the liberty of suggesting to the noble and learned lord that if he would be good enough to print them, and bring them up on report, which I hope your lordships will be inclined to do to-morrow, I shall be able to see the words; and I can assure him that, if possible, I shall be prepared to accept those words unless they have a contrary effect to that which I believe at the present moment they have.

The LORD CHANCELLOR: My lords, I beg to call the attention of the noble and learned lord that we ought to see his words in print so that we may consider them on the report; but I must say that no form of language will get rid of a difficulty. In fact if a person is convicted of crime because he does something either negligently or wilfully, and if the question of negligence or wilfulness is to be determined upon the verdict of a jury, no form of words we can adopt in this House can avoid being remitted to the proper tribunal for discussion. I think that the word

Digitized by Google

"unavoidable," and the words "*bonâ fide*," and the words "reasonable "care," are all of them open to the same ambiguity that a jury will have ultimately to determine, and it appears to me that some course should be adopted by which ambiguity could be avoided as to what is an act of will, and in that sense wilful, as in the case put by the noble marquis, where a person intends to cut a cable in two because he cannot otherwise get at the cable which he means to mend. But that is not intended to be an unlawful act, and it is not negligent because he intends to do it. It is, in a sense, of his will, and in that sense wilful, and the problem is to show that which ought to be criminal is criminal, and that which is only negligent should be only negligent, at the same time time reserving the civil liability. I thought that the amendment of the noble and learned lord met that better than the other two, and I think that the only question is as to whether the clause of the noble and learned lord will be able to give the intention more accurately, and endeavour to avoid the difficulties I have pointed out, and I should advise my noble friend to accept the amendment.

The Marquis of TWEEDDALE: My lords, I merely rise to say that I do not quite understand the force of the noble duke's criticism in what he said that some of my remarks were not to the point, because his (the noble duke's) amendment confined the operation of the clause to within the 100-fathom limit. The amendment has nothing to do with the 100-fathom limit, which applies solely to Article 4 of the Convention dealing with civil remedy for damage.

The clause was then agreed to *pro formâ* to admit of Lord Bramwell's amendment being considered on report. A new Clause 3 was proposed by the Marquis of Tweeddale, viz. :—"Article IV. of the Convention shall apply only to cables laid after this Act shall have come into force; but nothing in the Convention or this Act shall take away, prejudice, or affect any right or remedy to which by law any party is or may be entitled otherwise than under the provisions of the Convention or this Act."

The Duke of RICHMOND and GORDON said: My lords, I propose to accept part of this. This amendment, or rather this new clause, is proposed to be inserted after Clause 3, and is intended to meet the objections which have been raised by various parties interested in those cables, and where they complain that the scope of this measure goes far beyond that which was reasonable that it should do; and it would be very difficult indeed in mid-ocean to take up the cables, especially in some parts of the ocean where they cross over and where they are placed in close proximity to one another; and it would be almost impossible to deal with them in a manner which would be satisfactory. After consideration of the subject, and after consulting with some of those who I thought could give me good advice upon the subject; and after hearing what the noble marquis and his friends said on the occasion when they came to the Board of Trade, it occurred to me that it would be better that Article 4 under the schedule of this Act should only apply do a depth of water not exceeding 100 fathoms, because I am told that within the 100-fathom limit—which is so well defined in all the charts that there is no difficulty in finding it, and there is no difficulty in dealing with the cables within that depth of water—that it is, comparatively speaking, very easy to pick up and repair cables within the 100-fathom limit; and therefore I propose to meet the objection which the noble marquis made by proposing this "Article 4 of the schedule in this Act shall not apply to that part of the cable which is laid in a depth of water exceeding 100 fathoms." And then I propose to take the last part of the noble marquis's amendment in the same article, and insert these words:—"But nothing in the Convention or this Act shall take away, prejudice, or affect any right or remedy to which by law any party is or may be entitled otherwise than under the provisions of the Convention or this Act." I believe and I hope that it will meet the objections of the noble marquis, and I shall ask your lordships to insert this clause in the Bill.

The following is a copy of the amendment as agreed to (to be Clause 4 of the amended Bill):—

4. Article 4 of the schedule to this Act shall not apply to that part of a cable which is laid in a depth of water exceeding one hundred fathoms, but nothing in the Convention or this Act shall take away, prejudice, or affect any right or remedy to which by law any party is or may be entitled otherwise than under the provisions of the Convention or this Act.

The Marquis of TWEEDDALE: My Lords, I am very much obliged to the noble duke for the manner in which he has endeavoured to meet the wishes of those who object to this clause in the Convention. I have only to say that I accept the amendment.

The Earl of CAMPERDOWN: My Lords, may I ask the noble duke whether it is possible with reference to the terms of the Convention itself to make these alterations? The first article says:—"The present Convention applies outside territorial waters to all legally established submarine cables landed on the territories, colonies, or possessions of one or more of the High Contracting Parties." Now you are going to limit the Bill, which has to become an Act of Parliament—you are going to limit the application of this Act of Parliament to a certain set of cables. The Convention is to apply to all cables.

The Duke of RICHMOND and GORDON: The answer to that is that you cannot make Parliament do other than that which it chooses, and all that this country has done is to recommend the Convention and the contents of this Bill to the Legislature, and the Legislature is at liberty to deal with that Bill as it thinks fit. If it is not in the mind of Parliament to carry the whole of the Convention, we cannot insist upon this being done.

The Earl of CAMPERDOWN: "The high contracting parties" necessarily implies that we are parties to this Convention, and that we are to bring in measures for carrying the Convention into effect. Article 3 says:—"The High Contracting Parties undertake that, on granting a concession for landing a submarine cable, they will insist, so far as possible, upon proper measures of safety being taken, both as regards the track of the cable and its dimensions"—that is to say any submarine cable. My reason for asking this question is this, that I am very much afraid that we are going to establish a very excellent and thorough method for the punishment of British subjects. But what is passing through my mind is that the most dangerous time for a nation is when it is at war, and the case when a nation is at war is especially barred by this Convention. But this is a very dangerous moment, for it is just the time when operations dealt with by this Bill are likely to be undertaken by Submarine Cable Companies. And suppose there are other foreign nations who have not passed through their Legislatures measures which will punish adequately their subjects engaged in these operations, the result will be that English subjects will be punished thoroughly, because of course this law will be applied, and fairly and justly, in the English tribunals. And how do we know that foreign subjects who are engaged in that way will be punished at all? This is a limitation of the Convention.

Clause 3A, as amended, was put, and agreed to. Clauses 4, 5, 6, 7 and 8 were severally put and agreed to.

The Earl of REDESDALE: You wish to insert a new clause after Clause 8?

The Marquis of TWEEDDALE: Yes.

The Earl of REDESDALE: Leaving Clause 8 in?

The Marquis of TWEEDDALE: Yes. This clause which I have to submit to your lordships' approval is connected with Article 3 of the Convention, a very important article. My amendment is proposed in order that this article shall have effect given to it. The article is this:—"The High Contracting Parties undertake that, on granting a concession for landing a submarine cable, they will insist, so far as possible, upon proper measures of safety being taken, both as regards the track of the cable and its dimensions." Now, the object of this amendment is to secure in the future that a cable shall be laid in such a way that it shall not cause any injury to any other cable or lead to any injury. This is a very desirable thing. If this precaution had been taken earlier none of the difficulties, or scarcely any of the difficulties, which have arisen in connection with submarine cables would have taken place. Now, my lords, what I propose is that before any future concession becomes valid, it shall be treated as a provisional order. That is the principle of the amendment. In other words, that this concession shall be laid on the table of your lordships' House for a certain number of days, so that it may be examined and discussed, and, if necessary, objected to. Now, my lords, at present there is no machinery whatever for ascertaining the nature of a concession. A concession may be granted by the Board of Trade or by the Post Office, and nobody can see or know the terms of that concession. I do think that a concession should not be given to any person which has not been published to the world, and subjected to such criticism and inquiries as should enable any person who has any objection to it to lodge his objection. It is not necessary to read the amendment to your lordships. The question I submit is a question of principle, whether it is or not desirable to have concessions before they are granted laid upon the table of your lordships' House in order that they may be examined and objection taken to them and investigated if necessary. I beg to move that amendment to your lordships.

The amendment is as follows:—

"With respect to concessions to be hereafter granted of the right of landing submarine cables on the shores of the United Kingdom, the following enactments shall have effect:—1. No such concession shall be granted unless public notice of the application for and purport of the proposed concession has been previously given by advertisement once in the *London Gazette*, and twice in two successive weeks in two daily morning newspapers published in London. 2. Before any such concession be granted, the Board of Trade shall consider any objections which may be made thereto by any company or persons affected thereby, and of which notice in writing shall be given to the Board of Trade within 21 days after the date of the insertion in the *London Gazette* of the advertisement mentioned in this section. 3. A copy or statement of the material provisions of every such concession shall be inserted in the *London Gazette* within 14 days from the date thereof, and copies shall be laid before both Houses of Parliament within the like period if Parliament be then sitting, and if not, then within 14 days from the next sitting thereof."

The Duke of RICHMOND and GORDON: My lords—I have the strongest objection to this clause proposed by the noble marquis. In the first place the noble marquis talks about the concession, that it should be placed on the table of this House as a provisional order before it is granted.

The Marquis of TWEEDDALE: Before it is valid.

The Duke of RICHMOND and GORDON: It seems to me that the object of this clause proposed by the noble marquis is very much in favour of the existing companies, because if this clause proposed by the noble marquis was to take effect it would be very difficult for a new company to be established, because means might be taken during the time that they were making the application for the old companies to come and endeavour to buy up that which was proposed to be started. But I think that the noble marquis must have forgotten that the concessions which are granted by the Board of Trade are only concessions on the foreshore that is under their jurisdiction. There are other parties who have the right of making concessions. There are the Commissioners of Woods and Forests; there is the Duchy of Cornwall, where several cables are laid; there is the Duchy of Lancaster, and there are corporations who have the right, and also the Crown. And it would be a great hardship to any one to whom the foreshore belongs that he should not be able to grant a concession to a cable company to land on his own property without coming to Parliament and having it treated as a provisional order. Now, the noble marquis said that he proposed this clause also on the ground of safety, and that cables should not be laid in an improper manner. My lords, I believe it is the practice at the present time at the Post Office to give notice when they are laying down cables such as the noble marquis has alluded to—to give notice to cable companies in the vicinity of which the new cable is proposed to go, in order that they may be informed as to what is about to be done. And therefore I say that in the existing practice of the Post Office there is

Digitized by Google

sufficient to carry out what the noble marquis proposes. And in the next place, I say that it is a very hard thing to compel persons who have the right to grant concessions to come to Parliament to ask Parliament to do that which they are enabled to do themselves; and therefore it is that I must offer my opposition to the proposal of the noble marquis.

Lord BRAMWELL: My lords, I beg to say a word in support of the noble marquis's proposition. There is difficulty in doing it I do not deny, but I should doubt very much whether any one would lay down a cable merely because he has got the permission of the owner of the foreshore. There will be some question as to the three mile limit. I do not want to trouble your lordships with the discussion of the matter where thirteen judges differed, in 1876, on this question; but I should doubt whether any one would be safe in laying down a cable merely because he got permission of the owner of the foreshore. I may say that I almost suggested this amendment to the noble marquis. The difficulty is this—here is an existing cable, another being proposed to start from a point near it, and either wilfully or not knowing where the first cable lies, perhaps it crosses it at a short distance from the shore, when they might just as well have started from some other point, and it would be a desirable thing that they should do so. Now, if some tribunal could decide as to the reasonableness of the starting point chosen, it would be an advantage. That was my object in making the suggestion.

The Marquis of TWEEDDALE: My lords, I beg to say that this is the only amendment which is not in any way inspired by the telegraph cable companies. I have had no communication from any of them on the subject, and there is no intention on my part of stopping other parties from getting concessions. One other observation I have to make. What I referred to was a concession made by the Government—not to a concession by private individuals. Article IV. of the Convention says:—"The High Contracting Parties undertake on granting a concession"—by the word "concession" I meant a Government concession; and I shall be happy to introduce words making this clear should the noble duke be willing to approve the principle of the amendment. With regard to the statement which the noble duke has made referring to the manner in which the Post Office gives notice, in cases of new concessions, and the expression of his opinion that such notice is sufficient, I beg to point out to the noble duke that the telegraph cables which have crossed other cables in the Atlantic more than any other of recent times were the cables last laid, and regarding which that very notice was given. The security afforded by the notice referred to by the noble duke is therefore, or at any rate has proved hitherto, altogether illusory. If this amendment is not adopted Article 3 of the Convention will remain for ever a dead letter. The amendment is proposed entirely in the interests of the public, for I believe that the public have a great interest in submarine telegraph concessions—that they should contain no conditions but such as are for the general benefit of the community. It is in the public interest that I ask your lordships to declare that in future the conditions of concessions shall be made known before they beome valid, and I shall ask your lordships' opinion upon the amendment. Clause 8A was then put and rejected without a division. On Clause 9—

Lord BRAMWELL said: My Lords, I wish to make a suggestion to the noble duke. By Article 4 of the Convention the owner of a cable who breaks or injures another cable will "bear the cost of repairing the breakage or injury, without projudice to the application, if need be, of Article 2 of the present Convention." Now, it appears that those who are interested in this matter think that this is really a very unjust provision; in this way—there are, I believe, two cables now which go to America, which can be used, but which are really worn out, and there are other cables that are not repairable. The only thing that can be done if they were broken would be to substitute a new one, and this article almost imposes an impossibility on those who may be so unfortunate as to break such a cable as that. They cannot grapple it up and repair it, but they can substitute another. That would not be repairing; but in the next place it would be substituting new for old without a reasonable allowance being made. If the noble duke thinks it worthy of his attention I shall be glad to amend that.

The Duke of RICHMOND and GORDON was understood to say that he would take it into consideration.

The Bill as amended was then passed through Committee of the whole House, and ordered to be reported.

On Friday, July 24, the subject was resumed.

The Duke of RICHMOND and GORDON: My Lords, I have had an amendment submitted to me by Lord Bramwell, and it has just been laid on the table of the House, and with the consent of the noble lord I will read it. On Clause 2, page 3, after Sub-section 3, to insert as a new subsection, strike out in the printed copy of the amendment the words "provided that," and let it run, "A person shall not be deemed to have unlawfully and wilfully broken or injured any submarine cable where, in the *bonâ fide* attempt to repair another submarine cable, injury has been done to such first-mentioned cable, or the same has been broken; but this shall not apply so as to exempt such person from any liability under this Act or otherwise to pay the cost of repairing such breakage or injury."

The amendment was then formally put and agreed to.

The Earl of CAMPERDOWN: My Lords, on the motion for receiving the report I wish to ask a question on a point which requires explanation. I tried to do so yesterday, but on that occasion I was not so fortunate as to obtain an answer. I must remind your lordships that this Bill is brought in for the purpose of putting in force and for making regulations on behalf of the English Government to carry out the terms of the Convention. The Convention itself does not come under discussion, and I do not quite understand how the Committee yesterday were justified in inserting a new clause which appears to be a limitation of Article No. 4. The Government of the Queen undertook to take the whole of the necessary measures in order to carry out the terms of that Convention; but this clause proposes to limit one portion of it, and I do not see how it is consistent with the duty of the Government that that is done.

The Duke of RICHMOND and GORDON: My Lords, the Government has to submit a Bill embodying the recommendations of the Convention to Parliament, and that of course must be dealt with according to the wishes of Parliament. The Government cannot undertake to carry through the Convention entirely, they can only get that part of it which Parliament will sanction.

The Earl of CAMPERDOWN: The noble duke and his colleagues have not gone so far as they might to carry out the Convention. Parliament has refused nothing; but the noble duke has imposed a limitation and not Parliament.

The Earl of SELBORNE made some inaudible remarks.

The Marquis of SALISBURY, who was very indistinctly heard, was understood to say that the Government took the course which appeared to them reasonable, and gave Parliament the opportunity of confirming the Convention, and the Bill covered those parts of the Convention which were essential.

The Earl of CAMPERDOWN: My Lords—The noble marquis seems to forget that the other Governments may make different arrangements, and the result may be that may say "You are not carrying out the terms of the Convention, and then we on our part will not do so."

The Bill was ordered to be reported to the House as amended.

It was read a third time and passed, with the amendments, on the 27th inst., and sent to the House of Commons for approval of the amendments.

LEGAL.

In Re Edwards's Trade Mark.

In the High Court of Justice, Chancery Division (before Vice-Chancellor Bacon), on Wednesday a summons by Messrs. Felten, Guilleaume and Co., asking that the Register of Trade Marks might be rectified limiting the trade mark No. 14,288, the property of Mr. T. E. Edwards, to unwrought and partly-wrought metals, used in manufacture, other than steel and iron wire, came on for hearing. In 1883 Mr. Edwards took an assignment of trade mark 14,288 from Messrs. Cromar, Scott, and Co., of Liverpool, who, in 1878, registered their "Neptune Iron" and "Neptune Brand," in respect of all goods in Class 5. On the 20th of March, 1880, Messrs. Felten, Guilleaume and Co., of Mulheim, near Cologne, registered trade mark No. 22,141, in respect of "steel wire and iron wire," in Class 5. Edwards's trade marks had a figure of the god Neptune with a dolphin's tail in the sea and carrying a trident. Felten's trade mark was the head of a trident with the letters "F.G." on each side and the word "Neptune" underneath. In 1884 Mr. Justice A. L. Smith granted an injunction restraining Mr. W. F. Dennis, the London agent of Messrs. Felten, Guilleaume and Co., from using their Neptune trade-mark on steel or iron wire. In April last an application was heard before the Vice-Chancellor on behalf of Mr. Edwards, asking that Messrs. Felten, Guilleaume and Co.'s trade mark might be struck off the register, and his lordship reserved judgment pending an appeal from the judgment of Mr. Justice A. L. Smith.

Mr. ASTON, Q.C., and Mr. JOHN CUTLER, for Messrs. Felten, Guilleaume and Co., contended that though Mr. Edwards's mark had been registered for five years it never had been registered in respect of the particular class of goods manufactured by the applicants—namely, steel and iron wire.

Mr. HEMMING, Q.C., and Mr. P. OGDEN LAWRENCE, for Mr. Edwards, urged that his trade mark having been on the register for five years was conclusive; but, as a matter of fact, the registration, apart from Section 3 of the Trade Marks Acts, 1875, was good.

The VICE-CHANCELLOR said that Messrs. Cromar, Scott and Co. never did manufacture steel and iron wire, and, therefore, never assigned any goodwill of that manufacture to Mr. Edwards. Mr. Edwards, therefore, had no right to prevent Messrs. Felten, Guilleaume and Co. from using their trade mark to these goods. But then it was argued that the Court had no jurisdiction to alter the register after the expiration of five years. His lordship had no doubt of the right of the Court to rectify the register after five years in proper cases, and made the order in the terms of the summons, reserving the question of costs.

COMPANIES' MEETINGS & REPORTS.

The Direct United States Cable Company (Limited).

The sixteenth ordinary general meeting of this Company was held at the Cannon-street Hotel, London, E.C., on Friday, the 24th inst., under the presidency of Mr. John Pender, M.P.

The SECRETARY and TRAFFIC MANAGER (Mr. J. W. Fuller) having read the notice convening the meeting, the Directors' report and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, the revenue for the half year to 30th June, after deducting out payments, amounted to £36,106. 1s. 1d., and the working expenses, income-tax, and other payments (exclusive of cost of repairs) absorb £17,206. 15s. 11d., leaving a balance of £18,899. 5s. 2d. as the net profit of the half year, making with £17,251. 2s. 11d. brought from the previous half year, a total of £36,150. 8s. 1d., which has been appropriated as follows:—Interim dividend of 3s. per share to 31st March, £9,106. 10s.; proposed final dividend of 3s. per share to 30th June, £9,106. 10s.; transferred to reserve fund,

Digitized by Google

£7,203. 13s. 6d. ; balance carried forward £10,733. 14s. 7d.—total, £36,150. 8s. 1d. The revenue shows a decrease of £32,467 as compared with the corresponding period of last year, owing to the operation of the reduced tariff, to competition, and to the continuation of that general commercial depression from which our business has suffered for a considerable time past. The expenses in London are slightly higher, while those at the stations are lower than in 1884. It will be observed from the details given in the accounts that this reduction in the stations' total expenditure has been effected in spite of a considerable and unavoidable increase in the item of printing and stationery. We have incurred special outlay on law account during the past half year, but the matters in question were finally settled prior to the 30th of June. With the exception of income-tax (increased by the 8d. rate), the remaining items of expenditure are practically unaltered. The reserve fund, after being charged with £2,858 for cost of repairs, now amounts to £310.000. The Company's investments amount to £304,921. 4s. 1d. The present market value of the securities is in excess of their cost to the Company. When I had the pleasure of addressing you at the last half-yearly meeting I made what I then believed would prove to be a correct statement as to the probable result of the competition upon which we were then entering. I stated that the reduction of the rate from 2s. to 1s. 8d. would involve a loss of at least £150,000 a year. That statement has been fully confirmed, and more than this, there has been no corresponding increase of traffic to recoup that loss ; the depressed state of trade in America has still further tended to reduce the gross traffic, so that during the six months the traffic and returns have steadily declined. I then also mentioned that the two new cables introduced by Messrs. Mackay and Bennett were entirely superfluous, and those cables have done nothing to create new traffic, but have simply taken away a portion of the current earnings, which have been lessened by their hasty and ill-advised reduction. During the last six months the companies working in concert with us have all had their cables interrupted more or less—in fact we have had to work at different periods with six, five, and four cables respectively, instead of with eight cables ; therefore the proportion going to the two new cables might appear to the proprietors of those cables more satisfactory than it really is, because had we been working with all our cables their receipts would have been proportionately less ; but even as it is their earnings have probably amounted to about 28 per cent. of the receipts. With such a return they cannot possibly be satisfied. One of the Western Union cables and that of the French Company are still broken ; but no doubt they will be very shortly repaired during the fine weather, so that a reduction of the Mackay-Bennett proportion must follow, and I think I may say without much hesitation that when all our cables are at work it is not likely their proportion will reach 16 per cent. Now, the figures which I have quoted justify me in making the remarks which I am now going to do, viz., that when I last addressed you I told you you must be prepared to look a reduced dividend in the face. That reduced dividend, I am sorry to say, has come about. We are, therefore, now in the position of either having a higher rate or being obliged for a time to make a considerably lower one, because to work at the present tariff, with no immediate prospect of any increase in the traffic, we consider, as men of business, would be unwise. I am, however, hopeful that when those interested in the Mackay-Bennett venture find that the business is such an unsatisfactory one we cannot conceive that they will not be anxious to come to some understanding which will increase their earnings. I have always stated that very low rates must bring about a reduction, and that if the public reap the benefit of them at one time they must pay for them at another, and considering the precarious nature of the property, and the large amount of money invested in it, and that Atlantic telegraphy has now become a public necessity, we think we are entitled to such rates as will give a fair return, and your Directors are prepared to take every step possible to bring about such a result. At the present moment there is a very serious—I might almost say a very disastrous—competition going on between the telegraph land lines in America. The Western Union, as you know, was the pioneer company, and the company which has opened up America in a marvellous way by its telegraph system. As I have before stated, there is no place in the whole of the United States of even secondary or tertiary importance where this system is not to be found ; and you will remember that at one of our meetings I mentioned the fact that even on the frontiers of the Indian Reservations I found the Western Union Company established. The Western Union Company has no doubt absorbed during the last few years a considerable number of minor companies which were established to compete with it. This business of building lines to be sold was for a time supposed to be a very profitable one to those who built them, but during the last two or three years the reverse has been the case, and several companies that have been established have gone into liquidation. Mr. Mackay has associated himself with one or two land line companies with a view to collect traffic for his submarine system. I believe that the whole of the land line system in America at the present moment is so unsatisfactory owing to competition that the probability is that before a permanent settlement of the submarine system can be made there must be some arrangement come to by those land line companies, and looking to the fact that those companies are now carrying traffic at rates which are likely to materially reduce their dividends, and in all probability to cause the younger companies to give no dividend at all, and considering that Americans are as a rule shrewd men of business, I hope that this will only go on for a short time. The land line question being settled, then the probability is that the submarine system will be placed on a more satisfactory basis than it is at the present moment. In addition to Mr. Mackay's system there is also the Baltimore and Ohio Company, which is a very powerful railway system, and with which is connected a very important telegraph system, and no doubt, in any arrangement that is made with the land line companies, this line will have to be considered. What astonishes me is that this competition has gone on so long with such unsatisfactory results to the companies concerned. I therefore hope that before the next meeting I shall be able to put before you a statement with brighter prospects than I am prepared to submit on the present occasion, and I may also state that we shall endeavour to do this at as small a cost as possible. We are most anxious to protect our shareholders' interests, and return to the old 5 per cent. dividend ; but if for a short time I am compelled to ask you to accept a still further reduced dividend, I shall ask you to do so in the belief that it is done for the purpose of placing your property in a sounder and more productive position in the future. I now beg to move—"That the report of the Directors, dated the 10th July, 1885, together with the statement of accounts to the 30th June, 1885, annexed thereto, be and the same are hereby received and adopted, and that a final dividend be now declared of 3s. per share, free of income-tax, making, with the interim dividends already paid, a total dividend of 4 per cent. for the year ending 30th June, 1885." With regard to the dividend to-day, we are paying you at the rate of 3 per cent., making 4 for the year. It must be borne in mind that during the first six months we were working under the two shilling tariff, and during the rest of the period at one and eightpence tariff.

Mr. W. FORD seconded the motion.

Mr. GUESPON took exception to the fees paid to the Directors, and pointed out that the Articles of Association empowered them to have five Directors and not more than eight. He suggested that in future balance-sheets the cost of each security should be given.

Mr. GRIFFITH, referring to the unpleasant state of things now existing between the various submarine companies, and the disastrous consequences it had had on the returns of the Direct Company, said the question that they had to ask themselves was, Could the evil be remedied ? He was sorry to hear the Chairman state that there was a prospect of the dividend being reduced during the next six months. There was no doubt that while warfare continued between them both companies must suffer. If peace were restored, no doubt the other company would still gain something ; but so would the Direct Company. The public at present received a benefit from telegraphy for which they gave no adequate return. The public were the persons who received all the benefit ; therefore he thought they ought, without injury to the public at large, to consider whether some amicable arrangement could not be made by which the value of their property might be increased, and the prospect of good dividends brought within their view. He hoped before they met again that the able gentlemen who sat at the Board would be able to effect some advantageous arrangement. With regard to items of outlay, he found that during the last half-year they had spent a large sum in law expenses.

Mr. WM. FORD : It is quite an exceptional charge, and is not likely to appear again.

Mr. GRIFFITH said he found from the report of the Anglo-American Company just issued that the Directors of that Company intended to reduce their contribution to the reserve fund by £50,000. He wished to ask whether the Directors of the Direct United States ought not to take a leaf out of their book ? Of course, it would not be wise to diminish that fund if there was any prospect of their not being able to carry on the business in safety without increasing that fund.

Mr. JOHN NEWTON wished to give expression to the opinion that the Company would have no peace until it was prepared to fight the competing schemes. He thought if the shareholders were content to go for a few years without a dividend they would have very excellent dividends for ever afterwards. It was perfectly absurd for the existing companies with the vast experience they had had to talk about "squaring" or making arrangements with their rivals. He sympathised with what Mr. Guesdon said as to the fees of the Directors, and he would support that gentleman if he (the speaker) found that in the future the Directors were not prepared to take vigorous action and fight the competing undertakings. They could not make any arrangement that would be satisfactory until they had completely beaten their opponents.

The CHAIRMAN : I shall reply to Mr. Guesdon first. Mr. Guesdon taxed the Directors upon more grounds than one. I am very much astonished at the way in which he asks us the question whether we take any interest in the question of the reserve fund, and how we have invested it. I should think if there is one duty of Directors more important than another it is to see that the money that passes into their hands is faithfully and honourably invested. That we profess to do, and take the responsibility of it, and I may say that at the present time we stand in reference to our investments in the best possible position. We sold some securities to pay off the £100,000 debentures at a considerable profit, and those that we hold to-day are in excess of the price they cost us. Therefore you cannot blame the Directors for want of judgment or foresight. I do not claim any greater foresight than my neighbours, nor do I claim it for my Board, but this I will say, that there is no question more thoroughly sifted, and no subject as to which I invite every member of the Board to give an opinion, than that of our investments. I always ask my Board to co-operate and to give the best possible advice they can, which is given, and I take great care to see that it is properly carried out. Another question, and it is a very paltry one, to which he referred is the Directors' fees. If you want honourable and intelligent men to manage your business you must pay for them. There could be no better illustration of that fact than the history of this Company. This Company existed for four years without paying 1s. of dividend, besides being £100,000 in debt and very nearly falling into the hands of liquidators. The chairman of another company and I remonstrated, and endeavoured to bring about in a quiet manner, and without in any way disturbing the Board, a better state of things without effect. I then called together men in whom I had confidence, and we took your affairs entirely out of their hands. What has been the working of the Company since? The first six

Digitized by Google

months after we took possession we paid five per cent. per annum, and we continued to pay that until the beginning of the year, and, as you know, we have placed £310,000 to the reserve fund, and we have paid off £100,000 debentures. Surely it requires some little intelligence to do that. I do not mean to say a word against your former Board as to their honour or position, but when we are brought into contrast, and especially remembering that they had £1,000 more than we have, all I do say is that when you get good men you must pay for them. But I am sure all reasonable men will agree that this is not the time, when we are trying as earnestly as we can do to maintain your dividends—which I hope we shall be able to do by-and-bye—to raise so paltry a question. I would say, in conclusion, in support of what Mr. Newton said, if you are going to fight be prepared to fight—though it does not follow that you will have to fight. If we cannot get a respectable dividend for you in one way we will in another. As to the remarks of Mr. Griffith, I can only say that I have put my views in writing that they may go forth to Messrs. Mackay and Bennett and all other interested parties; and if Mr. Griffith had listened attentively to my address he would have found that the whole of it dealt with the question of getting higher dividends and coming to a satisfactory arrangement. I am opposed to fighting if it can be avoided; but I am good for a fight where it becomes a necessity. I hope that common sense in this case will prevail, and that the American gentlemen will see, as we see, the necessity for an amicable understanding. They are not a public company, they are gentlemen using their own private property, and they have not gone into this business, and put a million and a half into it, without expecting some return. I am sure they want to get money out of it, and I believe they will be only too glad to come to us and make such propositions as will enable them to make that something out of it, and we shall also profit by the arrangement. As to Mr. Griffiths' question about the reserve fund, it depends entirely on the amount we receive. We have increased our reserve a little last year, and we have taken that from the floating balance; but we have been particularly anxious to help the shareholders in these trying times as much as possible, and we have given them something which would otherwise have been placed to the reserve fund. I hope the crisis is one which will soon terminate. He then put the resolution, and it was carried. Continuing, he said: The next resolution that I have to move is "That The Lord Hawke be and is hereby re-elected a Director of this Company."

Mr. WILLIAM FORD seconded the motion, and it was carried.

The CHAIRMAN next moved "That Admiral of the Fleet the Hon. Sir Henry Keppel, G.C.B., D.C.L, be and is hereby re-elected a Director of this Company."

Mr. UNDERDOWN seconded the motion, which was also agreed to.

Mr. WEAVER next proposed:—"That Mr. John George Griffiths and Mr. John Sawyer be and they are hereby re-elected auditors of this Company for the ensuing year, at a remuneration of £50 each."

Mr. NEWTON seconded the motion, and it was carried.

Mr. NEWTON then proposed a vote of thanks to the Chairman and Directors, remarking that he was sure they were all charged with a proper amount of fighting power.

Mr. GRIFFITH seconded the motion, observing that it was owing to the present Board that the Company had been able to achieve any success.

The vote having been cordially carried,

The CHAIRMAN said: I thank you on behalf of my colleagues and myself. I believe we have all the same object in view. Mr. Guesdon's suggestion of reducing the Directors' fees by a small sum I may say would be but an infinitesimal benefit to the shareholders; but if there were any necessity for it I am sure the Directors would bend to it as readily as any of the shareholders. As to our policy, it is a clearly defined policy. Our object is to get higher dividends, and to obtain them we shall endeavour to bring about a termination of the present competition in every possible way by peaceful means. If we cannot bring it about in that way, then I am, with Mr. Newton, a fighting man, and I hope we shall carry the day without much loss to the Company.

The proceedings then terminated.

The Globe Telegraph and Trust Company (Limited).

The twelfth ordinary general meeting of the shareholders of this Company was held on Tuesday last at the City Terminus Hotel, Cannon-street, under the presidency of Mr. John Pender, M.P.

The SECRETARY (Mr. William Payton) read the notice convening the meeting, and the minutes of the previous meeting, which were confirmed, and signed as correct.

The CHAIRMAN: Gentlemen, you have had the report in your hands for some days, and I presume that you will take it as read. Before moving the first resolution asking you to approve of these accounts I shall, as usual, make a few remarks on what has occurred during the last year. The principal point of interest to-day is that the dividend on our ordinary shares this year is less than the last one by ¼ per cent., or 6d. per share. The cause of this, gentlemen, is not very far to seek. It arises from the falling off in the amount that we have received from the Anglo-Telegraph Company. In the financial year, 1883, the Anglo and Direct Company paid us £46,356, in 1884 they paid us £44,795, and in 1885, the present year, they paid us £38,467, or £6,218 less than the year ended 1884, which is sufficient to account for the 6d. reduction of our present dividend on the ordinary shares. Now, gentlemen, you will no doubt ask me what are the prospects in regard to the Anglo-American, because in regard to the other companies—the Eastern and the Eastern Extension—there has been a steady increase of income from them, and I see no reason to doubt that that income will be permanent. Therefore, so far as the Globe is concerned those who are holders in the Anglo-American Company are materially benefited, and those who are holders in the Eastern Company have had no reason to regret investing in the Globe Company. It has given them additional security, and I may say at the same time that the Eastern and Eastern Extension Companies have materially assisted in maintaining the dividend. I may also add that the Brazilian Company has been a good source of income, and I see no reason to doubt that that income will be maintained. As to the Atlantic Companies we are really passing through a crisis. There are more cables in the Atlantic than the public requirements demand. Some of these cables have been laid, in my opinion, without regard to returns. It may be in the spirit of ardent enterprise, or it may have been from some personal consideration, but nevertheless the cables are there, and we have to contend with them. I cannot believe that those who have placed their money in the Atlantic are likely to allow it to remain there without some return, and it will become a question, no doubt, with those companies to consider what is the best course to pursue to bring about such a return as we believe they are fairly entitled to. I am speaking now as one of the largest shareholders in the Anglo-American Company, because the percentage that we hold in that company is something like one-third of the capital. Therefore, upon the success or non-success of that company, very much depends a good or indifferent dividend for the Globe. We are very safe so far as the other companies are concerned, and we shall endeavour to use what influence we possess to bring about between the Anglo-American, Direct, and the other Atlantic Companies such an arrangement as will secure a better dividend than we are receiving to-day. It is not for me to use threats of any kind, because that is not business, but we shall try to act in such a way, and I hope we shall be successful, as to secure the real object that we have in view. It may be that we shall have to pass through six, or it may even be twelve, anxious months, and I do not say that we may not have a still lower dividend. But the question must be settled in such a manner as to give a fair and reasonable dividend, and when we get into that state the Globe will be in a position to pay the dividend, though it has not been a large one, which we have paid during the last few years. I may mention that although we have received during the last few years only 3 per cent. from the Anglo-American Company, we have paid 6 per cent. upon our preference shares, and at the rate of 4½ per cent. upon our ordinary shares. Taking the two together, that gives an average of 5¼ per cent. The object of the Globe was greater security for the shareholders, but greater security never means a very large dividend. However, I may simply state that I believe the shareholders of the other submarine companies are watching very closely the different interests which they represent, and I think the day is not very far off when we shall be able at all events either to open up negotiations with these companies, with a view to a better adjustment of our relations, or to decide upon such a course of action as will make business unsatisfactory for those who have what we consider entered upon our ground without any sound reason. The new cables that they have put into the Atlantic have been put there without any chance that I can see of their leading to profit. They are not required, and consequently instead of contributing to develop the traffic, they have simply taken away a portion of that which existed. They have done worse than that—they have reduced the rates, and consequently have thrown into the sea £150,000 by those reduced rates, from which they have derived no benefit whatever. With these remarks, I beg to move "That the report and accounts of the Directors for the year ended 30th July, 1885, submitted to this meeting, be and the same are hereby received and adopted; and that a dividend be now declared of 3s. per share on the preference shares, making, with previous quarterly payments, 6 per cent. on the preference shares, and of 3s. per share on the ordinary shares, making, with the previous distributions, a total payment for the same period of 4½ per cent."

Sir DANIEL GOOCH, Bart., M.P., seconded the motion.

Mr. WEATHERLEY said he had gone carefully into the accounts which had been presented to them, and he could not but think, if the other shareholders had the time or inclination to go through them, they would be very much surprised if they compared the accounts of 1874 with those of 1885. He thought they ought not to be content with a 4½ per cent. dividend when they should have, according to what the prospectus held out, one of 8 per cent. They all knew that in dealing with the Board they were dealing with experts in telegraph matters—gentlemen who had had a great deal of experience, and, as their honourable Chairman had said, if they had experienced men to manage their affairs they must pay for their services. In 1874 there were ten directors on the Board, and their remuneration was £1,000, which he considered very fair pay, but nearly all of those gentlemen were directors of two, three, if not four of the other cable companies in which they held shares. Now they had six directors, and their remuneration was £1,500. The salaries in the company in 1874 were £787, and in 1885 they were £1,425. Similarly, he found that the other payments had proportionately increased. Having entered into the details of the expenditure to prove his case, and to show that the dividend had fallen 1 per cent., he proceeded to say that there were 7,000 odd shareholders in the company, many of whom were clergymen and widows, who looked for their quarterly dividends; and he said that it was upon the faith of the prospectus originally sent out, announcing that they were to have 8 per cent. on their deferred shares, that those people had put their money into the Company, but now they saw what they ought to have in dividends dwindling away by increased expenditure. He concluded by moving an amendment to the effect that the proposed dividend be declared, but that the accounts be not passed until they should be examined by a committee of investigation to be afterwards appointed.

Mr. JOHN NEWTON asked whether the Company paid income-tax?

The CHAIRMAN said, in reply to the last question, that they did not, and that they had taken counsel's opinion upon the subject, and their

Digitized by Google

decision was that the income-tax should be deducted from the 6 per cent. preference shares, of which the ordinary shareholders got the benefit.

Mr. NEWTON contended that this was illegal, and that the money so deducted belonged to the Government.

Mr. PARNELL seconded Mr. Weatherley's amendment.

The CHAIRMAN: I am always pleased to hear criticism, more particularly when it is intelligent criticism, and bears practically upon the business of the Company. I must, in the first place, correct an error in Mr. Weatherley's statement. He spoke of a reduction of 1 per cent. in the dividend, and it is only ¼ per cent., which is a very material point.

Mr. WEATHERLEY: Pardon me, it was 5½ per cent. in 1874, and now it is 4¼ per cent.

The CHAIRMAN: You must never forget that we have now 7,500 shareholders to be dealt with, and that cannot be done at precisely the same expenditure as when you were dealing with 2,000. We have been constantly asked at these meetings to give as many details of the expenses as possible, and so we have tried to do. Again, we are not responsible for the new companies that have sprung up in the Atlantic. I think I can call gentlemen in this room to witness that we have in every possible way used our influence and power to prevent competition in the Atlantic. It is that competition alone that has reduced our dividend. I can truly compliment the Anglo-American shareholders who became shareholders in the Globe. Their dividend would have been 1 per cent. instead of what we are now paying. The Globe Company is not responsible for the management of other companies. We are shareholders in them, and why? The shareholders of those companies have exchanged their shares for Globe shares. They have not bought them with money; it has simply been an exchange, and that exchange necessitates a constant extension of our system. The salaries you say we have doubled. Well, admitting that we have, when we began with this Company we employed a smaller number of clerks, because we had a smaller amount of work to do. The salaries have been raised in the meantime, and we have had to increase the number of our office staff on account of the greater number of shareholders and the consequent increase of work. If Mr. Weatherley had been sitting by the elbow of our secretary when we were sending out our dividend warrants, and when everybody was in doubt as to what the income tax would be, he would have seen the number of calculations that had to be made, involving an amount of clerical labour that no one outside the office could form any idea of. As to rent and offices, I think no one would deny that ours is a very moderate rent for conducting a business with a capital of three millions. In respect to printing and stationery, I think the amount charged for them is small when you take into consideration the larger increase in the paper requirements of the Company. The item of postage stamps speaks for itself. As to the general office expenses, we might have given them, perhaps, more in detail. But I may here remark that the item of £249 includes a weekly audit by Messrs. Griffiths, Deloitte, Dever, and Co., which is a great protection to the shareholders. The legal expenses are £118. We pay our solicitor £100 a year. He attends every Board meeting. There are constantly questions cropping up in regard to what the other companies are doing, and we think it better to give this £100 a year than to give fees for each attendance according to the rate which solicitors charge. If we adopted the latter course we should pay in the long run a much larger sum than £100. In respect of the £18 in excess of that amount, it was spent, I may say, on counsel's opinion on this income tax question. [Mr. NEWTON: It was not worth the money.] I know there are men who would not differ very much from Mr. Newton on that point. But we took the opinion of the present Attorney-General and Mr. Rigby, and that opinion decided the matter in a way very much against some of our wishes, and we were bound to adopt that opinion or, as our solicitor tells us, make ourselves personally responsible. I may tell you that it is an adjustment—not a payment.

Mr. NEWTON: They why don't you pay that to the Government?

The CHAIRMAN: This question has been raised as if we were practising a fraud on the Government. Before we have our payments from these companies, the income tax is deducted and paid to the Government. It is perfectly straight, though there is a great deal of complication about it, but one thing is clear we don't rob the Government of 1s.

Mr. NEWTON: Certainly not, I do not say that you do.

The CHAIRMAN: On that point of legal fees I hope I have satisfied you. The whole of what Mr. Weatherley has complained arises from the question I have referred to, of the state of things in the Atlantic, for which we cannot be held to be responsible. Whatever influence we have will be exercised to bring about a better state of things, but anything like an inquiry into the expenses seems to me to be very unnecessary. Still, our solicitor tells me that the resolution moved by Mr. Weatherley and seconded by Mr. Parnell is in perfect order. As to the Directors' fees, I may mention that they were fixed by the shareholders in public meeting, and fixed at a time when they appreciated the value of the work of the Directors, and I have never heard until to-day any exception taken to them.

Mr. NEWTON said that it was thoroughly well known that no shareholder had fought so much against increasing the Directors' fees as he had, but he would rather that Mr. Weatherley withdrew his resolution, for he thought the Directors ought not to have any slight or censure passed upon them, for their services had been especially valuable to the shareholders.

The CHAIRMAN: I can only state this, that if there is anything meant to reflect in any degree upon the present body of Directors, they would not hold their position for one moment longer. I believe that we have served our shareholders well, and I think that the small interest which Mr. Weatherley holds in this Company would be very materially damaged if his resolution were carried to-day. This is a time when you require all the attention and energy of your Directors. You have honest men sitting on this side of the table. If you wish to have gentlemen who will always give way to your whims and ideas, your property will not be worth the paper on which it is written. The Company is in a thoroughly sound state. The companies we represent are thoroughly successful, and there is no immediate prospect of a very low dividend coming to us, and there is a very great prospect, if the property is properly handled, of our bringing about such a state of things in the Atlantic as will greatly benefit you. It is for you to support the gentlemen who have sat on this side of the table so long, and so honourably and faithfully looked after your interests. The course Mr. Weatherley is pursuing will have the effect of damaging your property.

A SHAREHOLDER: You invite us to criticise the accounts, and then when we proceed to move a resolution you say, "If you pass that you damage the property."

The CHAIRMAN: It is one thing to make a suggestion and quite another to pass a resolution such as this. One charge brought against your Board to-day is that of inviting proxies from the body of shareholders. We have not done anything of the kind. We have invited no proxies from the general body of shareholders. We have a very large interest on the part of those whom Mr. Weatherley so feelingly referred to, but I think their interests will be better secured in our hands than they would be if Mr. Weatherley's resolution were carried.

Mr. WEATHERLEY said that the Chairman, instead of giving him a satisfactory answer, had not satisfied him (the speaker) on any point. He maintained that the expenses were enormous, and that no satisfactory account had been given of the excessive increase under that head. The legal charges seemed to be exceptionally so, more especially in view of the fact that this was not a manufacturing concern where they were likely to have legal questions repeatedly cropping up. It was merely a trust where certain stocks and shares were held, for which, in due time, the money came in, and the dividends were sent out. Why on earth a solicitor was required at every Board meeting he did not know.

The CHAIRMAN: Mr. Weatherley has spoken of the enormous expenditure. Now, let that gentleman show me in any way where it is so extraordinary. He speaks of the solicitor's fees. I did not think that they were so very large; probably he knows more than I do about the subject. But we have considered in the interests of the Company that we should have our solicitor attending our meetings regularly, and that it is the cheapest way in the end. Will Mr. Weatherley point out where the expenses are enormous?

Mr. WEATHERLEY thought he had done so all the way through, and declined to go further into the matter. He was of opinion that now that the question of expenditure had been opened up, the shareholders ought not to dismiss it until they had some definite understanding that they would have a safeguard at least for the future outlay.

The CHAIRMAN: If this resolution is withdrawn I can state that we shall give every attention to satisfy Mr. Weatherley as to our accounts. If he, or any other gentleman, will call at the office between this time and the date of the next meeting, he shall get every possible information with respect to the accounts which it is in our power to give, and if he comes to the meeting and makes a practical suggestion we shall be glad to consider it.

Mr. NEWTON said that in deducting £35 income tax from the preference shareholders, the ordinary shareholders were charged something like £150 to £200. Therefore it was most unfortunate that they should have gone to the trouble of paying counsel £18 to enable them to deduct £35, at a cost of that amount.

The CHAIRMAN: The amount deducted is £2,886 11s. 5d., and that goes to the ordinary shareholders. He then read the original motion, and Mr. Weatherley's amendment.

Mr. BURT (the solicitor) suggested that the latter should be put as a substantive resolution after the report and accounts were adopted.

The CHAIRMAN objected, and said that such an investigation was calculated to cast a reflection on the Board.

Mr. BURT pointed out that the total expenses amounted to only 3l. per share.

A SHAREHOLDER thought that Mr. Weatherley should not press his amendment any further, after which there were cries of "Withdraw."

Mr. WEATHERLEY said that after such an expression of opinion he would withdraw his amendment, observing that he was content to call attention to the subject, and hoping that the next time they met the accounts would be prepared in a very different way, and that for the future, in the interest of the ordinary shareholders, every economy would be exercised.

The motion for the adoption of the report and accounts was then put, and carried unanimously.

Mr. SMITH wished to submit a resolution:—"That the Directors of this Company be instructed that no proxies of the Globe Telegraph and Trust Company should be given to the Directors of the Anglo-American Telegraph Company at a meeting of that company to be held at the Cannon-street Hotel on the 4th of August."

The CHAIRMAN: I am afraid you have come a little too late. Notice ought to have been given of this.

Mr. SMITH pointed out that the Chairman said they were not responsible for the loss of interest by the Anglo-American Company. He said that they were to a certain extent responsible, for if it had not been for their proxy at the last meeting, instead of £100,000 being added to the renewal fund, which he (the speaker) protested against, the Anglo-American Company this half year would have been able to pay a considerably larger amount than they did, and therefore the Globe Company would have been able to pay their proper and usual dividend. He was of opinion that they were responsible, especially when he saw three of the Directors of the Anglo-American on the Board of the Globe Company.

The CHAIRMAN: Your suggestion has come a little too late. I think I may state without any fear of breach of privilege that we, at a special meeting of the Globe Board, considered the question of giving proxies to

Digitized by Google

the Anglo-American Company. We have always on previous occasions given proxies; but there was a strong feeling on the part of the Board that the time had come at the present crisis that there should be a little more given to the shareholders and a little less to the reserve. I do not think that we should depart from the principle, which all men who understand submarine cables hold, that the reserve fund should be looked after, and that it should always be maintained as far as the income of the Company will allow. But we decided at the meeting to address a letter to the Anglo Board, requesting them to seriously consider the question of paying some more dividend to the shareholders. That letter was addressed to the Chairman, and I believe it had considerable influence on the decision of the Board, and that you owe, to some extent, the dividend the Anglo-American Company are going to pay to the influence of the Globe Board.

Mr. JOHN BROWN seconded Mr. Smith's resolution because of the abominable use the Anglo-American had made of the proxies of the Globe Company.

The CHAIRMAN pointed out that this was irregular. They would accept it as their opinion, but not as a rule.

Mr. NEWTON thought Mr. Smith was scarcely entitled to ask them to stultify their position as Globe shareholders at a meeting of the Anglo Company. They must bear in mind that Sir Daniel Gooch held nearly £100,000 of stock in this Company, and how was this Board to exercise its vote to please both Mr. Smith and Sir Daniel Gooch if they happened to be at issue with the Anglo-American Company. They could not exactly restrict the Directors from voting in the Anglo-American Company, and seeing that they had so far got Mr. Smith's views to prevail on the Anglo-American Board this half year, he thought Mr. Smith was to be congratulated on the success he had obtained in getting them to carry out the policy he had so persistently and consistently advocated at the meetings of the Anglo-American Company.

The CHAIRMAN then proposed, and Sir SAMUEL GOOCH seconded, the re-election of the Marquis of Tweeddale to his seat at the Board, which was agreed to *nem. con.*

On the motion of the CHAIRMAN, seconded by Sir JAMES ANDERSON, Mr. Henry Gooch was also re-elected to his seat.

The auditors having been reappointed,

Mr. WEATHERLEY asked whether it was the intention of the Board to carry out the original intention of the Board with regard to their having an intelligence department. He felt strongly about it, and thought that the Anglo-American Company might have been supported better by this Company if the intelligence department had been established.

The CHAIRMAN: I am very glad to see that you take an interest in this matter, but I think you have a great deal to learn of the difficulties which the Directors have to contend with. When you make a little careful study of the various questions, and you will come to us, we will discuss them with you, and if there is any practical suggestion you can make to us we shall give you every possible encouragement.

On the motion of Mr. WEATHERLEY a vote of thanks to the Chairman brought the proceedings to a close.

The Cuba Submarine Telegraph Company.

The twenty-eighth ordinary general meeting of the shareholders of this Company was held on Wednesday, at the Company's offices, 61, Old Broad-street, Mr. Joaquin de Mancha (the Chairman) presiding.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the report and accounts were taken as read.

The CHAIRMAN: Well, gentlemen, it is always pleasant for the Directors to meet their fellow-shareholders, and more particularly so when they have a very good account to render you, which they have to-day, and which I think the most fastidious cannot but consider as such. The accounts are so clear that it will require but a few words on my part just to go through a few of the items before I propose to you their reception and adoption. You will find that we are at peace with all our neighbours—even the Spanish Government, whom my friend Mr. Griffiths was rather doubtful about. They paid the money, which they acknowledged for a long time, but like many other impecunious people, although they acknowledged their debts, they do not always pay them. We have been more fortunate in this respect, and as you see, we received what we claimed for them, amounting to £1,137. With that and with the earnings of the half year we propose to recommend to you that a dividend be paid upon the ordinary shares of 10 per cent. The last time I had the pleasure of meeting you I almost predicted that this would be the case some day, but it has come upon us rather more quickly than I expected. But here it is, and I think the accounts are very favourable. The working shows an increase compared with the previous six months of last year. We have had about 2,000 more messages. Our income has not increased in that proportion, but still it is nearly £900 more than we had in June, 1884, and all the expenses are much about the same. There is a slight increase in the ordinary working expenses of about £160. We have been able not only to meet all our expenses, but to pay £2,000 towards the cable that we have purchased, and which we pay off gradually at the rate of £2,000 every six months. I think, taking everything into consideration, that we cannot but congratulate ourselves upon the prosperous state of our Company, which I hope will continue. Our cables are working fairly. They are, of course, getting a little antiquated, but still they are working as well as we could expect, and I hope they will continue to do so for some time to come. That, however, is one of those things which at any time we may have to face; we may be called upon to repair them more or less. This half year we have been particularly fortunate, we have had nothing to pay; whereas in the June of last year we had £2,000 to pay for the repairs that were then completed, and I therefore hope we shall not have any more great demands upon us. Of course there are sure to be some little amounts required to keep things in perfect order, and our manager in Cuba is so anxious and occupies his eyes so well with every minutiæ that I think we need not fear for any great outlay in that respect. With these few words, gentlemen, I beg to move "That the report and accounts now submitted be received and adopted."

Mr. ALEXANDER F. LOW seconded the resolution.

A PROPRIETOR asked whether the 1881 cable was to be paid for in ten amounts.

The CHAIRMAN, in reply, said the cable was to be paid for in twelve years. £17,500 had already been paid on account of it, and there was still £30,000 to pay.

Mr. THOMAS GREENWOOD remarked that the accounts were so clear that it was not necessary to enlarge upon them; and the shareholders were very much indebted to the Executive for the way in which they had conducted the business of the Company. Although the whole of the present prosperity could not be attributed to them, circumstances having favoured them, still it was quite possible for Directors, from want of judgment or otherwise, to spoil a good concern. That had not been so in this case. The property of the Company was improving much more rapidly than he had anticipated. It was possible if the traffic continued to increase, that they might be able to exceed the 10 per cent. dividend now earned. He hoped, however, the shareholders would be satisfied with the 10 per cent. until the reserve fund was largely increased to, say, 50 per cent. of the capital, or £110,000. They had still the heavy charges of the preference shares, and he thought the Board would be wise in endeavouring to merge in one the whole of the capital. It seemed to him unwise for small companies like theirs to have a divided interest. He did not propose to alter the status and privileges of the shares; but the preference shareholders might say, "We will take an ordinary share instead of a preference, though we will not do so unless we receive some compensation." In that event the Board might give them so much a share to make the conversion, out of their large reserves, which would be very suitable for such a purpose.

Mr. GRIFFITHS also thought it would be an advantage if any scheme could be devised for getting rid of the preferences. The preference holders had a prior security over all other claims on the income of the Company; and they could not get rid of them in a body without violation of the law. By some such scheme as the last speaker had mentioned, however, the Company might buy out the preference holders. He had attended all the late meetings of telegraph companies, and he could say that none of them had presented so satisfactory a report as the Cuba. All the other companies complained of the effects of the depression of trade, but he would like to know why this Company had not been affected by it? The Company had been prosperous for many years, and he believed it would go on and prosper.

The CHAIRMAN replied that the Company was not so much dependent upon the course of trade as were some of the others. There was a great deal of communication between Cuba and Spain. They did all they could to obtain business, but if bad times came upon them he hoped the shareholders would be as generous with them as they had been in times of prosperity. The Board would be ready to consider any well-devised scheme in respect to the preference shares.

The resolution was then put and carried unanimously.

The retiring director, Mr. Neil Bannatyne, was re-elected, as was the auditor, Mr. Greenwood.

Cordial votes of thanks were passed to the Chairman, Directors, Secretary and staff of the Company, and the meeting separated.

The Railway and Electric Appliances Company (Limited).

The second ordinary general meeting of the shareholders in this Company was held at the Cannon-street Hotel on Tuesday last, under the presidency of Colonel R. Raynsford Jackson.

The SECRETARY (Mr. William Shepherd) read the notice convening the meeting, and the report and accounts were taken as read.
